FEDERAL AID TO MEDICAL EDUCATION

A House committee is laying the groundwork for action in the next Congress on federal aid to medical education. With both the administration and the House Interstate and Foreign Commerce Committee showing interest in the subject, it should hold a high place on the health agenda of the session beginning in January. The committee staff, acting at the direction of the full committee, has written more than 50 organizations asking them for factual data bearing on medical education. The committee wants facts on the financial needs of medical schools and on the supply and demand for medical applicants and graduates "rather than arguments intended to support or oppose any particular form of federal aid." The committee staff letter adds that "this information should be available in useable form at the beginning of the 85th Congress to form the basis of the committee's further consideration of legislation to authorize federal aid to medical education."

President Eisenhower, in signing a recent measure for construction grants for nongovernmental research laboratories, said the measure was deficient because it did not include teaching grants. In medical and dental schools, he noted, space for research and teaching functions is so closely interrelated that no clear line can be drawn between them. The President then expressed hope that the next Congress would broaden the law to include grants for training facilities "which are essential in this period of rapid expansion of medical research." Secretary Folsom of the Department of Health, Education, and Welfare subsequently expressed disappointment also and promised the administration will continue to press for medical education legislation.

Under the heading of supply of students, the House committee is asking for information on (1) national training capacity of medical, dental, osteopathic, and public health schools, (2) training capacity by region and state, (3) utilization of foreign medical schools, (4) trends in supply of applicants, (5) admission policies, and (6) duration and cost to student of medical education. On the supply and demand of graduates, the committee cites (1) present and prospective numbers of medical school graduates, (2) licensure of graduates of foreign medical schools, (3) net increment in relation to population, and (4) examples of unmet needs in public programs, institutions, professional specialties, and rural areas. Concerning medical schools themselves, the committee asks these questions: (1) present costs and financing of operations of individual institutions, (2) effects of medical school financing on university financing, (3) expansion plans of individual institutions, and (4) state, regional, and private national programs and plans for helping medical schools and students.

MEDICAL SECTIONS OF REPUBLICAN PLATFORM

Health and medical sections of the Republican party's platform call for federal assistance to medical schools for construction and equipment, legislation for reinsurance and pooling arrangements to speed the expansion of voluntary health insurance, and vigorous development of atomic energy for medical purposes. The platform notes that the Eisenhower administration this year urged passage of the aid to medical schools bill but that Congress failed to enact it. Health and medical sections of the platform read as follows:

"The Republican party believes that the physical, mental, and spiritual well-being of the people is as important as their economic health. It will continue to support this conviction with vigorous action. . . . Republican action created the Department of Health, Education and Welfare as the first new Federal department in forty years, to raise the continuing consideration of these problems for the first time to the highest council of Government, the President's Cabinet. . . .

"We have fully resolved to continue our steady gains in man's unending struggle against disease and disability. . . . We have supported the distribution of free vaccine to protect millions of children against dreaded polio. . . . Republican leadership has enlarged Federal assistance for construction of hospitals, emphasizing low-cost care of chronic diseases and the special problems of older persons, and increased Federal aid for medical care of the needy. . . .

"We have asked the largest increase in research funds ever sought in one year to intensify attacks on cancer, mental illness, heart disease and other dread diseases. . . . We demand once again, despite the reluctance of the Democrat Eighty-fourth Congress, Federal assistance to help build facilities to train more physicians and Scientists. . . . We have encouraged a notable expansion and improvement of voluntary health insurance, and urge that reinsurance and pooling arrangements be authorized to speed this progress. . . .

"We have strengthened the Food and Drug Administration, and we have increased the vocational rehabilitation program to enable a larger number of the disabled to return to satisfying activity. . . . We shall continue to seek extension and perfection of a sound Social Security system. We pledge close cooperation with state, local and private agencies to reduce the ghastly toll of fatalities on the nation's highways."

From the Washington Office of the American Medical Association.

The platform pledges the party to "continuous vigorous development of atomic energy. . . . For the defense of our own country and to deter aggression, and for the promotion of world peace and the enhancement of our knowledge of basic science and its application to industry, agriculture and the healing arts. . . . President Eisenhower has inaugurated and led a strong program for developing the peaceful atom—a program which has captured the imagination of men and women everywhere with its widespread, positive achievements. . . .

"Every day, radioactive isotopes are brought more and more into use on farms, in clinics and hospitals, and industry. The use of isotopes already has resulted in annual savings of hundreds of millions of dollars and the nuclear age has only begun. It is to the benefit of the United States, as well as to all nations everywhere, that the uses of atomic energy be explored and shared."

MEETING OF COUNCIL ON RESEARCH FACILITIES

Sept. 20 has been set tentatively as the date for the first meeting of the National Advisory Council on Health Research Facilities, which must pass on money to be awarded under a new research grants program authorized by the last Congress. The council also will set policies and approve regulations. Members of the council now are being selected by Secretary Folsom of the Department of Health, Education, and Welfare.

The program provides for grants totaling 30 million dollars a year for three years to help in financing the construction of facilities for research in the "sciences related to health," which are defined in the act as including medicine, osteopathy, dentistry, and public health. Only public or nonprofit institutions are eligible, and the federal share of the project may not exceed 50%. Funds may be used for increasing research facilities through constructing and equipping new buildings or expanding, remodeling, or altering and equipping existing structures. The money may not be used for buying land, for offsite improvements, or to satisfy obligations incurred prior to award of the grant. Administration of the program is being handled by the Division of Research Grants, National Institutes of Health, Bethesda 14, Md.

PROGRESS IN ATOMIC RESEARCH

During the last six months new methods were developed for using atomic energy products and techniques to treat cancers, the effects of radiation upon living creatures were further investigated, and studies of methods of waste disposal yielded promising new knowledge, the Atomic Energy Commission's 20th semiannual report states. Research is being carried on in national laboratories and at projects sponsored by the commission in universities, colleges, hospitals, and other research institutions.

The report also describes a project for construction of a research hospital, to include a medical nuclear reactor, at Brookhaven National Laboratory on Long Island. The Brookhaven medical reactor, the first designed exclusively for medical research and treatment, will incorporate unique features to insure wider medical application of neutrons, flexibility of treatment, and availability of special short-lived radioisotopes. Completion is scheduled for 1958.

Announcement of another grant to make possible the completion of a nuclear research reactor to be used for medical research comes from the National Science Foundation. The foundation has awarded a grant of $500,000 to the Massachusetts Institute of Technology to help pay for a nuclear research reactor facility. Medical research planned for the MIT reactor includes the development of improved methods for treating brain tumors and other cancers by a neutron-beam therapy. The planned facilities will provide a higher neutron-beam strength than is presently available in other reactors and will furnish a down-directed beam that is preferred for the treatment of brain tumors.

The AEC helped assure safety and health protection at the 1956 spring weapons tests in the Pacific. A program to measure the radioactivity of sea water and marine organisms in the test area is being conducted. The marine surveys will continue as far as radioactivity is detectable in the ocean.

The AEC reported that it has continued its work with the Federal Civil Defense Administration, has kept its informative material in this field up to date, and is helping to provide local civilian defense groups with training tools. The commission also is expanding its scientific and technical assistance by adding consultant services to assist in civil defense matters. The report notes that "The Effects of Atomic Weapons," published jointly by the commission and the Department of Defense in 1950, is being revised to include the latest knowledge of weapons effects gathered by experiment and observation in laboratory work and test series since preparation of the first issue. Publication is planned for early 1957 under the title "Effects of Nuclear Weapons."

MISCELLANY

Dr. Theodore J. Bauer, a career officer in the Public Health Service since 1934, has been named deputy chief of the Bureau of State Services. He replaces Dr. Leroy E. Burney, recently appointed surgeon general of PHS. . . . The Korean GI Bill in its four years of operation has given 1,500,000 Korea veterans an opportunity to train for virtually every type of career and occupation found in America. Another one million veterans are expected to make use of their Korean GI training benefits before the program expires in 1965, according to VA estimates. One-third of all Korean GI trainees aimed for high-level professional, semi-professional, and technological occupations. Of the 156,000 Korea veterans who studied the sciences, 37,000 chose medicine and related subjects. . . . The Walter Reed Army Medical Center has named Lieut. Col. Herman A. Jones Jr., of Silver Spring, Md., as its new inspector general. Colonel Jones previously served in the office of the surgeon general. . . . The National Science Foundation has announced 289 grants, totaling $3,504,277, awarded during the last quarter of fiscal 1956 to help finance basic research in the sciences and the training of science teachers. The grants will also be used to help pay for conferences in support of science, for exchange of scientific information, and for attendance of scientists at scientific meetings abroad.

URINARY TRACT INFECTIONS CAUSED BY ANTIBIOTIC-RESISTANT COLIFORM BACILLI

William M. M. Kirby, M.D., Douglas O. Corpron, M.D.
and
Donald C. Tanner, M.D., Seattle

• *Nosocomial (hospital-acquired) infections are receiving increasing attention and are often serious when they occur, since micro-organisms that become widely disseminated in the hospital environment are frequently resistant to commonly used chemotherapeutic agents. The chief interest in recent years has centered around infections caused by Micrococcus (Staphylococcus) pyogenes var. aureus.*

The present study indicates that infections with antibiotic-resistant coliform bacteria may also occur commonly in hospitals. It is well known that catheterization and instrumentation of the urinary tract frequently lead to urinary tract infections, but the relationship of such infections to organisms present in the hospital environment is not commonly appreciated. The authors were unable to determine the source of the resistant bacteria and the exact mode of infection; the catheters themselves, and the solutions used to irrigate them, could not be incriminated. Blankets, mattresses, and possibly the nasopharyngeal flora of hospital personnel appeared more likely possibilities.

Results of antibiotic sensitivity tests from other hospital laboratories indicate that hospital-acquired infections with antibiotic-resistant coliform bacteria may be a widespread problem, and one that is largely unrecognized.

Infections caused by antibiotic-resistant bacteria have become a widespread and serious problem, chiefly with one organism, the Micrococcus (Staphylococcus). Such infections are usually acquired in the hospital, and an important focus is the nasopharyngeal flora of hospital personnel. Evidence concerning a similar increase in urinary tract infections caused by antibiotic-resistant coliform bacteria is conflicting. As pointed out in a recent comprehensive review by Finland,[1] except with streptomycin, originally sensitive strains have not been frequently observed to acquire high degrees of resistance during therapy. Much more commonly, sensitive strains have been eliminated by antibiotics and have been replaced by naturally resistant species, such as Proteus and Pseudomonas. In contrast to these results obtained in studies of individual patients, surveys from hospital laboratories have indicated a trend toward increasing resistance of coliforms, especially to tetracyclines.[2] A recent study from a general hospital laboratory revealed that more than a third of the coliform bacteria were tetracycline-resistant.[3] Our interest in resolving this discrepancy between the results obtained in individual cases and in hospital surveys was one of the chief motivations for the present study.

A study performed at this hospital two years ago showed that 29% of coliforms were resistant to tetracyclines and 43% to streptomycin.[4] It was postulated that resistant coliforms probably developed in patients with chronic infections as a result of therapy with these two antibiotics. Subsequent studies have shown that for the majority of patients this explanation is not the correct one. It appears, rather, that the patients somehow acquire infections with antibiotic-resistant coliform bacteria in the hospital, usually in association with instrumentation of the urinary tract. Details of these studies are presented in the present report.

Materials and Methods

During a three-month period, July through September, 1955, a study was made of all patients whose urine cultures, performed in the routine diagnostic bacteriology laboratory at the King County Hospital, showed a predominant growth of coliforms or of Achromobacter. Coliform bacilli were identified by their ability to ferment lactose with the production of acid and gas within 24 hours. No attempt was made to differentiate Escherichia coli from Aerobacter aerogenes. Members of the Achromobacter group were identified as described in our earlier publication.[4] After recovery of the etiological organism, antibiotic sensitivity tests were performed by the disk method with use of standards that have been found in this laboratory to correlate well with the tube dilution

Briefly, the highest concentrations of disks were

From the Department of Medicine, University of Washington School of Medicine, and the King County Hospital.

and the tests were performed on Mueller-Hinton medium. With few exceptions coliforms were either highly sensitive or quite resistant to a given antibiotic. For example, organisms sensitive to chloramphenicol or tetracyclines gave zones of inhibition larger than 20 mm. in diameter and were inhibited in tryptose phosphate broth by 5 mcg. per milliliter or less. With resistant coliforms, on the other hand, zones of inhibition were under 15 mm. in diameter, and, with the tube dilution method, growth occurred in the presence of 50 mcg. per milliliter of the antibiotic. Bacteria sensitive to polymyxin B, sulfisoxazole (Gantrisin) and streptomycin gave zone diameters greater than 10, 15, and 16 mm. respectively. The majority of the antibiotic-resistant coliforms showed resistance to the tetracyclines, chloramphenicol, streptomycin, and sulfonamides and were sensitive only to polymyxin B. Approximately one-third of the strains differed from this pattern in that they were also sensitive to chloramphenicol.

Patients whose urine cultures yielded coliform bacteria or Achromobacter were studied particularly in reference to the following points: (1) nature of the urinary tract infection, (2) possible underlying disease of the urinary tract, (3) instrumentation or inlying catheters, (4) previous antibiotic therapy, (5) location in the hospital, and (6) course of the illness. In addition to this study of all patients who had urine cultures during a three-month period, the antibiotic sensitivity pattern of coliforms isolated during various one-month periods has been tabulated on seven occasions during the past two years. Detailed observations have also been made on a number of individual patients whose cultures revealed antibiotic-resistant coliforms. Some of these cases are described below.

Results

One-fifth to two-thirds of the coliform bacteria olated at various intervals during the past two years found to be antibiotic-resistant according to the definition described above. No clear-cut reason could be found to account for the variation observed from month to month. During the course of the study, it became apparent that our original postulate, namely, that most antibiotic-resistant coliforms were cultured from the urine of patients who had had prolonged and varied chemotherapy, was incorrect. Although this undoubtedly occurs, another mechanism seems to be of greater importance. It appears that in most cases the resistant bacteria are acquired in the hospital, usually in association with instrumentation of the urinary tract and sometimes as a result of instrumentation elsewhere in the body. A few brief case reports will illustrate this point.

Case 1.—A 20-year-old woman was receiving a continuous intravenous infusion of penicillin for the treatment of subacute bacterial endocarditis and had been afebrile for two weeks. The penicillin was administered through an indwelling catheter in one of the veins of her left leg. On March 26, 1955, she had a shaking chill and a blood culture was positive for coliform bacteria resistant to all antibiotics except polymyxin B. A pour plate made from 1 cc. of the patient's blood contained 112 colonies of bacteria. The skin around the site of the cut-down was red and inflamed. She was treated with chloramphenicol, and the fever and swelling subsided within five days.

Case 2.—A 65-year-old female entered the hospital with a fractured femur on March 16, 1955. Initial urinalysis was negative, and she was not given antibiotics. An inlying catheter was inserted, and one week later the urine was noted to be cloudy. Urine was cultured on March 25th and revealed coliforms with a pattern of antibiotic resistance identical with that described in case 1.

These two patients, who were on widely separated wards of the hospital, appear to have been infected with the same organism. One infection was associated with a catheter in the bladder and the other, with a catheter inserted into a vein. Benzalkonium (Zephiran) chloride solutions used for bladder irrigations and for cleansing the skin for venipunctures were suspected, but cultures of these solutions were negative.

Case 3.—A 32-year-old female, 7 months pregnant, entered the hospital with acute bulbar poliomyelitis on Sept. 7, 1955, and was placed in a respirator. Urinalysis on admission was negative. A week after the insertion of an indwelling catheter, the urine was cloudy and antibiotic-resistant coliforms were cultured. Although an indwelling catheter was needed for only three weeks, these same organisms were cultured repeatedly from the urine during the next four months.

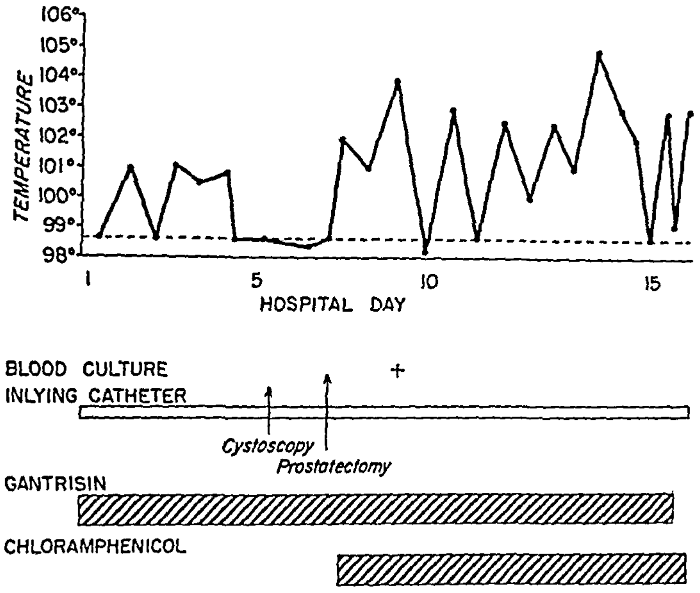

Fig. 1.—Therapy and course of patient in case 4.

Case 4.—An 82-year-old man with prostatic hypertrophy had had increasing difficulty in voiding during the previous six months and entered the hospital on July 27, 1955, with acute retention. He had received no chemotherapy. An inlying catheter was inserted, and he was given sulfisoxazole. He was cystoscoped on the sixth day, and two days later a suprapubic prostatectomy was performed. After surgery he developed shaking chills and a high temperature, and coliform bacteria sensitive only to chloramphenicol and polymyxin B were cultured from the blood stream (fig. 1). Despite therapy with sulfisoxazole and chloramphenicol, the febrile course continued, and he died on the 15th hospital day, after a massive gastrointestinal hemorrhage. At autopsy he was found to have multiple gastric ulcers and evidences of acute and chronic pyelonephritis.

In both of these instances, infection with antibiotic-resistant coliform bacteria seems clearly to have been acquired as a result of catheterization.

Case 5.—A 9-year-old boy, previously well, entered the hospital on Oct. 26, 1955, after an automobile accident. He was comatose and in shock and was taken to surgery, where a compound skull fracture was treated and a ruptured spleen was removed. An inlying catheter was inserted into his bladder, and he was treated with penicillin and chloramphenicol (fig. 2). The hospital course was stormy and febrile, and on the seventh day coliform bacteria sensitive only to chloramphenicol and polymyxin B were cultured from the blood stream. The pour plate showed a growth of 70 colonies per cubic centimeter of the patient's blood. The urine was cloudy and showed an increased number of red blood cells, white blood cells, and protein but was not cultured. During the second week, he showed gradual improvement, and on the 14th day he was transferred to another hospital. Follow-up data are not available.

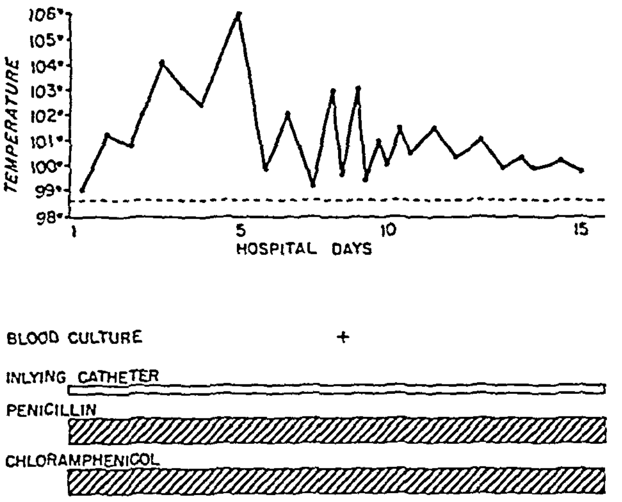

Fig. 2.—Therapy and course of patient in case 5.

In this instance, the coliform bacteria recovered from the blood stream had characteristics identical with those recovered in cases 3 and 4. These bacteria may have gained access as a result of the catheter in the bladder, although other possibilities are present, since he had two operations and also received continuous intravenous infusions of fluids and electrolytes.

Three-Month Survey.—From July 1 through Sept. 30, 1955, urine cultures from 85 patients revealed a predominant growth of coliform bacilli (see table). In 41 patients the organisms isolated were antibiotic-sensitive, and in 44 they were resistant. Approximately half of the resistant strains showed sensitivity only to polymyxin B, while the remainder were sensitive to both polymyxin and chloramphenicol. Striking differences were observed between the two groups of patients, as indicated in the table. The patients with antibiotic-sensitive organisms were in general those with acute urinary tract symptoms at the time of admission to the hospital. The incidence of obstructive lower urinary tract disease was low, and few had had recent catheterizations. It is of interest that 10 of the 41 patients in this group had bacteremia. In those with resistant bacteria, on the other hand, there was a high correlation with recent catheterization or instrumentation of the urinary tract. Many of these patients entered the hospital without symptoms of a urinary tract infection, and the urine became cloudy and infected only after an inlying catheter had been in place for several days. In this group the incidence of underlying urinary tract obstruction was relatively high, although, in a number of patients who developed infections in association with indwelling catheters, there was no evidence of underlying urinary tract disease. In only 6 of the 44 cases was it probable that the patient had had therapy with all the chemotherapeutic agents to which the bacteria were resistant.

Analysis of Patients Whose Urine Cultures Showed a Predominant Growth of Coliform Bacteria, or Achromobacter, Sensitive or Resistant to Antibiotics

	Coliforms		
	Antibiotic Sensitive	Antibiotic Resistant	Achromobacter
Total patients	41	44	14
Positive blood culture	10	1	1
Repeated catheterization or inlying catheter	4	42	13
Acute symptoms at time of culture	33	9	2
Obstructive lower urinary tract disease	5	25	8
Previous therapy with chemotherapeutic agents against which the bacteria were resistant	0	6	0

In 14 patients, the predominant organism cultured from the urine was Achromobacter. As noted in our earlier study,[4] this organism was cultured from the urine of patients with prolonged catheterization. In the one patient with a positive blood culture, the organism appears to have entered the blood through an infection around an intravenous catheter. This patient did not have a catheter in the bladder.

Comment

The present studies appear to clarify the paradox described in the introduction, namely, that, while coliform bacilli have not often been observed to acquire antibiotic resistance during therapy of individual patients,[1] surveys from hospital laboratories indicate that a relatively high percentage of all coliforms isolated from urine cultures are resistant to a number of chemotherapeutic agents.[5] The explanation seems to lie in the fact that the resistant bacteria are acquired in the hospital, chiefly in patients with indwelling catheters. The exact source of the resistant coliforms and their mode of entry into the body remain unexplained. One possibility is that the catheters themselves, or solutions used to irrigate them, become contaminated in the central supply area before they are sent out to the wards. This explanation is logical and attractive, but we have been unable to obtain any information to support it. Cultures of both catheters and irrigating solutions have consistently failed on many occasions during the past two years to show any evidence of contamination. Another possibility is that coliforms are carried in the nasopharyngeal flora of the hospital personnel in the same way as micrococci. Again, we have no convincing studies and further investigation along this line is contemplated. We have noted that coliforms are often isolated from the nasopharynx during carrier studies for micrococci, but antibiotic sensitivity tests have not been performed. If the nasopharynx is an important focus, the bacteria may multiply in the patient's intestine and may eventually gain access to the urinary tract by way of the intestine. Recent studies have shown marked changes from time to time in the serologic types of coliforms that inhabit the intestinal tract.[6] In patients with inlying catheters, interference with normal drainage may allow bacteria to pass through the lymphatic system from the intestine to the urinary tract. A study of the serologic types and antibiotic sensitivity patterns of coliform bacteria in the intestinal flora of hospitalized patients may well yield important information. A third possibility, probably the most likely of all, is that objects with which the patient comes into close contact, particularly mattresses and blankets, are heavily contaminated with resistant coliforms. The bacteria may then cover the patient's skin and the indwelling catheter and may gain access to the bladder when the catheter is irrigated. We have recently demonstrated that blankets and mattresses throughout the hospital are contaminated with antibiotic-resistant micrococci, and attempts to culture coliforms are now in progress.

As was true at the time of our earlier study,[4] members of the *Achromobacter* group were isolated from more than 10% of all positive urine cultures. This antibiotic-resistant gram-negative rod was also present almost exclusively in the urines of patients with indwelling catheters. The source and mode of spread of this organism is presumably similar to that of the antibiotic-resistant coliform bacteria.

To our knowledge, data similar to those obtained in the present study have not been previously published in the United States. It seems highly likely, however, that the phenomenon of hospital-acquired infections with antibiotic-resistant coliforms is widespread but is largely unrecognized. Failure to recognize the problem probably results from the fact that interest in urinary tract infections is focused chiefly on patients with acute infections acquired prior to admission to the hospital. In contrast, the present study started with organisms isolated in the laboratory and proceeded to an analysis of factors leading to infection of the individual patient. This approach automatically included patients, many of them relatively asymptomatic, who developed signs of infection only after they had been in the hospital for some time. The probability that the phenomenon is widespread is indicated by recent reports from other hospital laboratories, showing that one-third or more of the coliform bacteria isolated were antibiotic-resistant.[5] In some instances, coliforms resistant to several antibiotics are undoubtedly present in individual patients as a result of therapy with a variety of chemotherapeutic agents. As pointed out by Finland,[1] however, except with streptomycin, this has not often been observed to occur. It seems much more likely that in other hospitals, as in ours, future studies will indicate that in the majority of instances infections with resistant coliform bacteria are hospital-acquired. A rational approach to control measures will have to await a better understanding of the manner in which these infections are acquired.

The problem of nosocomial infections of the urinary tract is receiving increasing attention, and the subject has been recently summarized by Kass.[7] Particularly noteworthy are the studies of Orskov[8] in Copenhagen, who found a strikingly uniform distribution of Klebsiella strains cultured from the urines of patients on male surgical wards. Cross infection, probably related to catheterization, was considered the most likely explanation. Garrod and co-workers[9] in England found that almost 20% of women who had recently been catheterized had infections with enterococci, while only 2% of those not catheterized had similar infections. It is evident from these observations, and those described in the present report, that hospital-acquired infections of the urinary tract are an important and challenging problem. As with micrococci, the emergence of coliform bacteria resistant to most of the commonly used chemotherapeutic agents aggravates the situation and will undoubtedly make control measures difficult.

Summary and Conclusions

From one-fifth to two-thirds of the coliform bacteria isolated in the bacteriology laboratory at the King County Hospital at various intervals during the past two years have been found to be antibiotic-resistant. Study of the patients from whom they were isolated revealed that in most instances the resistant bacteria were acquired in the hospital, chiefly in association with instrumentation of the urinary tract. The source of the resistant coliforms and the exact mode of infection remain unexplained. Contamination of catheters and irrigating solutions could not be demonstrated. As with micrococci (staphylococci), the evidence suggests that resistant coliforms are widespread in the hospital environment and are available to cause infections when opportunities present themselves. Reports of a similar incidence of antibiotic-resistant coliforms from other laboratories indicate that this problem is probably present in many hospitals but is largely unrecognized.

PULMONARY CONGESTION AND EDEMA IN UREMIA

Skottowe W. DePass, M.D., Joseph Stein, M.D., Maxwell H. Poppel, M.D.
and
Harold G. Jacobson, M.D., New York

• *Roentgenograms of the chest in cases of so-called pulmonary azotemia, uremic lung, and uremic pneumonia show bilaterally symmetrical densities in the central lung fields with comparatively clear peripheral zones. The latter have been assumed, in the past, to be characteristic of the lung in uremia and to be absent when pulmonary congestion and edema arise from other causes.*

Study of roentgenograms previously published by others and of roentgenograms from a group of six original cases showed that the value of the clear peripheral zones as diagnostic criteria must be doubted; they were not always distinct in cases of uremia and were sometimes present when the primary disturbance was not renal but cardiovascular.

The roentgenographic appearances in question, therefore, should be interpreted simply as representing pulmonary congestion and edema due to fluid retention from whatever cause and should not be considered as diagnostic of nitrogen retention caused by renal failure.

It is the purpose of this study to deny the existence of the roentgenographic entity known as "pulmonary azotemia," "uremic lung," or "uremic pneumonia." It has been our observation that this so-called characteristic picture in patients with uremia actually represents pulmonary congestion and edema following fluid retention either on a cardiac or on a renal basis. The pulmonary changes seen are not related to azotemia, and identical changes can occur on a purely cardiac basis.

This pulmonary roentgenographic picture that occurs in patients with uremia has been described in the past and called variously pulmonary azotemia, uremic lung, or uremic pneumonia. In view of what is now known regarding the etiology of these roentgenographic findings, it would seem desirable to discard these terms. Alwall, Lunderquist, and Olsson [1] have suggested the term "fluid lung," since they consider fluid retention the basic factor in the changes seen.

The pulmonary roentgenographic findings in uremia that have been described consist of bilateral symmetrical densities in the central lung fields. The characteristic feature is the presence of a comparatively clear peripheral zone in both pulmonary fields. Most writers have admitted that, except for this peripheral zone of clearing, the findings are consistent with those of pulmonary congestion and edema.

Survey of the Literature

Roubier and Plauchu [2] in 1934 reported changes that were designated as uremic edema in the chest roentgenograms of four patients with uremia. Rendich, Levy, and Cove [3] in 1941 concluded that a positive diagnosis of pulmonary azotemia could be made from a roentgenogram of the chest. They considered the relationship of this picture to cardiorenal disease and nitrogenous retention as constant. However, they noted that this picture was rare and that there was no correlation with the level of blood urea. In 50 patients with elevated blood urea levels, roentgenograms did not show any pulmonary manifestations of uremia. These were all patients without clinical evidence of heart failure. It should be noted that all the patients reported in this study as showing the typical roentgenographic picture had clinical histories consistent with congestive heart failure. Doniach [4] in 1947 investigated four of five cases histologically. He also noted that the distribution of edema fluid in these cases was similar to that in uncomplicated acute left ventricular failure. His five cases all had clinical findings consistent with heart failure. The patients autopsied showed in the lungs widespread solid edema due to a fibrinous or albuminous intra-alveolar exudate. This was associated with a mononuclear cell reaction and organization with hyalin membranes lining the alveolar ducts. He considered this the result of a combination of a rise in pulmonary capillary pressure due to left ventricular failure and an alteration in capillary permeability resulting from the uremia. Barden and Cooper [5] in 1948 stated also that increased vascular permeability played a role in this condition. No definite evidence was offered to support this view. Bass and Singer [6] in 1952 reported five cases, all of which had clinical findings consistent with congestive heart failure. They considered the clinical findings in some of their cases less marked than would be expected from the roentgenographic picture. It was noted that the shadows gradually disappeared as the left ventricular failure was alleviated. Gould and Torrance [7] concluded that there was some correlation between the massive central type of edema and uremia. They included 10 "pure uremic" cases in their 100 cases of pulmonary edema. However, the case histories were not given.

Alwall, Lunderquist, and Olsson's [1] excellent work in 1953 reported 16 cases of uremia in which the chest roentgenograms revealed the so-called typical changes. They assumed that liquid retention constituted the fundamental etiological factor. In their series of patients they reduced fluid supply and produced diarrhea by means of hypertonic sodium sulfate solution either per os or as an enema. The body weight

Resident (Dr. DePass), Chief (Dr. Stein), and Consultant (Dr. Poppel), Department of Radiology, Veterans Administration Hospital; Assistant Clinical Professor of Radiology (Dr. Stein), Professor and Chairman of Radiology (Dr. Poppel), and Clinical Professor of Radiology (Dr. Jacobson), New York University College of Medicine; and Director of Radiology, Montefiore Hospital (Dr. Jacobson).

tract by way of the intestine. Recent studies have shown marked changes from time to time in the serologic types of coliforms that inhabit the intestinal tract.[6] In patients with inlying catheters, interference with normal drainage may allow bacteria to pass through the lymphatic system from the intestine to the urinary tract. A study of the serologic types and antibiotic sensitivity patterns of coliform bacteria in the intestinal flora of hospitalized patients may well yield important information. A third possibility, probably the most likely of all, is that objects with which the patient comes into close contact, particularly mattresses and blankets, are heavily contaminated with resistant coliforms. The bacteria may then cover the patient's skin and the indwelling catheter and may gain access to the bladder when the catheter is irrigated. We have recently demonstrated that blankets and mattresses throughout the hospital are contaminated with antibiotic-resistant micrococci, and attempts to culture coliforms are now in progress.

As was true at the time of our earlier study,[4] members of the Achromobacter group were isolated from more than 10% of all positive urine cultures. This antibiotic-resistant gram-negative rod was also present almost exclusively in the urines of patients with indwelling catheters. The source and mode of spread of this organism is presumably similar to that of the antibiotic-resistant coliform bacteria.

To our knowledge, data similar to those obtained in the present study have not been previously published in the United States. It seems highly likely, however, that the phenomenon of hospital-acquired infections with antibiotic-resistant coliforms is widespread but is largely unrecognized. Failure to recognize the problem probably results from the fact that interest in urinary tract infections is focused chiefly on patients with acute infections acquired prior to admission to the hospital. In contrast, the present study started with organisms isolated in the laboratory and proceeded to an analysis of factors leading to infection of the individual patient. This approach automatically included patients, many of them relatively asymptomatic, who developed signs of infection only after they had been in the hospital for some time. The probability that the phenomenon is widespread is indicated by recent reports from other hospital laboratories, showing that one-third or more of the coliform bacteria isolated were antibiotic-resistant.[5] In some instances, coliforms resistant to several antibiotics are undoubtedly present in individual patients as a result of therapy with a variety of chemotherapeutic agents. As pointed out by Finland,[1] however, except with streptomycin, this has not often been observed to occur. It seems much more likely that in other hospitals, as in ours, future studies will indicate that in the majority of instances infections with resistant coliform bacteria are hospital-acquired. A rational approach to control measures will have to await a better understanding of the manner in which these infections are acquired.

The problem of nosocomial infections of the urinary tract is receiving increasing attention, and the subject has been recently summarized by Kass.[7] Particularly noteworthy are the studies of Orskov[8] in Copenhagen, who found a strikingly uniform distribution of Klebsiella strains cultured from the urines of patients on male surgical wards. Cross infection, probably related to catheterization, was considered the most likely explanation. Garrod and co-workers[9] in England found that almost 20% of women who had recently been catheterized had infections with enterococci, while only 2% of those not catheterized had similar infections. It is evident from these observations, and those described in the present report, that hospital-acquired infections of the urinary tract are an important and challenging problem. As with micrococci, the emergence of coliform bacteria resistant to most of the commonly used chemotherapeutic agents aggravates the situation and will undoubtedly make control measures difficult.

Summary and Conclusions

From one-fifth to two-thirds of the coliform bacteria isolated in the bacteriology laboratory at the King County Hospital at various intervals during the past two years have been found to be antibiotic-resistant. Study of the patients from whom they were isolated revealed that in most instances the resistant bacteria were acquired in the hospital, chiefly in association with instrumentation of the urinary tract. The source of the resistant coliforms and the exact mode of infection remain unexplained. Contamination of catheters and irrigating solutions could not be demonstrated. As with micrococci (staphylococci), the evidence suggests that resistant coliforms are widespread in the hospital environment and are available to cause infections when opportunities present themselves. Reports of a similar incidence of antibiotic-resistant coliforms from other laboratories indicate that this problem is probably present in many hospitals but is largely unrecognized.

PULMONARY CONGESTION AND EDEMA IN UREMIA

Skottowe W. DePass, M.D., Joseph Stein, M.D., Maxwell H. Poppel, M.D.
and
Harold G. Jacobson, M.D., New York

• *Roentgenograms of the chest in cases of so-called pulmonary azotemia, uremic lung, and uremic pneumonia show bilaterally symmetrical densities in the central lung fields with comparatively clear peripheral zones. The latter have been assumed, in the past, to be characteristic of the lung in uremia and to be absent when pulmonary congestion and edema arise from other causes.*

Study of roentgenograms previously published by others and of roentgenograms from a group of six original cases showed that the value of the clear peripheral zones as diagnostic criteria must be doubted; they were not always distinct in cases of uremia and were sometimes present when the primary disturbance was not renal but cardiovascular.

The roentgenographic appearances in question, therefore, should be interpreted simply as representing pulmonary congestion and edema due to fluid retention from whatever cause and should not be considered as diagnostic of nitrogen retention caused by renal failure.

It is the purpose of this study to deny the existence of the roentgenographic entity known as "pulmonary azotemia," "uremic lung," or "uremic pneumonia." It has been our observation that this so-called characteristic picture in patients with uremia actually represents pulmonary congestion and edema following fluid retention either on a cardiac or on a renal basis. The pulmonary changes seen are not related to azotemia, and identical changes can occur on a purely cardiac basis.

This pulmonary roentgenographic picture that occurs in patients with uremia has been described in the past and called variously pulmonary azotemia, uremic lung, or uremic pneumonia. In view of what is now known regarding the etiology of these roentgenographic findings, it would seem desirable to discard these terms. Alwall, Lunderquist, and Olsson[1] have suggested the term "fluid lung," since they consider fluid retention the basic factor in the changes seen.

The pulmonary roentgenographic findings in uremia that have been described consist of bilateral symmetrical densities in the central lung fields. The characteristic feature is the presence of a comparatively clear peripheral zone in both pulmonary fields. Most writers have admitted that, except for this peripheral zone of clearing, the findings are consistent with those of pulmonary congestion and edema.

Survey of the Literature

Roubier and Plauchu[2] in 1934 reported changes that were designated as uremic edema in the chest roentgenograms of four patients with uremia. Rendich, Levy, and Cove[3] in 1941 concluded that a positive diagnosis of pulmonary azotemia could be made from a roentgenogram of the chest. They considered the relationship of this picture to cardiorenal disease and nitrogenous retention as constant. However, they noted that this picture was rare and that there was no correlation with the level of blood urea. In 50 patients with elevated blood urea levels, roentgenograms did not show any pulmonary manifestations of uremia. These were all patients without clinical evidence of heart failure. It should be noted that all the patients reported in this study as showing the typical roentgenographic picture had clinical histories consistent with congestive heart failure. Doniach[4] in 1947 investigated four of five cases histologically. He also noted that the distribution of edema fluid in these cases was similar to that in uncomplicated acute left ventricular failure. His five cases all had clinical findings consistent with heart failure. The patients autopsied showed in the lungs widespread solid edema due to a fibrinous or albuminous intra-alveolar exudate. This was associated with a mononuclear cell reaction and organization with hyalin membranes lining the alveolar ducts. He considered this the result of a combination of a rise in pulmonary capillary pressure due to left ventricular failure and an alteration in capillary permeability resulting from the uremia. Barden and Cooper[5] in 1948 stated also that increased vascular permeability played a role in this condition. No definite evidence was offered to support this view. Bass and Singer[6] in 1952 reported five cases, all of which had clinical findings consistent with congestive heart failure. They considered the clinical findings in some of their cases less marked than would be expected from the roentgenographic picture. It was noted that the shadows gradually disappeared as the left ventricular failure was alleviated. Gould and Torrance[7] concluded that there was some correlation between the massive central type of edema and uremia. They included 10 "pure uremic" cases in their 100 cases of pulmonary edema. However, the case histories were not given.

Alwall, Lunderquist, and Olsson's[1] excellent work in 1953 reported 16 cases of uremia in which the chest roentgenograms revealed the so-called typical changes. They assumed that liquid retention constituted the fundamental etiological factor. In their series of patients they reduced fluid supply and produced diarrhea by means of hypertonic sodium sulfate solution either per os or as an enema. The body w

in all patients was reduced owing to the loss of fluid. There was a marked parallelism between the reduction in the body weight and the regression of the roentgenologic changes, but no relationship was noted to the nonprotein nitrogen or bicarbonate values. These remained the same or rose after the removal of the excess fluid. The significance of fluid retention as an etiological factor was also elucidated by ligating the ureters of rabbits and subsequently giving intravenous infusions. Changes similar to those of the uremic lung in human beings appeared on chest roentgenograms. After ultrafiltration treatment, the chest roentgenograms were normalized and remained normal in spite of uremia progressing to death. They concluded that it would seem justifiable to reckon fluid retention as a basic factor in the changes seen on the chest roentgenogram. They stated that for practical purposes it would seem preferable to speak of fluid lung rather than of uremic lung, since the former gives an indication as to appropriate therapy.

In reviewing the writing on this subject it is of interest that, in examining the roentgenograms used as illustrations of this condition, many of those presented as typical do not actually present a peripheral zone of clearing. A great many show grossly enlarged hearts and appear to be quite consistent with a diagnosis of pulmonary congestion and edema.

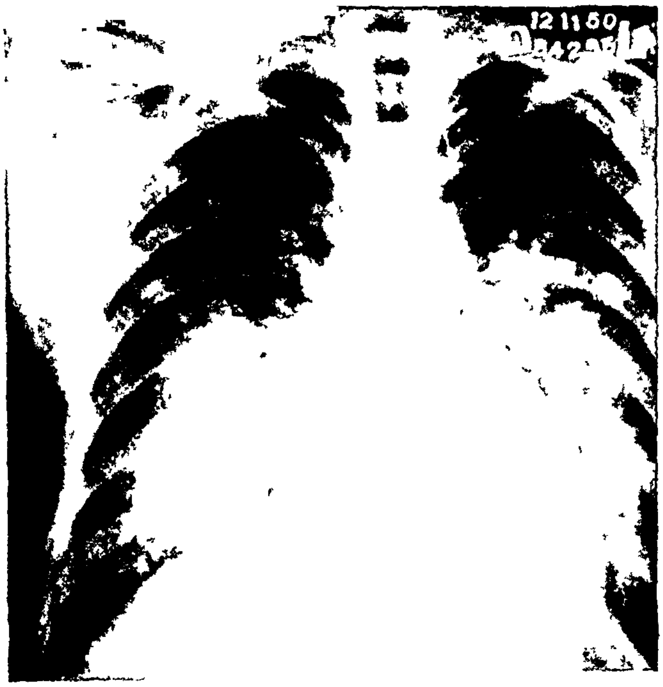

Fig. 1.—Roentgenogram of chest of patient in case 1; patient was in congestive failure at this time. Note clear periphery.

Report of Cases

The six illustrative cases summarized here were selected from the radiology museum of the Veterans Administration Hospital on the basis of chest roentgenograms that showed the so-called typical changes previously described in the literature.

Case 1.—A 27-year-old male was admitted on Dec. 7, 1950, with a history of chronic glomerulonephritis. He entered complaining of polyuria and headaches. Physical examination revealed venous distention in the neck. However, the lungs were clear on physical examination. The blood pressure was 230/150 mm. Hg. The hemoglobin level equaled 6.8 gm. per 100 cc. The urine showed 4+ protein with numerous red blood cells and white blood cells. The blood urea nitrogen level was 90 mg. per 100 cc. He was unable to retain fluids given orally, and it was necessary to give fluids intravenously. His urinary output was extremely low. He was receiving fluids intravenously on the day the chest roentgenogram shown in figure 1 was taken. At this time his respiratory rate was 28 per minute with severe hiccups. At autopsy two days later the lungs showed pulmonary edema. The right lower lung showed some fibrin and a few polymorphonuclear cells admixed, indicating an early pneumonia at this site. Autopsy confirmed the clinical diagnosis of chronic glomerulonephritis.

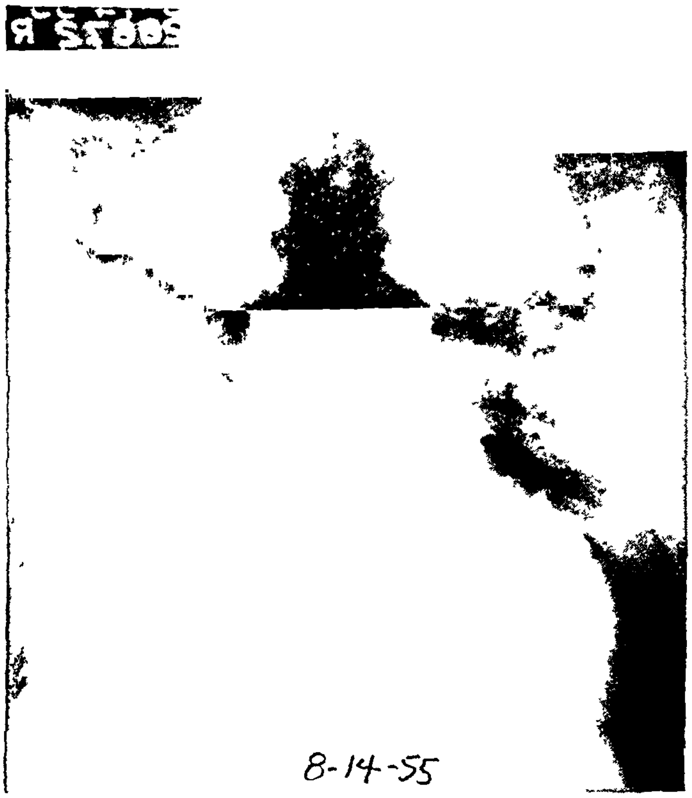

Fig. 2.—Anteroposterior roentgenogram of chest of patient in case 2 He was in congestive heart failure with a respiratory rate of 40 per minute at this time. The chest film cleared after digitalization.

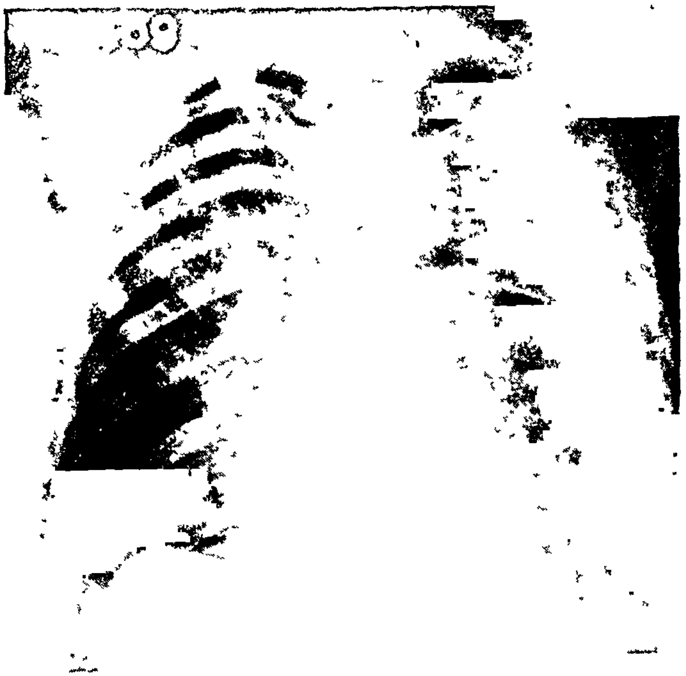

Fig. 3.—Roentgenogram of patient in case 3, showing hilar congestion with clear peripheral zone

Case 2.—A 50-year-old male entered the Veterans Administration Hospital on Aug. 10, 1955, with a two-day history of malaise, fever, chills, and cough. He had a history of hypertension and exertional dyspnea. On admission his temperature was 102.2 F (39 C), his pulse was 134 per minute, and his respiratory rate was 32 per minute. His blood pressure was 220/120 mm. Hg. On physical examination, rales were heard over the lower left lung field. The white blood cell count was 16,000 per cubic millimeter. The urinalysis showed 2+ protein with white blood cells and casts. The specific gravity remained fixed at 1.010. His cough was productive of purulent sputum. The blood urea nitrogen level was 42 mg. per 100 cc. Diagnosis of bronchopneumonia was made, and he was started on therapy with penicillin. Tetracycline (Achromycin) was added to the therapeutic regimen two days later. The dyspnea continued, and he developed a gallop rhythm three days after admission. The sputum became frothy and less purulent. On Aug. 14, 1955, when the chest roentgenogram shown in figure 2 was taken, his respiratory rate was 40 per minute. He was also receiving fluids intravenously on this day. His electrocardiogram revealed left ventricular strain. Digitalization and a low-salt diet were instituted. His blood urea nitrogen level rose to 92 mg. per 100 cc. on Aug. 15, 1955. A transient friction rub was heard at one time. His pulse rate and blood urea nitrogen level fell to normal after digitalization, and his respiratory distress was relieved. His chest roentgenogram showed marked clearing. It was felt clinically that the patient had entered with bronchopneumonia and chronic glomerulonephritis and that congestive heart failure had developed.

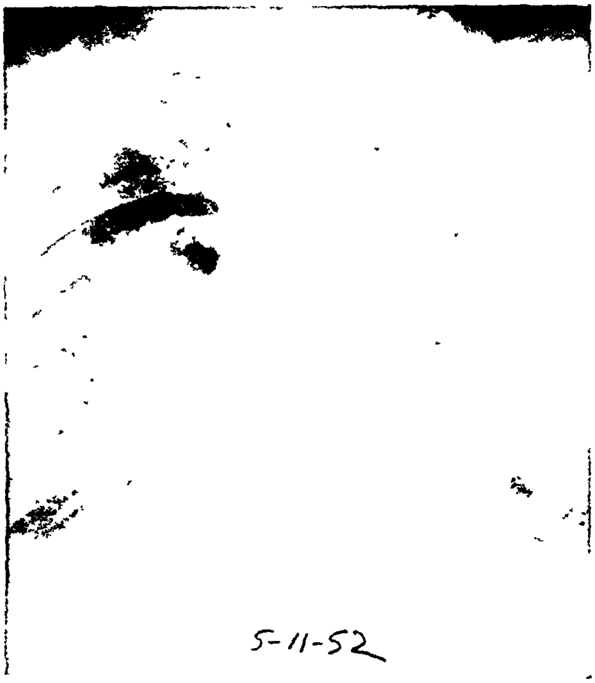

Fig. 4.—"Typical" roentgenogram of chest of patient in case 4, who had had a diagnosis of acute glomerulonephritis with congestive failure. Clearing followed digitalization.

Case 3.—A 24-year-old male was admitted on May 17, 1947, with chills and fever. His blood pressure was 175/40 mm. Hg, with a pulse rate of 120 per minute. An aortic systolic murmur was heard. His urine was clear. He was started on penicillin therapy. On May 29, 1947, he developed dyspnea and rales in his chest were heard. An electrocardiogram was consistent with myocarditis. He was digitalized; however, his course was progressively downhill. His blood urea nitrogen level rose from 99 mg. per 100 cc. on June 9, 1947, to 150 mg. per 100 cc. on June 20, 1947. On June 16, 1947, when the chest roentgenogram shown in figure 3 was taken, his respiratory rate was 40 per minute. He was receiving fluids intravenously on this day. At autopsy on June 24, 1947, endocarditis and aortic valvulitis were found. Pulmonary edema with some interstitial pneumonitis was present. The kidneys showed the changes of acute glomerulonephritis.

Case 4.—A 39-year-old male entered the hospital on May 11, 1952, because of exertional dyspnea and varicose ulcers. He also had a sanguinous discharge from the right ear that proved to be otitis media. Physical examination revealed marked dyspnea, but a clear chest was present. However, the admission chest roentgenogram showed marked changes (fig. 4). The respiratory rate was 28 per minute, the pulse was 120 per minute, and the blood pressure was 150/90 mm. Hg. The urine showed a specific gravity of 1.014 with 4+ protein. Microscopic examination revealed red and white blood cells with hyaline and granular

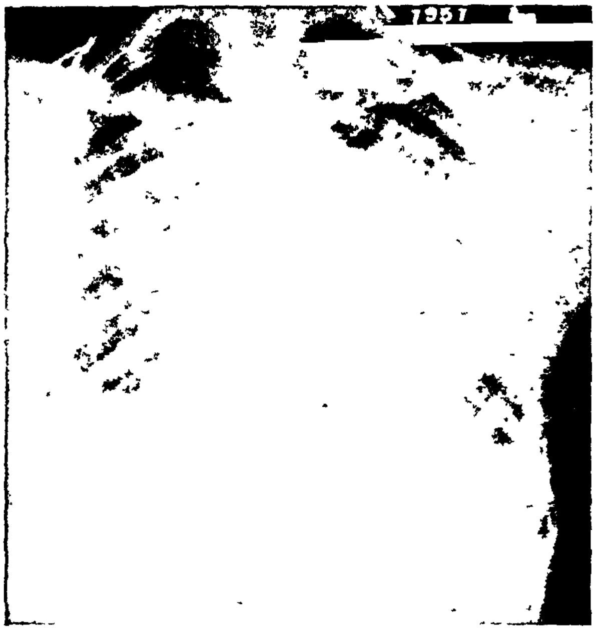

Fig. 5.—Roentgenogram of patient in case 5, showing "butterfly" densities with clear peripheral zone. The chest cleared after treatment for cardiac failure.

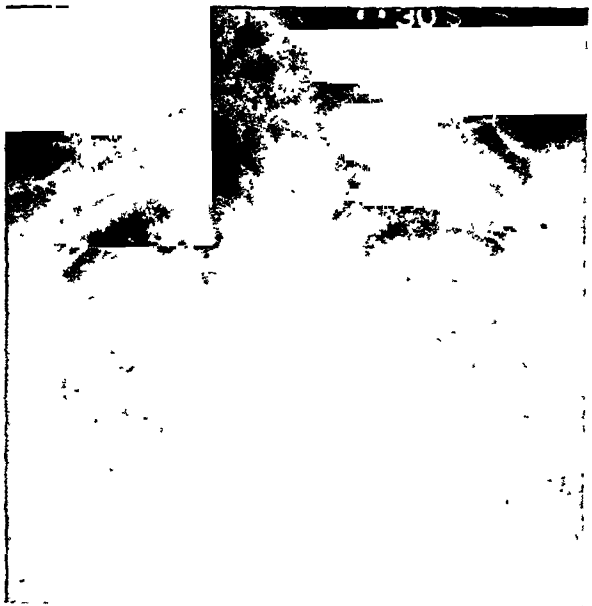

Fig. 6.—Roentgenogram of patient in case 6 in congestive heart failure with elevated respiratory rate. These changes occurred with no evidence of azotemia or renal disease. Chest films were normal after digitalization.

casts. The blood urea nitrogen level was normal. The dyspnea increased; distended neck veins were noted; and peripheral edema developed after admission. The dyspnea was relieved when the patient was digitalized and given diuretics. His weight dropped 23 lb. (10.4 kg.) within a week of digitalization. The chest roentgenogram cleared. The urine cleared, and a normal Addis count was present on discharge. The final diagnosis was acute glomerulonephritis with secondary hypertension and congestive failure.

Case 5.—A 33-year-old male entered the hospital on April 18, 1952, with a three-week history of cough and a one-week history of exertional dyspnea and orthopnea. He appeared acutely ill. His temperature was 102 F (38.9 C), his pulse was 102 per minute, and his blood pressure was 138/80 mm. Hg. The respiratory rate was 40 per minute. Distended neck veins were present. Moist rales were present, and a gallop rhythm was noted. Peripheral edema was present. The urine showed 4+ protein, many white blood cells, and a few red blood cells. The blood urea nitrogen level remained normal. The venous pressure was 130 mm. H₂O. Marked changes were seen on the admission chest roentgenogram (fig. 5). He was digitalized, given oxygen, and placed on antibiotic therapy. He developed a pleuropericardial friction rub. After digitalization he responded well, and his dyspnea was relieved. His chest roentgenogram cleared. He was afebrile within 48 hours. Serial electrocardiograms showed changes consistent with pericarditis. Red blood cells in the urine increased in number and then disappeared. He was discharged with a final diagnosis of acute glomerulonephritis with secondary congestive failure as well as superimposed bronchopneumonia. The patient was well one year later.

Case 6.—A 35-year-old male was admitted on Nov. 25, 1955, complaining of dyspnea and episodes of hemoptysis for six days. He had had recent ankle edema and gave a history of rheumatic fever. His temperature was 101 F (38.3 C), his pulse rate was 120 per minute and irregular, and his blood pressure was 130/100 mm. Hg. His urinalysis showed 1+ protein. His blood urea nitrogen level was normal. No rales were heard on admission, but marked changes were seen on his chest roentgeno- s (fig. 6). At this time his respiratory rate was 40 per te. His venous pressure was elevated. After digitalization symptoms were relieved, and his chest roentgenogram cleared. His urine became clear. The diagnosis was that of congestive failure on the basis of rheumatic heart disease with mitral stenosis and insufficiency. No evidence of renal disease was found.

Comment

Only three of these patients had uremia, but, as can be seen, all had symptoms consistent with congestive heart failure. There was clinical evidence of increased fluid volume in each case. The so-called typical uremic picture can occur on a cardiac basis without evidence of renal disease, as is demonstrated by case 6. It should be noted also that four of the patients showed some evidence of coexistent pneumonia. The frequent coexistence of cardiorenal pulmonary edema with superimposed infection is well known.[8] In one case, the pneumonia apparently preceded any evidence of clinical heart failure (case 2). The fact that excessive intravenous administration of fluids may be an important factor in the development of pulmonary edema has frequently been pointed out.[9]

The clear peripheral area was present on a chest roentgenogram taken during the course of each patient's illness. The explanation for the clear periphery has best been postulated by Dock.[10] He compared the lung to a fan that opens and closes about a relatively stationary hilus. In the central portion of the lung, the respiratory excursions are brief and stasis is greater. The edema fluid appears first in the inner zone where motion is slight compared to the periphery. It has been shown that a quiescent lung produces almost no lymph from the large collecting trunks. The lymph channels of the peripheral portions of the lung drain outward, and increased respiratory motion should aid drainage of these areas. Dock[10] suggested that acidosis and air hunger in these patients played the primary role. The elevated respiratory rates in the patients described at the time of the illustrated chest roentgenograms should be noted (see table).

The close association between glomerulonephritis with severe hypertension and cardiac failure has been described.[8] The frequency of heart failure in patients with acute glomerulonephritis is sometimes not appreciated. The question of the role of increased capillary permeability in nephritic edema has not been definitely settled. Fishberg[8] and others have suggested that augmented capillary permeability occurs due to the altered chemical composition of the blood in uremia. It should be noted that two of our patients who showed evidence of renal damage and fluid retention did not at any time have an elevated blood urea nitrogen level or other evidence of azotemia (cases 4 and 5). Only in those instances in which the edema fluid contains considerable amounts of protein are we justified in considering that increased capillary permeability plays a significant part in the genesis of the edema.[8] Warren and Stead[11] observed in patients with acute glomerulonephritis that the subcutaneous edema fluid contained levels of protein that were not elevated and were similar to levels that they observed in cardiac edema. They considered the cause of edema in acute nephritis to be water and salt retention secondary to a disturbance in renal function and not the

Summary of Clinical Data on Six Patients with Chest Roentgenograms Showing "Uremic Lung"

	Case No					
	1	2	3	4	5	6

result of diffuse capillary damage throughout the body. It would seem unlikely that the lung capillaries are selectively damaged. Peters[12] considered congestive failure to be the chief disorder responsible for edema in nephritis.

We believe that the primary cause of the changes seen in the chest roentgenograms of the patients with renal disease presented here appears to be water and salt retention as the result of the disturbance of renal function. The development of cardiac failure probably following hypervolemia, superimposed pulmonary infections, and elevated respiratory rate all play roles in the formation of the picture. The same roentgenographic changes can be produced by primary cardiac decompensation without renal disease. There is no such roentgenographic entity as a pure uremic lung.

Conclusions

We urge the abandonment of the terms "pulmonary azotemia," "uremic lung," or "uremic pneumonia" to describe changes seen in chest roentgenograms of patients with renal disease. The roentgenographic findings described represent, primarily, pulmonary congestion and edema. Fluid retention, varying degrees of cardiac failure, and often a superimposed pulmonary infection, as well as an increased respiratory rate, all enter into the formation of this picture. The six cases that are presented illustrate that there is no such roentgenographic entity as a "pure uremic lung."

USE OF THE C-REACTIVE PROTEIN TEST AS A SCREENING PROCEDURE FOR BLOOD DONORS

Edwin M. Knights Jr., M.D., Merrill Hutchins, Sc.B., Eugene Morgan, Sc.B.
and
Jaan Ploompuu, Sc.B., Detroit

• *The C-reactive protein test, performed by a capillary precipitin method with the use of commercially available antiserum, was applied to 3,543 blood donors and 633 patients in 37 different disease categories. The distribution of positive reactions failed to reveal any possibilities of the test as a screening method for the detection of any one condition in mass surveys. It was not of value in detecting carriers of homologous serum jaundice or in predicting minor transfusion reactions. Patients who experienced chills after transfusions developed a positive C-reactive protein test. Serums initially negative became positive after refrigeration and storage. The test represents a type of immune reaction but is unstable and nonspecific*

C-reactive or "acute phase" protein, which was first reported in the serums of patients with lobar pneumonia by Tillet and Francis[1] in 1930, has come into increasingly wide usage as a diagnostic tool since its isolation and identification by MacLeod and Avery[2] in 1941. The protein was originally recognized in the precipitate form when the C-polysaccharide of pneumococcus was added to the serums of patients ill with acute lobar pneumonia. Later, by injecting the purified protein into rabbits, MacLeod and Avery were able to develop an antiserum reputedly superior to the original C-polysaccharide. Wood, McCarty, and Slater[3] have been able to crystallize the protein out of lipid-containing fluids.

Although no great degree of specificity has been claimed for the C-reactive protein test, it has been described as a "non-specific but sensitive indicator of inflammation, of infectious or non-infectious origin."[4] It is relatively simple to perform and fairly easy to read if one does not attempt to make a quantitative determination out of it. Clinically, the C-reactive protein test has been most widely used in the evaluation of rheumatic fever, where it is considered most valuable in afebrile patients in whom carditis is a major feature. Good[5] summarized the advantages of the test over determination of the sedimentation rate for use in diagnosis of rheumatic fever in 1951, pointing out that there is no equivocal zone of values between normal and abnormal, that formation of C-reactive protein is not depressed by heart failure, that C-reactive protein is immunologically distinct from other serum protein, that concentration of the protein reflects roughly the degree of rheumatic activity, and that it may be absent from the serum in other conditions encountered in the differential diagnosis of rheumatic fever.

From the Department of Pathology, Harper Hospital

Attempts have also been made, although not on so great a scale, to assess the value of this test in other disease states. The possibility of its use in early diagnosis of myocardial infarction was suggested by Kroop and Shackman,[4] and the finding of a high percentage of positive tests in cases of cancer, tuberculosis, and rheumatoid arthritis has also been reported.[6] The apparent absence of C-reactive protein in the serums of 90 patients with active viral hepatitis was reported by Havens, Eichman, and Knowlton.[7]

Materials and Methods

In the present investigation, an attempt was made to evaluate the C-reactive protein test as a screening procedure for blood donors and as a basis of predicting so-called minor nonhemolytic transfusion reactions in recipients of blood. C-reactive protein determinations were performed by the capillary precipitin method devised by Anderson and McCarty,[8] with use of commercially available antiserum. Records were kept to ascertain whether positive C-reactive protein tests could be correlated with the sources of supply. Also under consideration was the possibility that the test might give some indication of the carrier state of serum hepatitis, particularly as the thymol turbidity and other liver function tests are not infallible as screening procedures. In addition, further studies were carried out investigating the nature and possible causes of false-positive C-reactive protein tests, together with incubation, bacterial inoculation, refrigeration, and Tiselius electrophoresis studies.

To accomplish these objectives, the C-reactive protein test was performed on the serums of all donors used by the David C. Whitney Memorial Blood Bank of Harper Hospital over a six-month period. Patients were followed to detect any changes in their C-reactive protein tests after receiving transfusions. The routine investigation of all transfusion reactions was augmented by a personal follow-up by one of us, and every effort was made to insure prompt and accurate reporting of any possible reactions. Criteria for minor reactions were shaking chills; urticaria, with or without an elevation of temperature; and the absence of hemolysis. A control series was run on patients with negative C-reactive protein tests who were receiving negatively testing bloods. It was usually necessary to exclude from the survey patients receiving multiple transfusions. All blood samples of recipients that had been received for typing and cross matching were placed in a deep freeze as soon as possible for retention for a period of at least six months.

Reading of the test was limited to two individuals on the investigative team. It was felt that there was probably little to be gained from making any attempt at quantitative evaluation, so, for the purpose of the studies, the test was reported as either positive or negative. In setting up the test it was found expedient to leave a small air bubble at the lower end of the capillary tube to prevent possible false-positive reactions that seem to arise from the plastic material at the base.

Findings

Early in the study it became apparent that the high percentage of positive tests among the patients to be studied represented a wide variety of disease states. A list of patients in whom the positive C-reactive protein tests were obtained is given in table 1. For the sake of completeness, this table also includes patients who did not receive transfusions but on whom the C-reactive protein tests were performed on admission or when ordered, as a diagnostic procedure. Follow-up of patients in whom results were negative revealed that many of their tests became positive while the patients were in the hospital. In a random sampling of 50 patients in whom the C-reactive protein test became positive, this occurred after surgery with transfusion in 28, after surgery without transfusion in 12, after parturition (no transfusion) in 7, and after transfusion alone in 3.

TABLE 1.—*Results of C-Reactive Protein Tests in Patients with Various Types of Diseases**

Diagnosis	Positive	Negative	Total
Rheumatic fever	18	10	28
Rheumatic heart disease	9	8	17
Rheumatoid arthritis	4	1	5
Congenital heart disease	0	7	7
Chronic valvular cardiac disease	0	6	6
Malignant tumors	24	29	53
Benign tumors	9	64	73
Brain tumors	0	4	4
Lymphatic leukemia	0	5	5
Bronchial asthma, bronchitis, bronchiectasis	5	6	11
Chronic and acute upper respiratory infection, sinusitis	5	6	11
Pneumonia	5	2	7
Appendicitis, acute	1	5	6
Tonsillitis, chronic	8	25	33
Nonmalignant gastrointestinal tract disease	5	13	18
Endometriosis, adenomyosis	0	13	13
Tuberculosis	2	3	5
Syphilis	2	1	3
Other acute and chronic inflammatory conditions	22	51	73
Traumatic conditions (fractures, sprains, etc.)	7	18	25
Pregnancy, ante partum	0	11	11
Pregnancy, post partum	87	5	92
Ruptured tubal pregnancy	1	0	1
Cataracts, preoperative	10	13	23
Simple hernias, preoperative	6	21	27

Cholecystitis, chronic	2	10	12
Thyroid colloid goiter	1	6	7
Adenomas (thyroid)	2	8	10
Hyperthyroidism	0	3	3

* Included are patients who received transfusions and patients who did not receive transfusions but had tests performed on admission or as diagnostic procedure.

Of the donors' bloods tested, 1,770 were drawn in the David C. Whitney Memorial Blood Bank from voluntary donors provided by the patients and from the bank's professional donor list. Of 3,543 bloods tested, 425 (12%) gave a positive C-reactive protein test; of these 425, 168 (approximately 40%) were in bloods drawn in the David C. Whitney Memorial Blood Bank and 257 (approximately 60%) were in bloods received from other metropolitan sources.

In a total of 100 C-reactive protein–negative tests in patients receiving blood transfusions, 29 became positive on the first day after transfusion. Seventy-seven had become positive by the fifth day after transfusion. These were divided as follows: 1. Eighty-three patients having negative C-reactive protein tests received negative bloods. By the first day after transfusion, 24 tests had become positive. By the third day after transfusion, 10 additional, or a total of 34, tests had become positive, and, by the fifth post-transfusion day, a total of 65 had become positive. 2. Seventeen patients having negative C-reactive protein tests received positive blood. By the first day after transfusion, 5 tests became positive; by the third day, 7 had become positive; and, by five days, 12 had become positive.

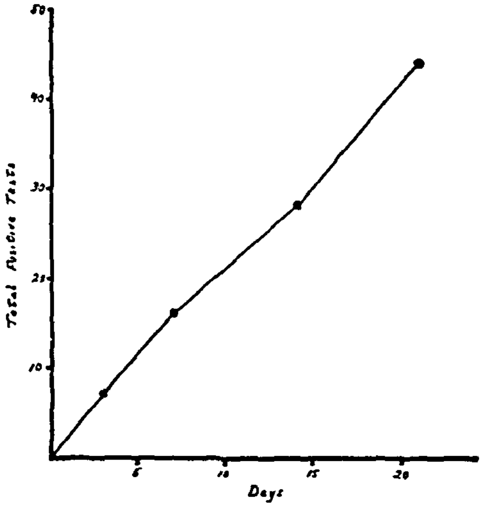
None of the above patients had major or minor transfusion reactions during this period. Twenty-two patients with C-reactive protein–negative tests had minor transfusion reactions, as evidenced by the criteria listed above. By the first day no tests were C-reactive protein–positive; by five days 16 were C-reactive protein–positive; and by eight days 18 were positive. In four patients, tests remained negative throughout this period; in none of these four were chills observed.

It was not too surprising that we were unable to establish any correlation between the positive C-reactive protein test and a carrier state of serum hepatitis, particularly after the report of Havens, Eichman, and Knowlton.[7] Five cases of homologous serum jaundice developed during the span of this survey. In four of these cases, patients had received 2 pt. (1,000 cc.) of blood each. Thanks to excellent cooperation from many individuals, serum was obtained from each of the donors concerned. In all eight donors, the liver function studies performed (thymol turbidity, icterus index, and cephalin flocculation) were within normal limits, but one donor from each case did have a positive C-reactive protein test. A fifth patient developed hepatitis after receiving blood testing negatively to the C-reactive protein antiserum.

The instability of this serologic examination became quite apparent during this research work and necessitated discarding large quantities of data. It was found that negatively reacting serums would become positive under several varieties of conditions. These are summarized below.

Retesting After Storage in Deep Freeze.—A group of 120 serums that had been negative and were subsequently stored in deep freeze at 15 C were retested in groups of 20 at various intervals. After 2 weeks, 16 had turned positive; after 4 weeks, one more; after 6 weeks, 10 more; after 8 weeks, 7 more; after 10 weeks, 7 more; and, after 12 weeks, 8 more. Bacteriological studies on these serums showed them to contain a multiplicity of organisms. Most commonly encountered were Aerobacter aerogenes, Streptococcus viridans, and Pseudomonas aeruginosa. Also encountered were diphtheroids, bacterioids, Micrococcus (Staphylococcus) pyogenes var. albus, and Escherichia coli.

Retesting After Storage in Refrigerator.—Another study was made to determine how long the serums could be kept in the refrigerator at 4 to 6 C. Fifty negative serums were placed in the blood bank refrigerator. Accurate records of the temperature were kept by means of a recording thermometer. These serums were tested at intervals, and the results are shown in the figure. Here again a large percentage of tests became positive. Bacterial contamination was again found with organisms similar to those described above. In addition, Proteus vulgaris was also observed.



Effect of prolonged refrigeration on 50 serums negative for C-reactive protein kept at 4 to 6 C. The number turning positive at 3, 7, 14, and 21 days are recorded above.

TABLE 2.—*Effect of Bacterial Inoculation on the C-Reactive Protein Test*

		Days				
Case	Serums	1	3	7	14	21

	Str. viridans	—	—	+	+	+
	Open tube	—	—	—	+	+
4	Sterile serum	—	—	—	—	—
	A. aerogenes	—	—	—	+	+
	Ps. aeruginosa	—	—	—	+	+
	Str. viridans	—	—	—	+	+
	Open tube	—	—	—	+	+
5	Sterile serum	—	—	—	+	+
	A. aerogenes	—	+	+	+	+
	Ps. aeruginosa	—	+	+	+	+
	Str. viridans	—	+	+	+	+
	Open tube	—	—	—	+	+

Study of Correlation Between Infecting Organism and Subsequent Positive Test.—In this study an attempt was made to discover if any correlation existed between an infection with a particular organism and a subsequently positive C-reactive protein test. Those organisms occurring most frequently, A. aerogenes, Ps. aeruginosa, and Str. viridans, were inoculated into sterile serum drawn through Swinny filter adapters. In addition, sterile control studies were run. Results are shown in table 2. As can be seen from the table, control serums did turn positive in spite of remaining bacteriologically negative; however, the organisms used tended to speed up the appearance of a positive C-reactive protein test.

Study of Effect of Inactivating Procedure Used in Serologic Studies.—In another investigation serums for which tests had become positive after refrigeration were studied to discover whether the inactivating procedure used in serologic studies might effect the final result in the C-reactive protein reaction. Twenty positive serums, representing 10 in which tests were positive directly after serum was taken from the patient and 10 in which tests had turned positive after refrigeration, were incubated in a water bath for 30 minutes at 37 C. They were then removed, and a C-reactive protein test was immediately set up. All continued to give positive C-reactive protein results.

Electrophoretic Studies.—In this study, blood was taken from 10 patients giving positive C-reactive protein tests and Tiselius electrophoretic studies were run on the serums of these patients. The Aminco-Stern apparatus was used, with a buffer of pH 8.6. Although various globulin fractions were found to be elevated in different patients, no characteristic pattern was observed.

Comment

It is apparent that the C-reactive protein test is a very nonspecific indication of an abnormal body process, such as acute inflammation or widespread neoplastic disease, although this does not appear to detract appreciably from its usefulness in evaluating the activity of rheumatic fever and possibly other disease states, such as bronchial asthma.

From the ubiquitous nature of acute phase protein in patients with diseases of all varieties, one might well suggest that this test be renamed "the heterophil precipitation test." Table 1 seems to corroborate the findings of Hedlund[9] of the vast varieties of disease stages in which a positive reaction may be expected. Although a positive test was found in many cases of malignant disease, these were, for the most part, far-advanced cases, and it should not be inferred from our data that the test is of value in the early diagnosis of cancer. From our data it would appear that the appearance of C-reactive protein after commissurotomy is of no diagnostic value, as either the surgical procedure or the accompanying blood transfusions would usually be sufficient to account for its presence. As a screening test of blood donors, the results so far leave considerable room for speculation. There is little doubt that it can pick up disease states concealed or unrecognized by the donor, and from this standpoint it shows some promise, particularly as it is a relatively simple test to perform. It would also appear to be a rough indication of the age of the blood stored and possibly of bacterial contamination. It would appear that the test could prove a valuable method of evaluating the state of health of blood donors being utilized in various sources of blood supply. Thirty per cent of recipients had a positive C-reactive protein test prior to transfusion, and therefore these could not be used in the evaluation of the reactions. In contrast, only 12% of donors had positive tests. From all data available we must assume that, if the test has been carefully performed on fresh serum, a positive test reaction is usually indicative of a pathological state existing in the donor.

Are we, therefore, justified in giving this blood to a patient? It would appear that the final decision should be based on the findings of demonstrable changes in the recipient of a serious enough nature to justify screening out an additional 10 to 15% of bloods already collected. If the recipients of blood develop positive tests that can be correlated with transfusion reactions, production of bacteremia, subsequent development of homologous serum jaundice, or development of immune antibodies, the test would appear to be of considerable value. Only the latter, a sensitization of the recipient, seems to be implied by our results. From a clinical standpoint, this sensitization is difficult to evaluate, particularly as in many cases it is undoubtedly modified by the clinician who prescribed antihistaminic substances that may mask, although not necessarily eliminate, the reaction of the transfusion in the recipient. It seems unlikely that the change in the recipient from negative to positive reactions can be attributed solely to the greatly diluted small quantity of protein received in the positively reacting bloods, although it is conceivable that the breakdown of these bloods in the body may contribute to the number of recipients giving a positive reaction. As noted above, many of these patients had received negatively reacting blood. Further support to possible immune response is the fact that the majority of the patients did not have positive reactions within the first 24 hours after transfusion but showed subsequent positive reactions on the third and fifth post-transfusion days. In nine patients who returned three to five weeks later for follow-up studies, four tests remained positive. Every patient who experienced chills after transfusion eventually gave a positive C-reactive protein test.

In our studies we were unable to establish a correlation between the receipt of positive C-reactive protein blood and development of so-called minor reactions and homologous serum jaundice, although it is interesting to note that, in nearly all patients who clinically manifested minor reactions, C-reactive protein tests became positive. Adequate evaluation of this would require a coordinated survey involving several large institutions with active blood banks and very careful follow-up of all patients receiving transfusions. It would also seem desirable to study the effects of chemical blood sterilization on the C-reactive protein reaction in recipients of the blood so sterilized.

Summary

The C-reactive protein test has been studied to evaluate its possible use as a screening procedure for blood donors. In 3,543 donors' bloods tested, 12% gave positive C-reactive protein reactions. No correlation was observed between the receipt of bloods positive for C-reactive protein and development of so-called minor transfusion reactions. The test does not appear to be of value for screening carriers of homologous serum jaundice. The delayed development of a positive C-reactive protein test in patients receiving transfusions of both positively and negatively reacting bloods was observed in many cases. All patients experiencing chills developed a positive C-reactive protein test. This possibly represents a type of immune reaction. The frequency with which positive C-reactive protein tests appear after surgical procedures or blood transfusions renders the test of little use in evaluation of the postcommissurotomy syndrome. The ubiquitous nature of C-reactive protein is reaffirmed by the high percentage of positive tests observed. In addition, the instability of this test and its nonspecificity are pointed out by false-positive reactions occurring after storage in the refrigerator and deep freeze.

PREVENTION OF RECURRENT ATTACKS OF RHEUMATIC FEVER

PROBLEMS REVEALED BY LONG-TERM FOLLOW-UP

Bessie L. Lendrum, M.D., Chicago
and
Charlotte Kobrin, M.S.W., Bartlett, Ill.

• *The cardiac status of 100 children with a history of rheumatic fever was reviewed at yearly intervals after their discharge from an institution where they had participated in a program of accelerated rehabilitation. Many were found to be without continued (though available) medical care, to have stopped taking any prophylactic medication, or to have been set back seriously in their emotional, social, or economic adjustment. Sixty-four had definite evidence of heart disease, but this fact seemed to play no significant part in getting patients to remain under medical care. The initiative of the patient and his parents does not suffice. Success in preventing recurrences depends on the development of a community-wide program, including some professional education and the dissemination of information about current rheumatic fever research.*

In 1949 a follow-up study was begun to evaluate the cardiac status of children who had participated in the Herrick House program of accelerated rehabilitation [1] after an acute attack of rheumatic fever. Herrick House is an institution where youngsters (ages 6 to 15 years) convalescing from rheumatic fever are made ambulant fairly rapidly once the clinical manifestations of the acute rheumatic processes have disappeared. At intervals starting one year after their discharge from Herrick House, these children are reexamined for evaluation only. In reviewing the data obtained on 100 children examined in 1955, three disturbing observations were made: first, almost one-third of the children were no longer under medical supervision; secondly, two-thirds of these 100 children were not receiving prophylactic medication; thirdly, adjustment problems at school and at home, which face the child who returns from Herrick House to his own environment, are not always successfully and most profitably dealt with. These observations led to a careful scrutiny of the data in an attempt to find out why these three situations occurred and how they could be prevented.

Findings

Discontinuance of Medical Care.—Twenty-nine of the 100 children were not under medical care. (It is of interest that, of 95 patients seen in 1949, 32% dropped out of medical care, approximately the same number as in this latest group.) Several possible explanations were considered, such as (1) lack of medical facilities, (2) lack of understanding by the patients and their parents of rheumatic fever as a disease process and what it means to them, (3) dissatisfaction with the

---

Research Director (Dr. Lendrum) and Social Worker (Mrs. Kobrin), Herrick House, Bartlett, Ill. Dr. Lendrum is now at Michael Reese Hospital, Chicago.

experience at Herrick House, or (4) lack of heart disease. Investigation, however, showed that none of these was the cause. There are available medical facilities, and every patient leaving Herrick House is either referred back to his private physician or given an appointment to the referring clinic. The significance of rheumatic fever to the patient is carefully reviewed with the parents by the admitting medical social worker. In addition, the medical director of Herrick House generally interviews the parents several times while their child is at the institution. He instructs them not only as to the current status of the child but also as to his future medical needs. The child, during the average stay of three months, is likewise thoroughly instructed as to how to cope with his medical problems. These careful educational efforts in themselves, however, have not proved adequate to ensure continued medical supervision for the rheumatic child.

Dissatisfaction with the experience at Herrick House was also discounted as a factor in the failure of 29 patients to continue under medical care. On the contrary, although no services were offered to the patients at the follow-up examinations, the good will they and their family felt toward Herrick House resulted in an amazing degree of cooperation. Over 96% (100 out of 104) of the former patients asked to report for an examination did so not only willingly but also, some'mes, at great inconvenience and even financial cost themselves. This is certainly an indication that the atients and their parents had, by and large, an excellent relationship with the staff.

Incidence of Heart Disease at Follow-Up in 100 Children Treated for Rheumatic Fever

	Total Group Examined	No Medical Care; No Prophylaxis	Medical Care; No Prophylaxis	Medical Care; Prophylaxis
No heart disease	36	12	17	7
Definite heart disease	64	17	21	26
Totals	100	29	38	33

Lack of heart disease also did not appear to explain the failure to remain under medical care. Examination of the records showed that 17 of the 29 patients not in medical care had definite evidence of heart disease, and 3 of these 17 had severe heart damage (see table). Thus, in this group of 29, 41% had no evidence of heart disease and 59% had definite heart disease, of which 10% was severe. Similar grouping of the entire 100 patients showed that 36% had no evidence of heart disease and 64% had heart disease, of which 16% was severe. Accordingly, the percentage of patients with heart disease is about the same in the group without medical care as in the group under medical care. Even the severity of the heart lesion seems to play no significant part in getting patients to remain under medical care. It follows, therefore, from our experience that those patients with a history of rheumatic fever but with no evident heart disease are no more likely to drop out of medical care than those with definite heart disease.

The factors found to have been actually responsible for lack of medical supervision after convalescence were as follows: 1. Four patients not under medical care had attended pediatric-cardiac clinics until they reached the "age limit" for the clinics and were then discharged; they did not on their own initiative seek out adult cardiac clinics or private physicians for continued care. 2. Fifteen children got no medical care either because their parents could not accompany them to clinics for various reasons (such as daytime work, illness, or no one to care for small children in the home while attending the clinic) or because the parents were disinterested in following through on medical care. Often clinics have rules against seeing patients unaccompanied by parents even though the patient is willing to travel to the clinic alone and is old enough to do this. 3. Five patients did not continue under medical supervision because of their own rebellious and unrealistic attitudes. 4. Five patients dropped out for miscellaneous reasons, such as dissatisfaction with medical care, administrative error, physician's negligence, or patient's ignorance. It is of considerable interest that no great effort was needed to get 13 of these 29 patients who dropped out of medical care to return to a physician or a clinic. They did so after one interview, during the follow-up examination, with a physician and a social worker. This suggests that a simple follow-up system would significantly reduce the number of patients discontinuing medical supervision.

Lack of Prophylactic Medication.—The second major cause for concern was the observation that, of the 100 patients reviewed, 67 were not on a regimen of prophylactic medication as recommended by the American Heart Association (see table). Of these 67, 29 were not under medical care and, therefore, were not receiving medication. Though the remaining 38 were under medical care (24 under private and 14 under clinic care), they were not receiving the recommended daily oral doses of penicillin or sulfonamides or monthly benzathine penicillin G (Bicillin) injections. Of the 38 patients who were under medical care but were not receiving prophylactic medication, 47% had no heart disease and 53% had unquestionable heart disease, of which 10% was severe. The percentage of these patients with heart disease is not significantly different from that of the entire group of 100. Thus, the presence or absence of heart disease is not an adequate explanation of the failure to give prophylactic medication to those known to have had an attack of rheumatic fever.

Readjustment.—The third major cause for concern is more difficult to show by figures. It is well known that a serious, prolonged illness generally has some effect on the child's personality and on his subsequent readjustment to family, playmates, and school. Severe handicaps in readjusting to normal living may often result. Some of this is unavoidable, but much can be done to minimize or even prevent the resultant harm to the child. The program at Herrick House is specifically directed at minimizing adjustment problems. School teachers from the regular Elgin, Ill., school system conduct a full-time school program for all children at Herrick House as soon as they are no longer restricted to complete bed rest. The individualized attention possible in this setting not only permits the children to do as well as they do in their own schools but also often enables them to make up time lost due to illness. Under the guidance of a consulting psychiatrist and the director of Herrick House, the entire staff has become attuned to detecting and handling problems of adjustment to the group as well as the person's adjustment to his own problems, created or accentuated by his illness. Occasionally the severely disturbed children are treated by the consulting psychiatrist or by some other individual.

When the child is discharged from Herrick House, he no longer is dealt with by the staff there and is referred back to his own clinic or private physician. A full report on such aspects as school performance and adjustment, medical status, and adjustment problems is sent to the child's school and clinic in the hope that he will continue the progress he has begun at Herrick House. Despite these efforts, the follow-up study showed that occasionally a child who had been doing well at school at Herrick House, and who had been looking forward eagerly to continued progress in both his health and his total rehabilitation, met with sharp disappointment that might have been avoided. For example, a doctor who wished to "play it safe" and who was, of course, unaware of the child's functional capacity (as displayed at Herrick House, where he could be observed carefully for 24 hours a day) might have kept the child at home at rest or partial rest until the "next visit." As a consequence, the boy or girl who had been successfully and safely playing baseball, swimming, hiking, and attending school, with a doctor's permission, suddenly was disturbed by renewed doubts about his health. Patient's and parent's anxieties were rekindled. Occasionally, a child was forced, unnecessarily, to repeat a year's schooling. These two avoidable types of setbacks constitute severe blows to most children and can permanently cripple them emotionally, socially, and economically. Several children became so discouraged that they dropped out or school.

Comment

Need for Prevention of Recurrence.—The information acquired by examining children who had recovered from acute rheumatic fever is a powerful plea for a well-organized community program to prevent the recurrence of rheumatic fever attacks in patients who are known to have had rheumatic fever. It seems clear that no single institution can cope with a problem of such magnitude, and breakdowns in follow-up care will occur when the patient leaves the jurisdiction of the institution or private physician. Recurrent attacks of rheumatic fever can now largely be prevented. The devastating effects of chronic, incapacitating disease to the individual, his family, and his community are familiar enough to all who work with any aspect of the resulting problems. Accordingly, such persons as physicians, social workers, and educators note with great enthusiasm the reports of highly successful measures that are capable of almost completely preventing rheumatic recurrences. The occurrence of initial attacks of rheumatic fever can also be reduced by prompt treatment of streptococcic infections. The mechanism of pathogenesis of this disease process is still unknown, and complete prevention of initial attacks is still not possible. This, however, should not beguile workers in the field of rheumatic fever into focusing solely upon the unsolved problems and neglecting to apply what is already known in the effort to stamp out rheumatic fever.

By far the greatest need at the present time is to put into action machinery for effectively applying the measures that we know to be capable of greatly reducing recurrences in patients who have had rheumatic fever. Known rheumatic patients should remain under regular medical supervision and receive prophylactic medication. The physician and his co-workers in associated professions who participate in this important task will achieve the important goal of very greatly reducing the incidence of disabling heart disease. They will save the individual patient, as well as his community, the suffering from physical, emotional, and social problems that attend all chronic diseases. In addition, countless numbers of dollars will be saved for the patient and his community.

Community Program.—An adequate communitywide program should include several essential features. First, it must have a registry of all individuals in the community known to have had rheumatic fever. This registry can serve numerous functions, but the most important function will be that of promptly detecting all instances in which a known rheumatic patient fails to carry out recommended medical follow-up and treatment. Having such a registry and the important information it supplies would permit implementing a successful prophylactic program. This can be achieved only if machinery exists for dealing with each instance of failure to follow the recommended medical program as soon as possible, so that no longer than a day or two elapses after a missed appointment before steps are taken to deal with the situation. For this part of the program each cooperating clinic would have its own resources and solutions. Communitywide integration is needed to take over the job where the clinic or private physician cannot cope with it. The health agencies that would assume this responsibility would, of course, vary from community to community. The board of health, local heart association, school health department, Public Health Service, voluntary groups interested in rheumatic fever, or a committee organized by the local medical society are a few agencies that might accept the responsibility for integrating the program. Whichever one the responsible agency might be, however, it will urgently require facilities for personal casework with delinquent patients. Those who perform this service may be nurses or social workers. The job will not profitably be confined to helping the patient keep his medical appointments or take his medicaments; a very important task would be that of helping a convalescent patient during the critical early days of his return to his own home and school or work environment. Many cardiac neuroses can be avoided by a bit of thoughtful help at this point. Implied, of course, is an educational program to be directed at the parents, clinic physicians, private physicians, and school teachers in order to supplement the actual individualized work with the patient.

Efforts likewise would need to be directed toward keeping the busy practicing physician informed of the experience at Herrick House, or (4) lack of heart disease. Investigation, however, showed that none of these was the cause. There are available medical facilities, and every patient leaving Herrick House is either referred back to his private physician or given an appointment to the referring clinic. The significance of rheumatic fever to the patient is carefully reviewed with the parents by the admitting medical social worker. In addition, the medical director of Herrick House generally interviews the parents several times while their child is at the institution. He instructs them not only as to the current status of the child but also as to his future medical needs. The child, during the average stay of three months, is likewise thoroughly instructed as to how to cope with his medical problems. These careful educational efforts in themselves, however, have not proved adequate to ensure continued medical supervision for the rheumatic child.

Dissatisfaction with the experience at Herrick House was also discounted as a factor in the failure of 29 patients to continue under medical care. On the contrary, although no services were offered to the patients at the follow-up examinations, the good will they and their family felt toward Herrick House resulted in an amazing degree of cooperation. Over 96% (100 out of 104) of the former patients asked to report for an examination did so not only willingly but also, sometimes, at great inconvenience and even financial cost o themselves. This is certainly an indication that the atients and their parents had, by and large, an excellent relationship with the staff.

Incidence of Heart Disease at Follow-Up in 100 Children Treated for Rheumatic Fever

	Total Group Examined	No Medical Care: No Prophylaxis	Medical Care: No Prophylaxis	Medical Care: Prophylaxis
No heart disease	36	12	17	7
Definite heart disease	64	17	21	26
Totals	100	29	38	33

Lack of heart disease also did not appear to explain the failure to remain under medical care. Examination of the records showed that 17 of the 29 patients not in medical care had definite evidence of heart disease, and 3 of these 17 had severe heart damage (see table). Thus, in this group of 29, 41% had no evidence of heart disease and 59% had definite heart disease, of which 10% was severe. Similar grouping of the entire 100 patients showed that 36% had no evidence of heart disease and 64% had heart disease, of which 16% was severe. Accordingly, the percentage of patients with heart disease is about the same in the group without medical care as in the group under medical care. Even the severity of the heart lesion seems to play no significant part in getting patients to remain under medical care. It follows, therefore, from our experience that those patients with a history of rheumatic fever but with no evident heart disease are no more likely to drop out of medical care than those with definite heart disease.

The factors found to have been actually responsible for lack of medical supervision after convalescence were as follows: 1. Four patients not under medical care had attended pediatric-cardiac clinics until they reached the "age limit" for the clinics and were then discharged; they did not on their own initiative seek out adult cardiac clinics or private physicians for continued care. 2. Fifteen children got no medical care either because their parents could not accompany them to clinics for various reasons (such as daytime work, illness, or no one to care for small children in the home while attending the clinic) or because the parents were disinterested in following through on medical care. Often clinics have rules against seeing patients unaccompanied by parents even though the patient is willing to travel to the clinic alone and is old enough to do this. 3. Five patients did not continue under medical supervision because of their own rebellious and unrealistic attitudes. 4. Five patients dropped out for miscellaneous reasons, such as dissatisfaction with medical care, administrative error, physician's negligence, or patient's ignorance. It is of considerable interest that no great effort was needed to get 13 of these 29 patients who dropped out of medical care to return to a physician or a clinic. They did so after one interview, during the follow-up examination, with a physician and a social worker. This suggests that a simple follow-up system would significantly reduce the number of patients discontinuing medical supervision.

Lack of Prophylactic Medication.—The second major cause for concern was the observation that, of the 100 patients reviewed, 67 were not on a regimen of prophylactic medication as recommended by the American Heart Association (see table). Of these 67, 29 were not under medical care and, therefore, were not receiving medication. Though the remaining 38 were under medical care (24 under private and 14 under clinic care), they were not receiving the recommended daily oral doses of penicillin or sulfonamides or monthly benzathine penicillin G (Bicillin) injections. Of the 38 patients who were under medical care but were not receiving prophylactic medication, 47% had no heart disease and 53% had unquestionable heart disease, of which 10% was severe. The percentage of these patients with heart disease is not significantly different from that of the entire group of 100. Thus, the presence or absence of heart disease is not an adequate explanation of the failure to give prophylactic medication to those known to have had an attack of rheumatic fever.

Readjustment.—The third major cause for concern is more difficult to show by figures. It is well known that a serious, prolonged illness generally has some effect on the child's personality and on his subsequent readjustment to family, playmates, and school. Severe handicaps in readjusting to normal living may often result. Some of this is unavoidable, but much can be done to minimize or even prevent the resultant harm to the child. The program at Herrick House is specifically directed at minimizing adjustment problems. School teachers from the regular Elgin, Ill., school system conduct a full-time school program for all children at Herrick House as soon as they are no longer restricted to complete bed rest. The individualized attention possible in this setting not only permits the children to do as well as they do in their own schools but also often enables them to make up time lost due tion of the private practice of medicine. What is done for the clinical department staff members has repercussions on the conditions of employment in other departments of the medical school and the rest of the university. While recognizing that some differential favoring the clinical staff members is indicated, the biochemists, pharmacologists, and anatomists find it difficult to understand why the surgeon should have an income many times their own. The full-time academic surgeon in turn sees the young men whom he has helped train go out into practice and in a short time exceed his earnings by sizable amounts. Furthermore, it taxes the ingenuity of university presidents to reconcile the salaries paid to professors of psychology, sociology, and English with those paid to the staffs of their medical schools. With the limited resources at his command, the medical college dean is forced sometimes to the consideration of complete abandonment of the full-time system and a return to a system of medical college staffing used at the beginning of the century, a step that would set medical education back in a harmful fashion. As a matter of fact, the full-time system as envisioned by Abraham Flexner in 1910 is just struggling along in many of our institutions. Many of our difficulties would be ironed out if we had a great deal more money, more than seems available at the present time.

The problems are complex and difficult and must be faced with fairness and equanimity. The medical profession has much to gain if our program of medical education remains vigorous and strong, and it has much to lose if our medical schools are weakened. All of us are into this together and must work it out in such a manner that the teaching of our future physicians and the members of allied health professions is maintained at a high level and is advanced whenever possible. In his address as President of the American Medical Association to the House of Delegates in Boston on Nov. 29, 1955, Dr. Elmer Hess [1] said:

> Another sore spot which has arisen in various parts of the country is the dispute over circumstances under which medical school faculty members are permitted to engage in the private practice of medicine as a means of supplementing income. This situation has created bad publicity in some of the cities I have visited. Surely, intelligent and temperate discussion of the problem within the profession would be more desirable than a public brawl. I understand that the Council on Medical Service is to make a progress report at this session on the exhaustive study of the problem which is being made in cooperation with the Council on Medical Education and Hospitals, the American Hospital Association and the Association of American Medical Colleges. Please let's work this out according to the needs of a given situation in a manner befitting intelligent, well-educated and mature men.

The medical school administrations must see to it that they do not compete unfairly with the practicing profession, and, by the same token, the profession should recognize the needs of our medical schools. Let us not confuse our code of medical ethics with medical economics. Medical schools must not exploit any members of their staffs, and, in turn, staff members must not exploit the institutions to which they belong.

Prof. Donald Fleming of Brown University has given an account of the differences of opinion held by the late Drs. Welch and Mall on the one side and the late Dr. Osler on the other.[2] It was in 1913 that Welch announced to the General Education Board that Johns Hopkins would institute a full-time system in the clinical departments, and the board then appropriated $1,500,000 to implement it. Fleming concludes his article by saying: "From 1913 forward to 1939 the principal objections to full-time for the leading men in clinical departments grew increasingly faint: and all progressive schools gravitated toward full-time." I shall not have time to discuss the factors that have made a core of full-time clinical staff members a necessity in our modern medical schools, but the demands of clerkships, undergraduate teaching, the development of outpatient departments for better teaching at all levels, the residency programs, medical research programs, and greater participation in community projects are known to all of you.

Definition of Full-Time Faculty Member

The word full-time has come to have a number of meanings, and we should bear in mind the definitions that accompanied the questionnaire under discussion. (The questionnaire discussed herein was prepared by the Council on Medical Service of the American Medical Association and was submitted to the deans of the 75 approved four-year medical schools and the 2 new four-year schools. It contained 13 major questions with subdivisions and dealt with the numbers, ranks, types of practice, and methods of compensating medical school faculties.)

A. An Absolute Full-Time faculty member has as his primary responsibility teaching and research activities in the Medical School and in its clinical facilities. His total income from professional activities is derived from the University and related sources. He may see and render care to pay patients only within the medical school and its clinical facilities, but his personal financial compensation from the Medical School is fixed without reference to such service. (It should be emphasized that he is not permitted to keep these fees. They are used by the university to support medical education and research.)

B. A Geographic Full-Time faculty member has as his primary responsibility teaching and research activities in the Medical School and in its clinical facilities. He receives a salary from the University and possibly from related sources, but he also has the privilege of receiving personal financial compensation for services rendered to pay patients, which he can care for in the clinical facilities of the medical school.

1. Geographic Full-Time, Unrestricted: No specific limit is placed (other than in keeping with the primary responsibility mentioned above) on amount of income derived from and/or time devoted to services to pay patients.

2. Geographic Full-Time, Restricted: A specific limit (over and above that related to the primary responsibility for teaching and research) is imposed by the University as to the amount of income that may be derived from and/or the time devoted to services to pay patients.

C. A Part-Time faculty member is a practicing physician who desires to devote part of his time to teaching and research in the Medical School and in its clinical facilities, for which he receives a nominal stipend. He maintains his own facilities for medical practice and is in no way responsible to the University in regard to where he sees pay patients, how many such patients are seen, nor how much income is earned.

D. A Volunteer faculty member is the same as a part-time faculty member except that, because of local tradition and/or amount of time and degree of responsibility involved, he receives no stipend from the University.

Current Practices

As I have visited medical institutions over this country and from experience in those where I have served, I have been much impressed by the contributions made by the part-time and volunteer faculty members. They serve an important function in community relations and in those with the outside profession, as well as what they do in teaching, research, and service. However, in general it may be said that they contribute most effectively in departments where there is full-time leadership; in my opinion, a proper balance between part-time and full-time staff is important for the effective functioning of a clinical department. One will find exceptions to a generalization of this kind.

It is fortunate that the study under discussion was undertaken, because it brings the practice of our various institutions out into the open. It shows how variable the methods of compensation are. It is to be regretted that adequate answers were not received from all the 75 approved four-year schools and the 2 new four-year schools to which the questionnaire was sent, but the 34 government and the 33 private schools on which the analysis was made give a good cross section of the nation's medical schools. The growth of the full-time system is indicated by the fact that 65% of government schools and 90% of private schools have a nucleus of absolute full-time clinical faculties. There are geographical full-time faculty members in 91% of the government schools and 84% of the private schools. Furthermore, 71% of government schools and 76% of private schools with absolute full-time clinical faculties permit private practice, although fees cannot be retained. However, it is extremely difficult to categorize these schools because of individual variations.

The fact that schools permitting private practice recognize a concern with the amount of such practice performed is shown by the methods of limiting it: placing ceilings on income, limiting time, limiting the number of patients, and limiting it to only referred patients. The most frequent limiting factor for absolute full-time faculty in government-owned schools is accepting "only referred patients" and in private schools "restricting the amount of income." In only a very small number of schools did the income of the absolute full-time staff members depend upon the number of private patients seen. It is significant that there is such a large percentage of schools using private patients for teaching purposes and that so many schools report that provision for private practice for the absolute and geographical full-time faculty members improves teaching and research. In my opinion, the most important finding of this whole study is that 25 of 34 government schools (73.5%) and 27 of 33 private schools (81.8%) believe that salary supplementation by fees from private patients is necessary to permit them to attract and retain competent full-time teachers. In addition, seven government and two private schools make the observation that it is partially necessary.

One point that should command attention in this discussion is the need for maintaining a balance of compensation in the various clinical departments. The surgeons and surgical specialists need less time to earn a given amount than the staff members in medicine, pediatrics, and psychiatry. This has been met in some institutions by group practice arrangements by which such inequities can be ironed out. At the fall meetings of the Association of American Medical Colleges, the following systems were described: the Full-time Plan at the University of Chicago, the Private Diagnostic Clinic at Duke University, the University of Virginia Plan, the University of Iowa Plan, and the Harvard University Plan. These plans and the many other ones that could have been described are different, but they work in each institution. In some of our state institutions, the full-time staff members, whether working on an absolute or a geographical full-time basis, are limited to work in tax-supported hospitals. This can lead to difficulties and misunderstandings with the outside profession. That a satisfactory solution can be worked out in such situations is admirably demonstrated in a number of government institutions.

Statement of Policy

For some time, many persons in medical education have looked forward to making a statement that would embody their judgment concerning the best policy for meeting the challenge facing medical education. The following statement was developed by a group from some of our medical schools and teaching hospitals and has been endorsed by the executive council of the Association of American Medical Colleges.

MEETING A CHALLENGE TO MEDICAL EDUCATION. The maintenance and improvement of the physical and mental health of the population are among the primary responsibilities of any nation. Health ranks in importance with other major features of the national economy, such as food supply, housing, employment, education, and industrial and agricultural production.

The level of any health service depends upon the competence of those who participate in it.

The future health of the people will depend in considerable measure upon the continuing supply of competent physicians. The education of physicians is a mutual concern of the universities, the medical schools, the teaching hospitals and the medical profession. The chief source of the supply of physicians will be the medical schools and teaching hospitals of the country.

In order that the high standards of medical education both for medical students and resident training may be maintained, it is essential that the universities, the medical schools, the teaching hospitals, and the medical profession appreciate the problems created for medical education by the changing pattern of medical and hospital services, a growing emphasis on medical research and the complexity of the operation of a modern teaching medical center.

The production of competent physicians by the teaching institutions will depend upon adequate facilities, financial support, the recruitment of a sufficient number of well-prepared students and particularly the maintenance of a staff of qualified scientists and clinicians dedicated to the education of physicians.

Prepayment plans for hospitals and medical services, which have shown a phenomenal growth in the last ten years, are having a pronounced impact upon the operation and financing of those services. The cost of medical and hospital services continues to rise so that prepayment becomes more and more necessary. The growth of knowledge with consequent specialization within the profession has introduced many new problems, partly answered by the evolution of group practice, preventive medicine and emphasis again upon the whole individual and family as the unit of medical care. All of these and other developments have produced considerable disruption in the older methods and forms of practice.

The hospital and medical service prepayment plans are sharply modifying an earlier concept of relying upon indigent patients in the hospital for the clinical instruction of medical students and residents. Medical Education requires a satisfactory volume and balance of clinical material in order that the high level of bedside instruction be maintained. The steady diminution of ward patients will require a continuing readjustment in our approach to the use of private patients and those covered by prepayment insurance plans to insure the instruction of medical students and residents.

Adaptations of medical and hospital services to the changing economic, social and professional conditions are to be expected. They have created apprehension and fear on the part of those who are obliged to meet new situations. These are evolutionary adjustments identified with progress, although new methods, just because they are different, are not necessarily better. These changes inevitably will have an impact upon the problems of professional education.

In view of the heavy duties upon the staffs, particularly in the clinical departments, many medical schools have put some of the appointments in those departments on one or another type of full-time status in order to insure proper instruction of students, the conduct of research and the supervision of patient care. These developments have increased the effectiveness of instruction, the productivity in research and the quality of patient care in the hospitals.

The teaching institutions which have the function of preparing the future generations of physicians should be encouraged to secure the services of full-time teachers and investigators under any reasonable plan satisfactory to the staff members and the school that will strengthen and improve the quality of medical education. They should have the support of the profession, the universities, and the hospitals in their endeavors to maintain the quality of teaching which, in turn, will insure a high level of health services for the future. The teaching centers associated with medical centers should be concerned with providing patient care of the highest standard, and, in doing so in an ethical manner, they should be free from hampering regulation and censure by the medical profession. The profession and the teaching institution should work together to encourage legislation which will not restrict the teaching centers in performing their essential functions in a modern society.

In closing, I again want to make a plea for understanding and consideration on the part of my colleagues, the medical administrators and educators, and the medical profession. If we cannot continue to work this out on a basis that is mutually satisfactory, the alternative is one that we do not wish to contemplate. The medical profession is helping our medical schools through the American Medical Education Foundation and the National Fund for Medical Education. Your help will be even more substantial if you continue to help make it possible for medical schools to remain strong by recruiting and holding competent faculties.

525 E. 68th St. (21).

ESSENTIALS OF A RESIDENCY PROGRAM IN GENERAL PRACTICE

Louis F. Rittelmeyer Jr., M.D., Jackson, Miss.

• *The need for highly competent personnel in the field of general or family practice will continue for some time. Changes in the medical school curriculum and improvements in internships must be supplemented by general practice residencies. In developing such residencies, the cooperation of the major specialty departments must be enlisted, but the advisability of accepting general practitioners as key men in the planning and supervision of these programs should be considered. The programs should be properly balanced. In institutions where residencies exist both for general practice and for specialties, the two types should be given equal standing and responsibilities. There must be no suggestion of inferior or second-rate training for the general practitioner, and competent family physicians must be permitted to make use of their training without the arbitrary restrictions too often placed on their activities.*

I would like to thank Dr. Kirklin and the Advisory Board for Medical Specialties for the invitation to speak to you today. It may have occurred to you—as it has to me—that the usual situation of a specialist addressing a group of general practitioners is reversed. I assure you that this general practitioner addressing this group of specialists is sincerely grateful for the opportunity but is not entirely comfortable in making use of it. The reason I am here is to share with you some of my ideas regarding residency training in the field of general practice. In sharing these ideas, I hope to give you one thing: my perspective. This then, is what one general practitioner thinks of graduate training for general practice.

This subject is relatively new. Until 1948, there was no organized effort to establish or standardize training past the internship for physicians who were preparing for general practice. At that time, the American Medical Association set forth the first Essentials of Approved Residencies in General Practice. In 1955, the Council on Medical Education and Hospitals joined with the American Academy of General Practice in creating a Residency Review Committee to approve programs of this type. This committee has also revised the "Essentials." These revisions have been accepted by the A. M. A. and the academy and are now in effect.

Several factors are responsible for this reawakening to the problem of training the family physician. As advances in medical science have made the practice of the art more complex and as the giant pyramid of specialty residencies has all but buried the internship in many places, it has become more and more apparent that a reappraisal of the needs of physicians preparing for general practice was necessary. The American Academy of General Practice, founded eight and one-half years ago, has been a major influence in the stimulation of this renewed interest in the educational needs of the family doctor.

Associate Professor of Preventive Medicine and Director of the Section on General Practice, University of Mississippi School of Medicine.

Read before the Annual Congress on Medical Education and Licensure, Chicago, Feb. 12, 1956.

It seems to me that this is an appropriate time to organize our thinking on the subject and chart our course for the future development of training programs for general practitioners. Let us consider these questions. First, is our goal clearly in view; do we know what we want to accomplish? Second, what ingredients must a residency have for official approval and for effective teaching? Third, how can the program be coordinated and integrated with the existing educational activities of the hospital?

Before attempting to answer these questions, I should like to mention that at the present time I am preparing a general practice residency for the University Hospital in Jackson, Miss. It is still in the blueprint stage. Obviously, I cannot give you any pat answers about how to operate a program. What I can tell you is how we are approaching the problems that are bound to arise in getting such a program under way. I should also like to state that, although I am a member of the Residency Review Committee for General Practice, I am offering these opinions as my own. I think the other committee members agree with most of these points, but I will not presume to speak for them.

What Is Our Goal?

Dr. Albert Dix,[1] of Mobile, Ala., speaking to the State Officers' Conference of the American Academy of General Practice last year, expressed our goal very well. He said, "In planning hospital training for the family doctor we must bear in mind the definite differences in his philosophy and that of the specialist. The specialist is to become more or less a finished product in a limited field. The family doctor is to become a growing organism, well planted but adaptable to an ever-changing situation. His education is truly a lifelong experience." Some of you may disagree with this view of specialty training. I would rather not argue that point. What I want to emphasize is this: for the generalist, the internship and residency are only the beginning—the foundation—of a larger educational experience that will continue for a lifetime. The purpose of a residency, therefore, is to make this foundation for future education and practice a firm one.

Since its beginning, the American Academy of General Practice has required postgraduate training of its members. I am sure you are aware of the healthy effect that this requirement has had in stimulating more and better postgraduate courses for family doctors. Last year the academy inaugurated a residency requirement for new applicants. This is not an absolute requirement, but only physicians with two years of approved residency training, in addition to one year's internship, are now eligible for active membership immediately upon entering practice. I have mentioned these postgraduate requirements to show how effectively the American Academy of General Practice has stimulated postgraduate education among its 20,000 members and to express the hope that the residency requirement will do as much for graduate training. For the first time, and I think this is significant, medical students are being given a clearly charted course to follow to qualify themselves as well-trained family physicians. It is more necessary now than it has ever been to provide them with residencies of high quality.

What Should a General Practice Residency Contain?

It is evident that no two hospitals can offer identical programs in a field as broad as general practice. Even if it were possible, it probably would not be desirable—individual needs vary too much. However, some standardization is necessary. These standards are set forth in the revised "Essentials." I will quote the part that specifies the ingredients that should be present:

> General practice residencies should be flexible, both as to content and duration, depending upon the special needs of the individual resident. It is recommended that residency programs be of at least two years' duration. In a two-year residency, the first year should be devoted to general medicine; i. e., internal medicine, the medical specialties, psychiatry, and pediatrics (including contagious diseases). The second year may be devoted to training in surgery, obstetrics and gynecology. The surgical fields to be covered ordinarily should include general surgery, traumatic surgery, fractures and operative gynecology. Any service offered during this second year must be of at least three months' duration.

As you can see, this is not a repetition of the merry-go-round of a rotating internship. The entire first year is devoted to the study of the whole patient. The second year may be devoted to surgery, obstetrics, or even narrower fields. Still, no service can be of less than three months' duration. This is intended to ensure against sincere but misguided attempts to cover too much territory too quickly. Generally speaking, the residency is divided equally between medicine and surgery, using those terms in a broad sense. I feel that it is important to place them in that order. A general practitioner's basic function as general manager of a family's medical affairs requires that his skill in diagnosis and medical management be good. Whether he will eventually do more surgery than he learns as an intern will be determined to some extent by the need in his community and by his own conscience. In any event, additional training in medicine, pediatrics, and psychiatry is helpful to all family doctors. Training in major surgery is a relative necessity and should, in my opinion, be sought only by those who intend to practice in areas where surgical consultants are not readily available.

I would like to call your attention to the sentences concerning surgical training. "Time devoted to general surgery and a surgical specialty should emphasize diagnosis, pre-operative and post-operative care, minor surgery and emergency care, but should also offer an increasing opportunity to assist with and perform common emergency and elective operative procedures. It should be recognized that there is limited educational value in a general practice residency in assisting with highly specialized surgical procedures of an advanced nature." In other words, if a resident in general practice wants to develop additional skill in handling common surgical conditions, he should be offered the opportunity. On the other hand, he should not be exploited by having to assist with complicated procedures that he will never perform.

Again quoting the "Essentials," "An important consideration in evaluating a residency program in general practice is the availability of adequate experience in the medical management of ambulatory patients. Hospitals that have no organized outpatient department should provide the resident with an opportunity to compensate for this deficiency, such as that provided in a home care program or preceptorship." The need for giving a prospective family physician experience in caring for outpatients is self-evident. Although an outpatient department is the usual means used to provide this training, it is not the only way. Preceptorship under a practicing family doctor for a month or more each year would be a valuable experience. A home care program throughout the resident's tenure would offer continuity and closeness in his relationships with patients and give him a great deal of insight into the problems of sick people.

An important consideration that has never been clearly defined is the status of general practitioners on the staffs of hospitals offering general practice residencies. Heretofore, the residency review committee has not insisted that general practitioners participate in the planning and conduct of these programs. However, in view of a recent action by the A. M. A. House of Delegates, this may change. The resolution states:

> *Resolved*, that, subject to review by Counsel of the American Medical Association, the representatives of the Association on the Joint Commission on Accreditation of Hospitals be instructed to stimulate action by that body leading to the warning, provisional accreditation, or removal of accreditation of community or general hospitals which exclude or arbitrarily restrict hospital privileges for generalists as a class regardless of their individual professional competence, after appeal to the Commission by the county medical society concerned.

I do not know where this action will lead as far as hospital accreditation is concerned. It would appear reasonable to suggest, however, that hospitals seeking approval of residencies in general practice should be prepared to accept general practitioners as key men in the planning and supervision of these programs.

How Does General Practice Residency Fit In?

In planning a general practice residency at the University Hospital, I have not solved all of the problems, but I believe I am aware of them. They are not too different from those encountered by others in activating similar programs. From my observations, relatively few pitfalls are most likely to upset a potentially good program. Taking the following steps should obviate most of these difficulties.

The first and most important step is to enlist the cooperation of the major specialty departments. A unique feature of the general practice residency is its dependence on physicians in other fields of practice to do a considerable portion of the teaching. Surgeons train surgery residents; internists train medical residents. These and many other specialists, as well as general practitioners, are needed to properly train general practice residents. They are doing this in 167 hospitals, including 8 affiliated with medical schools. The cooperative spirit with which these specialists have entered into this endeavor is tangible evidence that they are sincere in their desire to improve the standards of the family physician. Without their help, it would be impossible to have general practice residencies.

The second step is to give the program proper balance. Emphasis should be placed on activities that will best prepare physicians for family practice—not necessarily in those fields for which the particular hospital needs the largest house staff. If the patient load on any service is not sufficient to provide adequate experience for the resident, affiliation with another institution may well be used to fill this deficiency.

The third step is necessary only in hospitals that train residents in specialty fields. It consists basically of providing good training for both groups of residents by refusing to sacrifice the needs of one to the interests of the other. There are two facets to this problem. One involves a rather intangible, but nevertheless important, concept. The general practice resident should be given as much authority and responsibility as other first year residents. Every effort should be made to avoid letting him feel like a fifth wheel. The other facet of the problem is in integrating the general practice program with others being conducted. This is not difficult in medicine, pediatrics, and obstetrics, but may present some problems in surgical fields. It can be done and is being done in many hospitals. The solution usually entails no more than taking the trouble to work out a satisfactory formula.

Conclusions

It would be conventional to conclude this discourse with a summary of the facts and opinions I have presented. If my only purpose in speaking were to inform you of the requirements of a general practice residency, such a summary might be appropriate. However, I hope to do more than that, because I think it is vitally important for you to realize the urgent need for developing good graduate training programs specifically designed for future family doctors.

In 1954, Dr. Holland Jackson,[2] a general practitioner in Fort Worth, Texas, wrote: "What is at stake here is the development of a new man of medicine. If he can be achieved, all doctors will have the same level of medical education, and it will be high. There must be no suggestion of inferior or second-rate training for this new man of medicine."

The American Medical Association and the American Academy of General Practice have stated repeatedly that the one-year internship is no longer adequate to develop the full potential in a physician. Yet only 65% of the available positions in general practice residencies are filled. Too many hospitals are creating these positions for the convenience of the attending staff rather than the education of resident physicians. There are actually fewer doctors in general practice residencies today than there are in the fields of anesthesiology, ophthalmology, radiology, or urology. On Sept. 1, 1954, there were only 404 physicians in general practice residencies as compared to 20,090 training in specialty fields.[3] The new man of medicine will be a long time arriving at that rate.

The greatest problem facing American medicine today is how to provide our patients with modern, comprehensive care at reasonable cost. Fortunately, progress is being made. Medical schools are revamping their curriculums to better prepare their graduates to cope with the problems of patient care in our changing society. The internship is under constant scrutiny to help us find ways of improving it. Residencies in every specialty are being improved and enlarged with almost frightening speed. These accomplishments are remarkable and reflect great credit on the men and women who have worked so hard for their realization.

These efforts alone, however, will not produce the new man of medicine. And he is the man who will do more than any one else to fulfill the needs and demands of the American people. The future of the family doctor is the future of the free practice of medicine in this nation. To make sure he can fulfill his destiny should be the concern of every one of us. In the development of general practice residencies, we are still dragging our feet. We must awaken to the fact that the graduate education of the family physician is just as important as the undergraduate and postgraduate. An editorial[4] in THE JOURNAL of the American Medical Association last year expressed the problem clearly:

> Medical educators face the challenge of the needs in graduate education for those who choose this field and development of programs that will reflect the same thought and consideration that has been given to graduate medical education in the narrower specialty fields. Trends in specialization will not eradicate, in the foreseeable future, needs for well-qualified and highly competent personnel in the field of general or family practice. Is it not time, therefore, that every effort should be made to assure the same high standards of preparation for "specialists" in this important field as have been given to the preparation of personnel in the narrower specialties?

We need more general practice residencies and we need better ones. Students must be stimulated and encouraged to avail themselves of this type of training. And competent family physicians must be permitted to make use of their training in caring for their patients, without the arbitrary restrictions too often placed on their activities. This is as much your responsibility as it is mine. It is not too late, but there is no time to lose.

REVERSIBLE POSTOPERATIVE NEUROLOGICAL SYMPTOMS

REPORT OF FIVE CASES SECONDARY TO WATER INTOXICATION AND SODIUM DEPLETION

Lloyd G. Bartholomew, M.D.
and
Donald A. Scholz, M.D., Rochester, Minn.

• *Coma, hemiparesis, generalized convulsions, and other alarming neurological symptoms occurring postoperatively in five patients were shown to be associated with water intoxication and an unrecognized depletion of sodium. The diagnosis was verified by studies of the blood electrolytes and by the prompt clinical response to the intravenous administration of sodium chloride. The possibility of water intoxication and depletion of sodium should be considered in all patients in whom neurological disturbances develop during the first few days after operation.*

The possibility of water intoxication deserves serious consideration whenever acute neurological symptoms develop early in the postoperative period. Patients depleted of extracellular electrolytes are most susceptible to this disturbance in water balance. The widespread use of diets containing small amounts of sodium, alone or in conjunction with use of mercurial diuretics, frequently leads to depletion of the body's stores of sodium. The postoperative use of excessive amounts of nonelectrolytic solutions, principally a 5% solution of dextrose in water, in these or other patients who have experienced excessive preoperative loss of sodium chloride from the gastrointestinal tract may lead to unexpected and alarming neurological symptoms. The clinical signs and symptoms associated with mild degrees of water intoxication are nervousness, salivation, and vomiting. Disorientation, twitching of the extremities, stupor, convulsions, and coma have been noted in the more severe degrees of water intoxication. The clinical signs and symptoms usually associated with severe deficiency of sodium itself are primarily those of peripheral vascular collapse, namely, hypotension, coldness of the extremities, and a rapid, thready pulse. Pronounced impairment in renal function may develop. We have encountered five patients in whom severe but completely reversible neurological signs and symptoms developed during the postoperative period after administration of relatively large amounts of a 5% solution of dextrose in water. Unsuspected preoperative deficiency of sodium was present in three of these patients.

Report of Cases

CASE 1.—A 70-year-old woman was seen at the Mayo Clinic in August, 1953. She complained of four severe attacks of abdominal pain in the previous 15 years. The history was extremely suggestive of recurrent biliary colic, but jaundice had not occurred. She was known to have had hypertension for 15 years but

---

denied having had any particular treatment for it. Examination showed that the blood pressure varied between 138 to 155 mm. Hg systolic and 70 to 78 mm. Hg diastolic. A grade 1 systolic murmur was heard best over the aortic region. The edge of the liver was palpable 2 to 3 cm. below the right costal margin. Results of urinalysis were normal. The value for hemoglobin, the erythrocyte and leukocyte counts, the erythrocyte sedimentation rate, the amounts of serum bilirubin and lipase, and the results of a test of hepatic function with sulfobromophthalein sodium were normal. Roentgenographic examination of the skull revealed calcification of the falx and of the internal carotid arteries in the region of the sella. The gallbladder was not visualized roentgenographically. Fluoroscopic examination of the upper part of the intestinal tract disclosed a duodenal deformity. Cholecystectomy was advised. At operation, the gallbladder was found to be shrunken and densely adherent to the duodenum. When these two organs were separated, there appeared to be a cholecystoduodenal fistula. The gallbladder was removed in the usual manner. The pathological diagnosis was subacute ulcerative cholecystitis superimposed on chronic cholecystitis.

The postoperative course was uneventful until about the 34th hour. The patient then had a generalized convulsive seizure, with biting of the tongue, frothing at the mouth, and incontinence of urine. She became semicomatose a few minutes later. Babinski's sign was present bilaterally. The patient was aphasic within a few hours and had hemiparesis on the right. Review of the complete postoperative period revealed that the patient had passed approximately 1,300 ml. of urine and had received 5 liters of a 5% solution of dextrose in water. It was learned from her husband at this time that she had been following a fairly strict low-salt dietary regimen for the previous year. The possibility that her symptoms were secondary to water intoxication superimposed on depletion of sodium was then considered. Blood studies showed the following values: plasma chlorides, 85.7 mEq. per liter; urea, 14.0 mg. per 100 ml.; serum sodium, 112.0 mEq. per liter; and serum potassium, 3.0 mEq. per liter. Because of the longer time entailed in the determination of sodium and potassium, treatment in this and the other four cases was begun before values for these two constituents were available. A 5% solution of dextrose in isotonic sodium chloride was given. The patient gradually began to improve, and she fully regained consciousness. The concentration of serum sodium was normal for the first time on the seventh postoperative day, by which time the patient was able to talk, was well oriented, and had no evidence of hemiplegia. The remainder of the postoperative course was uneventful, and she was dismissed from the hospital on the 16th postoperative day.

Case 2.—A 72-year-old woman made her sixth visit to the clinic in September, 1953. She had been observed at various intervals since 1938. On her first visit, a diagnosis of duodenal ulcer and diffuse arteriolar disease with group 2 hypertension was made. In 1947, obstruction of the duodenum developed. Because of the patient's age and the hypertension, posterior gastroenterostomy was performed. In March, 1950, dysphagia developed, and a large pharyngoesophageal diverticulum was excised in one stage. Both surgical procedures were well tolerated, and the patient made uneventful recoveries. Later in 1950, hemiplegia on the left and aphasia developed. The defect in her speech gradually disappeared, although weakness in the left arm and leg persisted. In August, 1953, she noted the onset of epigastric burning distress and vomiting of the retention type. These symptoms continued for about six weeks prior to her return to the clinic. Examination revealed a blood pressure of 190/100 mm. Hg, hemiplegia with Babinski's sign on the left, and a loud succussion splash in the epigastrium. Results of routine urinalysis and hematological studies were normal. The blood urea was 46.0 mg. per 100 ml.; plasma chlorides measured 98.2 mEq. per liter; and the carbon dioxide-combining power was 33.0 mEq. per liter. Roentgenographic examination of the thorax revealed calcification of the aorta. Fluoroscopic studies of the upper part of the gastrointestinal tract showed a duodenal ulcer with obstruction and a nonfunctioning gastroenteric stoma. The patient was given a diet designed for use in gastric obstruction. Stomach lavage was done twice daily. The amount of gastric contents aspirated varied between 100 and 900 ml. On the 12th day in the hospital, an abdominal exploration was performed. The gastroenteric stoma was found to be malfunctioning because of the presence of an anastomotic ulcer. The duodenum was narrowed and almost completely obstructed. The operation consisted of partial gastrectomy and duodenectomy with an anterior Polya anastomosis.

On the day of operation, the patient received 500 ml. of blood, 2,100 ml. of a 5% solution of dextrose in water, and 1 liter of a 5% solution of dextrose in isotonic sodium chloride. On the second postoperative day, she received 4 liters of a 5% solution of dextrose in water. In addition, 400 ml. of fluid was obtained by means of gastric suction. She became drowsy and unresponsive approximately 30 hours after operation. In addition to the old hemiplegia on the left, there now appeared to be facial weakness on the right and increased spasticity of the right arm and leg. Babinski's sign was present on the right side. The initial clinical impression was that the patient had cerebral thrombosis on the left. However, in view of a possible fluid and electrolytic disturbance, blood studies were made. The value for blood urea was 24 mg. per 100 ml., and the plasma chlorides and carbon dioxide-combining power measured 66.0 and 23.0 mEq. per liter respectively; serum sodium and potassium measured 114.0 and 2.5 mEq. respectively. In the next 36 hours, a total of 6 liters of a 5% solution of dextrose in isotonic sodium chloride was administered intravenously. The patient's condition gradually began to improve, and she regained consciousness. The hemiparesis on the right disappeared, but the status of the old hemiplegia on the left remained unchanged. The patient was dismissed on the 13th postoperative day with no evidence of hemiparesis on the right.

Case 3.—An 80-year-old woman was seen at the clinic in December, 1954. She complained of anorexia and loss of 10 lb. (4.5 kg.) during the preceding year. She had noticed severe constipation alternating with diarrhea four weeks prior to admission. Examination revealed a hard fixed mass high in the rectum. Results of routine laboratory tests were within normal limits. Roentgenographic examination of the colon revealed almost complete obstruction in the lower portion of the sigmoid. Laparotomy was performed after suitable preparation of the intestine. The sigmoid was found to be the site of a perforating obstructive mass. The involved portion of the sigmoid was resected, and end-to-end anastomosis was accomplished. The pathological diagnosis was diverticulosis, diverticulitis, and peridiverticulitis. The postoperative course was uneventful for approximately 46 hours. The patient then became comatose. Generalized muscular twitchings were observed. Neurological examination revealed divergence of the eyes, transitory nystagmus, failure to move the left arm and left leg after noxious stimuli, generalized tendon hyporeflexia, and Babinski's sign in the left foot.

Since operation, the patient had passed approximately 2,000 ml. of urine and had received 5 liters of a 5% solution of dextrose in water. It was then learned from the family that she had been avoiding the use of salt in her diet for at least six months. The possibility of water intoxication superimposed on depletion of sodium was then considered. Blood studies revealed the following values: plasma chlorides, 66.0 mEq. per liter; carbon dioxide-combining power, 17.5 mEq. per liter; urea, 16.0 mg. per 100 ml.; and serum sodium and potassium, 105.0 and 2.2 mEq. per liter respectively. A total of 300 ml. of a 5% sodium chloride solution was then given intravenously. One hour later, the patient began to move all four extremities. In the second hour, she regained consciousness and responded to her name. Three hours after the onset of treatment, all the neurological signs had disappeared except Babinski's sign. Results of neurological examination were completely normal on the following morning. Intravenous administration of isotonic sodium chloride solution was continued during the next few days. Potassium chloride also was given intravenously. Improvement was maintained, and she was dismissed on the 17th postoperative day, at which time the blood electrolyte values were normal.

Case 4.—A 50-year-old woman registered at the clinic in August, 1955, complaining of periodic discharge from the left nipple. She had undergone cholecystectomy for gallstones in 1952. An incidental finding at the time of operation was a 3-cm. mass in the anterior wall of the stomach. Subtotal gastrectomy also was performed. Pathological examination showed carcinoma of the stomach without evidence of local metastasis. Subsequent examinations failed to reveal any evidence of recurrence of the tumor. The only abnormal finding on general examination at the clinic was discharge from the left nipple. Results of routine laboratory studies and roentgenography of the thorax were within normal limits. Fluoroscopic studies of the stomach revealed a high gastric resection with a freely functioning Polya type of anastomosis. The clinical impression was an intraductal papilloma of the left breast. Simple mastectomy was advised. The surgical findings confirmed the clinical diagnosis. The postoperative course was uneventful for approximately 36 hours. The patient then became semicomatose. Neurological examination revealed generalized tendon hyporeflexia, deviation of the eyes to the left, and Babinski's sign in the left foot. She became increasingly unresponsive during the next eight hours.

Review of the postoperative period disclosed that the patient had passed approximately 1 liter of urine and had had a total emesis of about 500 ml. During this time, she had received 6 liters of a 5% solution of dextrose in water. No history of restriction of salt or excessive loss of sodium could be obtained. In view of our previous experiences, the possibility of water intoxication was considered. Blood studies revealed the following values: plasma chlorides, 81.0 mEq. per liter; carbon dioxide-combining power, 18.0 mEq. per liter; urea, 15.0 mg. per 100 ml.; and serum sodium and serum potassium, 111.0 and 3.3 mEq. per liter respectively. One liter of isotonic sodium chloride solution was given intravenously. The patient began to improve and within a few hours regained consciousness. A total of 300 ml. of a 5% sodium chloride solution was then administered intravenously, followed by a liter of isotonic sodium chloride containing potassium chloride. Steady clinical improvement was maintained, and results of neurological examination were completely normal within 36 hours. Associated with this clinical improvement was pronounced diuresis. The patient was dismissed on the 10th postoperative day, at which time the blood electrolyte values were normal. An electroencephalogram taken during the period of unconsciousness showed grade 3 dysrhythmia, with no evidence of a focal organic process. The type of changes noted suggested the possibility of a metabolic disorder. Two days later, the electroencephalogram had returned to normal.

TABLE 1.—*Postoperative Neurological Disturbances in Five Patients with Water Intoxication*

Case	Sex and Age, Yr.	Preoperative Depletion of Sodium	Operation	Postoperative Neurological Disturbances	Fluids Given Postoperatively *Prior to* Neurological Disturbances	Immediate Treatment For Neurological Disturbances
1	F 70	Low-sodium diet, 1 yr.	Cholecystectomy	Generalized convulsion, coma, and hemiplegia on right, 34 hr. postoperatively	5 liters of 5D/W*	3 liters of 5D/S† in 36 hr.
2	F 72	Gastric obstruction and vomiting	Subtotal gastrectomy	Semicomatose with hemiplegia on right, 30 hr. postoperatively	500 ml. of whole blood; 6 liters of 5D/W; 1 liter of 5D/S	6 liters of 5D/S in 36 hr.
3	F 80	Low-sodium diet 6 mo.	Primary resection of sigmoid	Muscle twitchings, coma, and hemiparesis on left, 46 hr. postoperatively	5 liters of 5D/W	300 ml. of a 5% sodium chloride solution in 4 hr.; then isotonic sodium chloride
4	F 50	None	Simple mastectomy	Deep coma, 48 hr. postoperatively	6 liters of 5D/W	1 liter of isotonic sodium chloride followed by 300 ml. of 5% sodium chloride in 24 hr.; 1 liter of isotonic sodium chloride later
5	M 73	None	Cholecystectomy	Generalized convulsion, semicomatose, 6 days postoperatively	11 liters of 5D/W; 4 liters of 5D/S; 2.5 liters of fluids orally	2 liters of 5D/S in 24 hr.

* 5D/W=5% solution of dextrose in water. † 5D/S=5% solution of dextrose in isotonic sodium chloride.

CASE 5.—A 73-year-old man registered at the clinic in August, 1955. During the previous four months he had noted four attacks of epigastric and low substernal pain radiating to the left arm. These were associated with nausea and occasionally required an injection of meperidine (Demerol) hydrochloride for relief. Results of general examination and routine laboratory studies were completely negative. Electrocardiography and an exercise-tolerance test gave no objective evidence of coronary insufficiency. Roentgenograms of the gallbladder revealed cholelithiasis. Atypical gallbladder colic was considered to be the cause of his symtoms, and cholecystectomy was recommended. At operation, the gallbladder was distended and contained multiple stones. The gallbladder was removed in the usual manner. Further exploration of the abdomen revealed nothing of significance. The pathological diagnosis was chronic cholecystitis with multiple stones.

The postoperative course was not remarkable until the fifth day, at which time the patient complained of abdominal pain; later, the abdomen became moderately distended. It became necessary to institute gastric suction and to administer fluids parenterally. Generalized convulsions suddenly developed on the sixth postoperative day, with frothing at the mouth, stertorous respiration, and incontinence of feces. Neurological examination revealed lateral nystagmus and rigidity of all extremities. Babinski's sign was not present. A period of confusion followed the convulsive seizure. Review of the entire postoperative period revealed that the patient had received 11.0 liters of a 5% solution of dextrose in water, 4.0 liters of a 5% solution of dextrose in sodium chloride solution, and approximately 2.5 liters of fluids given orally. During this same period, a total of 1,800 ml. had been lost by emesis or gastric suction. The excretion of urine had averaged about 1 liter daily. The possibility of water intoxication was considered. Blood studies revealed the following values: plasma chlorides, 92.0 mEq. per liter; carbon dioxide-combining power, 21.0 mEq. per liter; urea, 26.0 mg. per 100 ml.; and serum sodium and serum potassium, 124.0 and 2.7 mEq. per liter respectively. Replacement therapy was started with a solution of 5% dextrose in isotonic sodium chloride, to which potassium was added. The patient's condition steadily improved. Within 24 to 36 hours the patient felt essentially normal and was able to take the necessary fluids orally. The blood electrolyte values rapidly returned to normal. Later studies, including a roentgenogram of the skull and an electroencephalogram, gave normal findings.

Comment

Some of the clinical and therapeutic data in our five cases are summarized in table 1. Four of the five patients were women. All the patients were in the older age group, which agrees with the usual age incidence noted in previous reports on water intoxication. The onset of neurological symptoms occurred within 48 hours after operation in four of the cases. Zimmermann and Wangensteen[1] have stressed that most seizures attributed to water intoxication tend to occur within the first 48 hours after operation. Definite predisposing factors for deficiency of sodium chloride were present in three of our five patients, namely, prolonged preoperative periods of deprivation of salt in two patients and excessive loss of electrolytes from the gastrointestinal tract in one patient. The low values for serum sodium, serum potassium, and plasma chlorides, along with the normal values for blood urea, were the most significant laboratory findings (table 2). This is in keeping with the experiences of Wynn and Rob,[2] as well as of Zimmermann and Wangensteen, who showed that the symptoms of water intoxication developed in most patients when the serum sodium value was reduced to less than 120 mEq. per liter. In the 17 cases reported by Zimmermann and Wangensteen, most of the values for sodium were less than 120 mEq. per liter and three were less than 110 mEq. It would appear that hyponatremia was a far more significant factor in the genesis of the neurological complications than was hypokalemia, since clinical improvement was noted in all of our cases after the intravenous administration of isotonic or concentrated sodium chloride solution without the addition of potassium. Wynn and Rob have reported similar experiences in which the symptoms of water intoxication responded dramatically to treatment despite the fact that coincident depletion of serum potassium was unchanged or became worse because potassium was not given. However, when it becomes known that a deficiency of potassium exists, potassium salts should be administered by either the oral or the parenteral route. The possibility that these neurological symptoms might be related to postinfusion hypoglycemia[3] deserves mention. This would appear to be completely excluded in four of our five patients, since they were receiving dextrose in water intravenously at the onset of symptoms.

TABLE 2.—*Values for Blood Electrolytes at Onset of Neurological Symptoms in Five Cases*

	mEq./Liter				
Case No.	Sodium	Potassium	Chlorides	Carbon Dioxide—Combining Power	Urea, Mg./100 Ml.
1	112	3.0	85.7	...	14
2	114	2.5	66.0	23.0	24
3	105	2.2	66.0	17.5	16
4	111	3.3	81.0	18.0	15
5	124	2.7	92.0	21.0	26
Normal values	135-145	4-5	97-106	25-29	10-40

Treatment.—The postoperative neurological complications in our patients were dramatic. Definite neurological signs of hemiparesis were present in two patients, while one patient had generalized convulsions associated with signs of hemiplegia. One patient had a generalized convulsive seizure, and the fifth patient became deeply comatose. The initial clinical impression in patients who had hemiplegia was an acute focal cerebral ischemia on the basis of either cerebral thrombosis or hemorrhage. When the diagnosis of water intoxication associated with possible deficiency of sodium was considered and the proper therapy was instituted, the clinical response of the patients was most gratifying. As stressed by Moore,[4] the treatment of mild water intoxication or dilution of sodium is first to limit the intake of water. The patient should be given no water whatsoever for 24 hours, and intravenous infusions should not be given until adequate laboratory studies can be carried out. In cases of severe degree, the careful and judicious administration of hypertonic solutions of sodium chloride is usually effective in correcting symptoms. In a mixed disturbance of deficiency of sodium with superimposed water intoxication, small infusions of hypertonic sodium chloride, such as 300 ml. of a 3 to 5% concentration, usually restore the extracellular compartment toward normal tonicity and thereby cause a shift of water from the cells. Hypertonic sodium chloride solution was administered with prompt results in two of our patients. On theoretical grounds, Wynn and Rob stressed the relative ineffectiveness and potential danger of treating water intoxication with infusions of isotonic sodium chloride. They considered that use of isotonic sodium chloride increases the volume of extracellular fluid and fails to increase the value of plasma sodium significantly, with resultant failure to relieve the overhydration of the cells. Nevertheless, administration of isotonic sodium chloride solution to three of our patients led to dramatic improvement and ultimate disappearance of the neurological symptoms. In the face of a decrease in serum sodium value, isotonic sodium chloride is in reality a hypertonic solution and, therefore, serves to increase the effective osmotic pressure of the plasma sufficiently to relieve intracellular edema. Coincident improvement in renal function and a diuretic response could be expected with increase of the level of serum sodium. However, we are in full agreement that treatment with hypertonic sodium chloride solution is the most effective and safest method when a definite diagnosis of acute water intoxication can be made on the basis of clinical observations and confirmatory laboratory data.

Predisposing Circumstances.—Certain circumstances predispose the patient to the development of water intoxication. A low intake of salt during the preoperative period may abet the development of water intoxication. McCance[5] has shown that extremely low concentrations of serum sodium can be produced by depletion of sodium without depletion of water only when the loss of sodium has been large. It has been recognized for years that the values of serum sodium and chloride regularly decrease from preoperative levels during the first 24 hours after operation.[1] The exact mechanism for the depression of these major extracellular electrolytes remains to be explained, although the function of the adrenal cortex ultimately may be proved to play an important role. Diminution of serum sodium also may produce a decrease in glomerular filtration and the diuretic responses to a water load. Preexisting renal insufficiency may play an important part in postoperative disturbances of water and electrolytic control. Cerebral arteriosclerosis with impaired circulation might predispose older persons to the development of the neurological symptoms of water intoxication.

Clinical Significance.—Weir and associates,[6] in 1922, were among the first to report the clinical significance of water intoxication. They were able to produce neurological symptoms in a patient who had diabetes insipidus by continuing the excessive intake of water after treatment with posterior pituitary extract. They also produced convulsive seizures in dogs by forced intake of water. McQuarrie,[7] in 1933, stressed the importance of electrolytes and water in the causation of convulsive seizures. It had been known for many years that dehydration and ketogenic diets aided in the control of epileptic seizures. In a series of clinical studies, McQuarrie concluded that brain cells are oversensitive to dilution of extracellular fluids. Alterations in the permeability of cellular membranes associated with a shift of water and electrolytes are probably fundamental in the production of convulsions. Adams and associates[8] utilizing radioactive sodium in studies in which cocaine was used to produce convulsions noted a shift of water from the extracellular fluid into brain cells. They also expressed the opinion that this was an important part of the extremely complex mechanism involved in the production of convulsions. Ariel[9] observed 20 patients before and after operation to determine the effect of the administration of electrolyte-free infusions. He used only a 5% solution of dextrose in water and found that all patients retained a portion of the water. This retention of water, although transient, was quite pronounced in a few instances. Convulsive seizures without any localizing signs developed in three of Ariel's patients.

Preoperative medication, anesthesia, and surgical procedures decrease the body's capacity to secrete water. Talbot and co-workers[10] have shown that simple solutions of dextrose are likely to produce water intoxication in anyone if given more rapidly than at a rate of 3 liters per square meter of body surface area per 24 hours. When patients are given morphine or one of its derivatives, or barbiturates, the tolerance to a simple solution of dextrose may be reduced to slightly more than 1 liter per square meter per 24 hours. The addition of as little as 40 mEq. of total base per liter of dextrose solution greatly increases tolerance. Thus, it is apparent that water intoxication can be prevented by careful consideration and supervision of the postoperative administration of fluids. It might be asked hether these patients actually had cerebral throm- s or hemorrhage in addition to water intoxication. nis question deserves consideration, but the subsequent course of events, namely, complete recovery of the patients in a relatively short period merely by the restoration of normal extracellular tonicity, would militate against this diagnosis.

Summary

A study has been made at the Mayo Clinic of five cases in which overt neurological signs and symptoms associated with water intoxication and an unrecognized depletion of sodium developed during the immediate postoperative period. The pronounced improvement and the disappearance of neurological symptoms after administration of isotonic or concentrated solutions of sodium chloride produced a dramatic clinical response. The possibility of water intoxication and concomitant depletion of sodium should be considered in all patients in whom hemiplegia, convulsions, or coma develops during the postoperative period.

THE ROLE OF REHABILITATION IN A PROGRAM FOR HANDICAPPED CHILDREN

Helen M. Wallace, M.D., Jerome S. Tobis, M.D., Robert S. Siffert, M.D., Margaret A. Losty, R.N.
and
Caroline H. Elledge, M.S.W., New York

- *Chronic disease is as important and rehabilitative programs are as necessary in children as they are in adults. There is reason to fear that children have sometimes been kept in institutions too long. The development of departments of physical medicine and rehabilitation, the use of consultants in this field, the multidisciplined approach, the integration of programs for children with those already existing for adults, and the facilities provided by recent federal legislation are significant steps toward the solution of this problem.*

By and large, rehabilitation of the chronically ill has been most closely identified with the care of the adult. Younger persons with chronic illness, although a frequent subject for special types of care, have not generally been included in programs of rehabilitation. The advances made in the field of rehabilitation of the adult during recent years, partly as a result of the impetus of World War II experiences, are equally applicable to the handicapped child. In the broadest sense, rehabilitation is the process by which the patient may attain the maximum physical, psychological, social, educational, and vocational restoration in the community.

Recognition of the importance of rehabilitation in the care of patients with chronic illness has recently

Professor of Preventive Medicine and Public Health, New York Medical College (Dr. Wallace); Chief Medical Social Work Consultant, New York City Department of Health (Mrs. Elledge); Consultant in Physical Medicine and Rehabilitation (Dr. Tobis), Senior Orthopedic Consultant (Dr. Siffert), Coordinator, Hospital Consultation Program (Miss Losty), and formerly Director (Dr. Wallace), Bureau for Handicapped Children, New York City Department of Health.

Read before the Maternal and Child Health Section at the Annual Meeting of the American Public Health Association, Kansas City, Mo., Nov. 15, 1955.

occurred through the extension of two important pieces of federal legislation—the Hill-Burton Act and the Vocational Rehabilitation Act. The anticipated end-result of the extension of these two federal legislative acts will be the opportunity to provide well-constructed and well-equipped physical resources and to provide the many persons with professional skills necessary for the management, care, and rehabilitation of the patient's physical, vocational, social, educational, and psychological needs. Particularly because of these two acts, with their potential influence on patient care, personnel engaged in crippled children's programs have a unique opportunity to improve services for handicapped children. Perhaps the first question that comes to mind is: How can these newer concepts of rehabilitation be used and applied for the benefits of handicapped children? While the details may vary from community to community, depending on present local resources of personnel and physical facilities, certain principles can probably be laid down.

Employment of a Consultant

Just as it is important to have expert medical consultants, such as the orthopedist, ophthalmologist, and otologist, for each of the specialties involved in a handicapped children's program, it is important to employ a consultant in physical medicine and rehabilitation to outline and coordinate more modern concepts of rehabilitation. His role might include (1) evaluation of the physical medicine and rehabilitation services; (2) assistance in the development of physical medicine and rehabilitation services; (3) assistance in the development of standards for a department of physical medicine and rehabilitation in institutions; and (4) assistance in the training of personnel on the staffs of health departments, crippled children's agencies, and institutions in rehabilitation methods and techniques.

In New York City the handicapped children's program has employed such a consultant for the past two years. He has played a large role in educating the handicapped children's team in rehabilitation methods. He has evaluated departments of physical medicine and rehabilitation at the hospitals surveyed, he has consulted on special problems arising in the program in relation to physical medicine and rehabilitation, and he has participated in training programs and in hospital conferences in interpreting concepts of rehabilitation as they relate to the practical care of handicapped children. As rehabilitation becomes a larger part of the program, his role will increase. In fact, specialists in physical medicine and rehabilitation have been regular members of the orthopedic advisory committee to help the program in development and evaluation of these aspects of total care.

For example, in New York City, a recent survey of 24 hospitals caring for orthopedically handicapped children disclosed that 14 had a department of physical medicine and rehabilitation. Of the 14 hospitals with a department of physical medicine and rehabilitation, 8 were found to be well organized and equipped. Seven hospitals had a separate rehabilitation inpatient service, and eight had a separate outpatient service. In nine hospitals, the physical medicine and rehabilitation department staff had periodic staff conferences. Twenty-two of the 24 hospitals had at least one physical therapist, but 10 had no occupational therapist, 10 had no speech therapist. 8 had no psychologist, 6 had no teacher, and 21 had no recreation worker. In nine hospitals, medical rounds were made by a physiatrist; the visits varied in frequency from "daily" to "rarely." In 15 hospitals, no such rounds were made. It seems evident from this survey material that there is wide variation in the quality and quantity of physical medicine and rehabilitation services afforded orthopedically handicapped children. One of the major functions of the consulting physiatrist to the department of health has been to work with the hospitals to assist them with the further development of their services.

Rehabilitation Training Program

As in any new field, there is a certain body of knowledge developed and there are certain techniques used that may be helpful and that, therefore, should be disseminated to professional personnel working with patients. This is true for rehabilitation. and it applies equally well both to the staffs of institutions and to the staffs of crippled children's agencies and health departments. For example, from reports based on surveys of hospitals and convalescent homes in the metropolitan New York City area, children are being kept in institutions too long, and, in general, the program for children has not been one of active rehabilitation. Perhaps with the newer knowledge of rehabilitation techniques and the teaching of activities of daily living. such as feeding, dressing, toilet care, bowel and bladder control training, wheel chair transfer, ambulation, and gait training, these programs can become much more dynamic and positive for patient care. This same principle should be equally applied to patients at home who are visited by public health nurses, with the specific purpose of assisting the patient to develop maximum self-sufficiency wherever he is. Such a rehabilitation training program should, in our opinion, be developed on a multidisciplined team basis, for both the faculty and the trainees. One tangible plan might be that each health jurisdiction have at least one person, possibly a physician or public health nurse, who had had special training in the field and who would be the resource staff person for improvement in patient care in the specific field.

The field of physical medicine and rehabilitation is a new medical specialty that concerns itself with the care of children with neuromuscular and musculoskeletal disorders. This medical specialty, as does medicine generally, in the care of the chronically ill, provides symptomatic treatment directed toward improving the function of the patient without influencing the underlying disease process. Thus it seeks to improve motor power whether the weakness results from a lower motor neuron disease, such as poliomyelitis, or an upper motor neuron disease, such as intracranial damage. In this field disease is looked upon as more than the specific pathology and the social and psychological effects of the disability upon the total function of the patient are considered. Because all these factors and more must be considered in the total care of the patient, there are many disciplines involved in the rehabilitation of the handicapped child. The professional staff, including such specialists as the pediatrician, orthopedist, psychiatrist, ophthalmologist, neurologist, physical therapist, occupational therapist, psychologist, speech therapist, vocational or educational counselor, social worker, and nurse, functions as a team under the direction of the physiatrist. There is one additional unnamed member of the team whose participation is essential—the patient himself. By the very nature of rehabilitation care, the patient must be an active participant. In medical care of acute conditions, the success of treatment does not depend essentially upon the cooperation of the patient. If a child has pneumonia, the outcome will depend upon the diagnostic acumen of the physician, the efficacy of the antibiotic prescribed, and the nursing care given, not on whether the child is cooperative. But in rehabilitation, the success of treatment requires the active participation of the child because of two major factors: 1. Rehabilitation is primarily a learning or relearning process on the part of the patient—the learning of new and greater skills. 2. The necessary increase of motor power is dependent upon active exercises that the patient himself must perform.

Multidisciplined Approach

Rehabilitation of many handicapped children and adults usually requires a battery of skills as well as a large number of medical specialists in addition to the patient himself and his family. To produce a truly effective program that will result in the rehabilitation of the patient, these skilled persons must have an understanding of the contribution and role of each of the other professional groups and must be able to work closely together in order to provide the services the patient needs when he needs them. The multidisciplined approach should result not in a replacement of one type of professional worker by another but rather in a supplementation of one by the other. This should apply to the stage of the initial evaluation of the patient, periodic reevaluations, continuous supervision, and counseling of the patient and his family.

The paramedical members of this team have many roles, each of which complements the other. The physical therapist improves the patient's motor power by exercise, teaches ambulation, and applies physical modalities to relieve pain, reduce inflammation, and increase range of motion. The occupational therapist improves the dexterity and power of the patient's upper extremities by giving him meaningful work. She also teaches the patient self-care techniques, such as feeding and dressing himself. The rehabilitation nurse complements the role of the occupational therapist by continuing the self-care activities on the ward. The educational or vocational counselor evaluates the child's educational or vocational capacities and aptitudes and aids in the plans for his future training and study. The psychologist evaluates the child's intellectual and emotional profile and assists other therapists in creating the optimum conditions for the patient's learning of new techniques of rehabilitation. The speech therapist assists the child with speech and language disorders in order to help him attain his maximum potential. The social worker relates the family and home situation in the treatment planning. The group worker applies recreation programing as a physical and social therapeutic activity for the child. The teacher contributes to the over-all evaluation and educational goals of the child.

Integration with Adult Programs

Because of the country's aging population, chronic illness has become one of the major public health problems, and health departments are now planning and developing rehabilitation programs and services for adults with chronic illness. By and large, however, chronic illness does not magically begin at the age of 21 years. Many principles learned in the rehabilitation of handicapped children are equally applicable to adults, and many services developed for one age group can be and should be utilized and modified for the rehabilitation of the other age group. Services for the rehabilitation of handicapped children and adults must be coordinated and integrated. The artificial separation of the under 21 and over 21 age groups merely confuses community planning and results in duplication of efforts, funds, and services. Failure to apply the knowledge gained in one age group to the other age group causes repetition of errors in the trial-and-error method. It is important, therefore, that there be close integration of chronic disease rehabilitation programs and services for both children and adults.

Consideration of Long-Term Care

Rehabilitation of the handicapped child is frequently not accomplished on a short-term basis. As is true of any chronically ill patient, child or adult, long-term care is often essential. Frequently long-term care has meant for the child, at least, long-term institutional care. It should more properly imply the necessity of continuity of care, supervision, and rehabilitation wherever the child is—in an inpatient service, in an outpatient department, at home, in school, in job-training, or at camp. This principle of continuity of long-term care must include provision of the multidisciplined team in the various settings listed above as well as provision for flexibility for the easy flow of patients, when they are ready, from one setting to another and provision for the rapid interchange of full information from one setting to another. Otherwise, it is possible and probable that some patients will become fixed in one setting, which may be appropriate at one time but inappropriate at another time. It is also true that lack of interchange of information usually results in the expenditure of efforts and funds for duplicating evaluations. This may be discouraging to the patient and his family as well as being wasteful of the community's resources.

Evaluation of Results and Development of Priorities and Standards

The principle of evaluation of results is important for the individual patient, for the administrator of a crippled children's program, and for the director of any community service in future planning. Studies are necessary to develop even such basic data as the rehabilitation results in the individual patient for a given period of time, the most effective and successful techniques in certain types of disabilities, and the cost of rehabilitation per patient for each diagnostic group by individual institutions. Other such necessary studies include the duration of inpatient care and the reasons for prolonged inpatient stay; long-term longitudinal studies of the handicapped, comparing results in those who have had the opportunity for comprehensive rehabilitation care with those who have not; the results of prolonged inpatient care compared with an alternate community method, such as an organized home care program; the reasons for vocational success and failure among the handicapped in order to provide leads for further development of community services; and retrospective studies of adults who have been handicapped by conditions arising in infancy and childhood and who are now receiving public assistance. Such studies are essential if medical advances are to be made in improvement of methods and if fiscal authorities and the public are to be convinced of the value of rehabilitation programs.

In the early stages of any rehabilitation program, priorities must be established, since there are usually insufficient personnel and funds to serve all patients. The development of a priority system may be carried out on the basis of diagnosis or degree of disability. A priority list developed for one community will not necessarily be applicable in all phases to another community. The community's existing resources, available personnel, and public and professional interests are key factors in deciding any priority system. Also, carefully worked out standards are essential to serve as guides to participating institutions and agencies in their planning and developing good services. They will also be of help to accrediting groups in approving adequate acceptable services for a payment program.

Development of Community Services and Resources

In the development of community services and resources, a fairly complete knowledge of existing services and resources and of current gaps or lacks in patient care is necessary. This quantitive and qualitative knowledge should include such details as the hospitals and convalescent homes; the resources for the homebound group of children; the services provided for the children.,at school, especially the high priority groups in special classes or schools; the vocational resources, including sheltered workshops; the recreational programs; the transportation facilities; the long-term residential or custodial services; and the foster home and child welfare services. It is likely that in most communities at the present time "pieces" of services are now available and that undoubtedly there are many good or potentially good resources that can be further developed and improved with guidance, financial support, consultation, and patience.

Two examples will be used to illustrate this principle: the hospital resources and the convalescent resources. Once a knowledge of the hospital resources has been acquired, it is likely that it will be found that a minority of the hospitals have active and well-developed rehabilitation programs. The principles that might apply in such a situation are as follows: 1. General and not specialty hospitals would participate in the program in the beginning. 2. The initial selection would be of those hospitals that serve a teaching function in connection with medical and other professional schools, from the viewpoints of patient care, training of personnel, and research. 3. Diagnostic services on the one hand would be integrated with treatment and rehabilitation services on the other hand; this step might mean either the affiliation and joint staffing of detached diagnostic clinic services with hospitals or the physical relocation of detached diagnostic clinic services in hospitals with joint staffing. 4. There would be the development of a generalized rehabilitation program within the hospital. This program ideally would not be a completely separate one but would be one that would be closely integrated with other clinical departments so that rehabilitation techniques could be applied early; such a principle would apply to both inpatient and outpatient care. 5. There would be the development of certain specialized services in the hospital; for example, services for patients with hearing impairment, cleft palate, convulsive disorder, and mental retardation as well as for the traditionally accepted groups of patients, such as those with orthopedic, cardiac, and visual defects. 6. Assistance and guidance would be given to the hospitals in the recruitment of personnel, the training of personnel, and the development of program policies. 7. There would be continuity of care, including supervision and follow-up, between the hospital inpatient service and outpatient service and the home through the development of broad home care programs or the more limited public health nursing referral and follow-up.

The second example selected—that of convalescent care in the traditional convalescent homes—is more controversial and therefore more interesting. Once a working knowledge of the community's convalescent homes has been acquired, several principles might apply and a number of questions might be raised, such as: Is convalescent care as it has been traditionally given in the past necessary at the present time? What kinds of children are presently in convalescent homes, what are the reasons that they are there, and how many can be discharged home? Is a particular convalescent home fulfilling an essential community need at this time? Can a dynamic and active rehabilitation program be provided in a convalescent home currently located in a semirural setting, with its difficulties of recruitment and retaining of well-trained personnel, of close medical supervision, and of parent visiting? What are the alternatives that a community might provide that might mean better and more prompt rehabilitation care, better psychological care, and possibly even lower cost to the community? What are the current facts about the present capacity, census, and length of stay in convalescent homes? The first essential principle that should apply to this somewhat controversial subject, in an effort to answer the foregoing questions, is that of fact-finding. Other principles, which undoubtedly fall into the general area of better coordinated and broader community planning of rehabilitation services, will stem from the original one of *fact-finding*.

Relationship to Newer Federal Legislation

Two types of federal legislation were extended recently that are of great significance to programs for handicapped children: (1) the Hill-Burton Act, which will make available new funds for construction and equipping of rehabilitation centers, diagnostic centers, chronic disease services, and nursing homes, in addition to the funds presently appropriated for general hospital construction; and (2) the Vocational Rehabilitation Act, which will make funds available for special projects, training of personnel, and research. It would seem essential that administrators and clinicians concerned with the program for handicapped children work closely with the state and local agencies responsible for the carrying out of new federal legislation because (1) personnel engaged in crippled children's programs already may have considerable knowledge about services and facilities currently provided and about unmet needs and (2) the new federal legislation provides a means of improving and expanding services for handicapped children. Joint planning is essential if the newly provided funds are to be used in the soundest way for the maximum number of people to be served. It would seem, too, that the crippled children's agency might provide the methods or means of bringing together the medical and health treatment agencies and the vocational agencies in any community. Up to the present time, in some communities, these two groups have not worked as closely together as they might, with a result usually to the detriment of disabled patients. On the one hand, some medical treatment agencies know of and render medical and health services to large numbers of patients without significant awareness of their vocational needs and without early referral for vocational guidance, testing, training, and placement. On the other hand, some vocational agencies are currently in the position of offering vocational assistance without adequate knowledge of the medical status and functional ability of the individual patient. Liaison between these two types of community agencies is essential, and a crippled children's program might serve in such a coordinating capacity.

Purchase of Care

Rehabilitation of patients is costly; for example, the per diem cost of inpatient care in a large rehabilitation service in New York City is $25 for a child and $30 for an adult. Even though there is a considerable amount of funds available for the rehabilitation of patients, from both official and voluntary sources, funds will always be wanting. These two sources of funds, official and voluntary, should not be looked upon as competitors of each other; both are essential. This principle can work in a variety of ways, such as by grants to agencies or services, complete payment of salaries, joint payment of salaries, purchase of equipment, research projects and experimentation, and training of personnel. The important principle is that the two major sources of funds work together to develop rehabilitation services as rapidly as possible with well-trained personnel wherever they are needed. *The second principle is that of the purchase of care on a cost basis.* If one accepts the fact that rehabilitation is economically sound as well as socially desirable even though it is costly, then someone must be prepared to pay the bill. Logical sources, in addition to the patient and his family, are the categorical voluntary agencies and governmental agencies, including the crippled children's program. It is a fallacy that by paying less than cost, if cost is calculated on a sound formula, one is saving money. If the cost of care is not met in some way, then services are automatically decreased by reduction of personnel. This means that some essential services will not be provided and that rehabilitation may not be as effective or as complete. In any event, by not meeting the costs of rehabilitation, it is the patient and the community who "pay the price"; and the principle of purchase of care on a cost basis is a vital one.

Summary

Some principles in the possible role of rehabilitation in services for handicapped children may be based on experience in a large crippled children's program in an urban area. These principles include the employment of a consultant in the field of physical medicine and rehabilitation as a staff member of the crippled children's agency, the need for the establishment of a training program in rehabilitation to disseminate the newer knowledge developed in the field to personnel working directly with patients, the use of the multidisciplined team approach to meet the broad needs of the patients, and the need to integrate rehabilitation services for children with those for adults. It is necessary to recognize the need for long-term follow-up and supervision of patients and for flexibility of services and policies. Evaluation of results of services to the individual patient is important, and methods for such evaluation must be devised. Additional principles are those of development of knowledge regarding present resources and currently unmet needs of patient care and purchase of care on a cost basis. Newer extensions of federal legislation, such as the Hill-Burton Act and the Vocational Rehabilitation Act, provide excellent opportunities to develop, expand, and improve services for patients with chronic illness, both children and adults.

CLINICAL NOTES

SERUM PROTEIN CHANGES IN SUBACUTE THYROIDITIS

Grant N. Stemmermann, M.D., Hilo, T. H.

Subacute thyroiditis is an inflammatory disease involving the thyroid gland but associated with a systemic reaction characterized by fever and general malaise. A large number of papers upon this subject have appeared within the last decade. Recently these have been summarized in a complete review undertaken by Hazard.[1] It is my purpose to describe a laboratory finding in this disease, mention of which I have not encountered in the medical literature available to me. This consists of a striking elevation of the alpha-2 component of the globulin fraction of the blood. I shall describe two cases in which this change was noted and shall attempt to explain the cause of this change, correlating it with other reported findings.

Report of Cases

CASE 1.—A 47-year-old Caucasian man first became ill on Sept. 1, 1955. His initial symptoms were general malaise and weakness after vigorous walking. He also had a low-grade afternoon fever (99.6 F [37.6 C]) followed by sweating. He also complained of a mild sore throat, which varied in intensity from time to time. Ten days later he developed a hard, tender mass at the lower anterior margin of the right sternomastoid muscle. He was admitted to hospital on Sept. 18, 1955. His medical history and family history contained no facts related to the present illness. Physical examination on admission revealed the tender mass in the area of the right lobe of the thyroid gland to have subsided and to have been replaced by a similar mass in the region of the isthmus.

Laboratory findings were as follows. Urinalysis was negative for sugar and albumin. The specific gravity was 1.020, with 3 white blood cells per high-power field. The nonprotein nitrogen level was 32 mg. per 100 cc., total protein level was 7.4 gm. per 100 cc., with albumin 4.8, globulin 2.6, and albumin-globulin ratio 1.85. The white blood cell count was 11,800 per cubic millimeter, with 69% neutrophils and 31% lymphocytes, hemoglobin level was 12.4 gm. per 100 cc. and hematocrit 42%. The erythrocyte sedimentation rate was 48 mm. in one hour. The serologic test for syphilis was nonreactive, and the cholesterol value was 157 mg. per 100 cc.

A needle biopsy of the thyroid tissue revealed the basic architecture to be considerably disturbed. The follicles were decreased in number and widely separated from one another by an edematous connective tissue. Within this tissue were many lymphocytes, plump fibroblasts, and collagen fibers. Within some of the follicles were collections of neutrophils. Others were partially bordered by epithelioid cells and Langhan's-type giant cells, forming a tuberculoid focus. Some of these collections enclosed small amounts of persisting colloid. This patient's symptoms abated spontaneously without specific therapy.

CASE 2.—A 40-year-old man of Japanese origin was well until early November, 1955, when he noticed that he had a fever. His temperature was 104 F (40 C). He received some unidentified medication from a physician, but there was no improvement in his febrile disease. His only symptom other than the fever was slight pain in the throat when this region was pressed. He denied having any cough, shortness of breath, nausea, or vomiting. His medical history and family history were of little interest insofar as the present disease was concerned. On physical examination he was found to have slight injection of the tonsillar area. He also had a slightly enlarged and tender right lobe of the thyroid gland.

The laboratory findings were as follows. The white blood cell count was 7,700 per cubic millimeter, with 66% neutrophils, 22% lymphocytes, 10% monocytes, and 2% eosinophils. The hemoglobin level was 14 gm. per 100 cc., and the hematocrit was 45%. The erythrocyte sedimentation rate was 32 mm. in one hour. The findings on urinalysis were specific gravity 1.016, albumin and sugar negative. No cells or casts were seen. Prothrombin time was 53% of normal. The total protein value was 8 gm. per 100 cc., with albumin 3.7, globulin 4.3, and albumin-globulin ratio 0.86. The serologic test for syphilis was nonreactive. Blood cultures were repeatedly negative, and heterophil agglutination was positive through 1:8 dilution.

A needle biopsy of the thyroid gland was done, and microscopic examination revealed many of the follicles to be distorted. Some contained mixed neutrophils, monocytes, and colloid. The lining epithelium of these follicles persisted, but there were others in which the process just described had progressed to the extent that no epithelium was any longer seen. In the latter areas the collections of neutrophils were surrounded by palisaded epithelioid cells. The interstitial connective tissue was increased in amount and contained collections of lymphocytes, monocytic cells, and neutrophils. This patient's signs and symptoms promptly abated under cortisone therapy.

Pathological Changes

The pathological changes noted within the glandular tissue were typical of those reported by other authors. A wide variety was noted in the appearance of the individual follicles. The earliest change consisted of the accumulation of a few neutrophils within the colloid. These elements were surrounded by persisting colloid, and the follicular epithelium remained intact. In other follicles the epithelium was replaced by dense masses of neutrophils and monocytic elements. Where this change was most intense, segments of the follicular basement membranes were destroyed. In other areas collections of colloid were surrounded by histiocytic elements and giant cells of the Langhan's type. The histiocytic cells had a palisaded arrangement. The interstitial connective tissue was edematous and increased in amount. It contained collections of lymphocytes, neutrophils, plasma cells, monocytes, occasional giant cells, and fibroblasts.

Laboratory Findings

There was a striking increase in the alpha-2 globulin fraction as seen by the paper electrophoresis method. This distortion of the protein pattern accompanied a normal albumin-globulin ratio in one case and an inverted one in the other. This reversal was due to an increase of the globulin fraction as a whole rather than the decrease in the albumin portion. Furthermore, there was an increase in both the beta and the gamma fractions as well, although the latter change was not so striking as that seen in the alpha-2 fraction. The alpha-2 fraction appeared to migrate in a slightly faster range than the normal alpha-2 fraction.

Comment

These findings are of particular interest when they are compared with other changes noted in this disease. It has been reported that during the active phase of the disease there is a strikingly negligible uptake of radioiodine (I^{131}) and a definitely elevated serum protein-bound iodine value.[2] It has been felt that the elevation of the protein-bound iodine level was the

---

From the Laboratory, Hilo Memorial Hospital result of follicular destruction and the absorption of colloid into the blood stream. This concept would seem to be confirmed by the change in the electrophoretic pattern of the blood proteins. A recent study by Shulman, Rose, and Witebsky[3] is pertinent in this regard. These workers studied the electrophoretic patterns of material obtained from hog thyroid glands. They noted that the thyroid extract revealed essentially a single component, moving with a mobility slightly greater than that of hog alpha-2 globulin. They felt that this component was thyroglobulin.

These findings are of both practical and academic interest. It has been said that the only laboratory tests of value in the diagnosis of subacute thyroiditis are the determinations of protein-bound iodine and the uptake of the thyroid gland of I^{131}. In communities where neither of these examinations is available due to space or budget limitations, the electrophoretic pattern, obtained with simple equipment, may indicate that this disease is present. This is an important factor in some cases that present themselves to the physician as a fever of unknown origin. In the second case mentioned in this study the tenderness in the thyroid gland was so slight that no biopsy would have been made of the gland if the protein changes had not been known. The test would not be specific, since in any condition allowing the escape of follicular contents into the bloodstream there might be expected to be a high alpha-2 globulin value. For instance, Flynn[4] reports an increase in the fraction in a case of carcinoma of the thyroid, but the absence of systemic complaints should allow differentiation from thyroiditis. Isolated alpha-2 globulin elevation may also be seen in the nephrotic syndrome, but the wide difference in clinical appearances between this disease and thyroiditis should permit no confusion. In addition, the elevated fraction in the renal disease migrates in a slower range than that seen in thyroiditis, sometimes appearing to blend with the beta fraction.

Summary

In two cases of subacute thyroiditis an elevation of the alpha-2 globulin fraction was noted by the paper electrophoretic technique. This change is felt to be due to escape of a colloid into the bloodstream as a result of structural distortion of the follicles.

Addendum

Since this paper was submitted for publication, two additional cases of thyroiditis have been seen in which the above protein changes were found to be present. One of these was of special interest because the changes were not present during a four-day prodromal period of fever but were only noted after the patient's thyroid became tender.

HYALURONIDASE AS AN ADJUVANT IN INSULIN SHOCK THERAPY

Milo Tyndel, M.D., Ph.D., Brandon, Manitoba, Canada

Extensive studies have been performed and reports published during the last few years concerning the biochemical, physiological, and therapeutic actions of hyaluronidase, the most important of the "spreading factors." Very few of these studies have been concerned with the use of hyaluronidase as an aid to insulin shock therapy with regard to decreasing the amount of insulin necessary, accelerating the evolution of comas and thus increasing the period of actual treatment, and avoiding its untoward effects, particularly the so-called after-shocks. Although the value of insulin shock therapy is still controversial, this therapy continues to be widely used in mental hospitals throughout the world for the management of schizophrenia and other psychiatric disorders. Therefore, every method leading to possible technical improvements in the administration of this therapy is welcome and should be given attention.

Reports on the use of hyaluronidase in insulin shock therapy have been published by Straccia and Scheflein,[1] Demay, Mises, Bories, and Chanoit,[2] Gysin and Wilson,[3] and Greenbank.[4] During my investigations, started at the Hospital for Mental Diseases in 1955, I confirmed the favorable reports of these authors and made some observations not published hitherto. Since I consider these observations useful for the routine application of insulin shock therapy, I shall briefly outline the findings.

Material and Method

In the investigations hyaluronidase was first used in dissolved form (Wydase). A milky turbidity was noticed when this was mixed with insulin. Since the supplier of the hyaluronidase notified me that the same turbidity has been observed with some types of insulin in other clinical investigations, I changed to the lyophilized form, which showed less tendency to cloud when mixed with insulin. However, it was found that the cloudiness did not have any significant untoward effect on either the insulin or the hyaluronidase. As to the dose of hyaluronidase added to the insulin, Gysin and Wilson found 75 turbidity-reducing units (T.R.U.) to be the most efficient. I tried to find the optimum dosage by adding from 25 to 150 T.R.U. Doses smaller than 75 T.R.U. appeared definitely insufficient to influence the structure of comatose reactions to insulin. Doses up to 150 T.R.U. did not seem to be more efficient than 100 T.R.U. I felt that 100 T.R.U. could be considered the optimum dosage, although the difference in action between 75 and 100 was not considerable. This optimum dosage was found irrespective of the amount of insulin administered. In my investigations I used lyophilized hyaluronidase in 10-cc. vials containing 1,500 T.R.U. I dissolved this powder in 15 cc. of isotonic sodium chloride solution, each cubic centimeter containing 100 T.R.U.

From the Hospital for Mental Diseases. Dr. Tyndel is now at Misericordia General Hospital, Winnipeg, Canada.

Results

No untoward local or systemic effects were noticed during the period of the investigation (five months). I administered hyaluronidase to 37 patients suffering from schizophrenia and other psychiatric conditions requiring either insulin shock therapy or modified insulin shock therapy. The number of hyaluronidase injections was about 1,000. As is usual in insulin shock therapy, the injections were given deeply intramuscularly. As controls for our investigations I used 13 patients who were given insulin shock therapy without hyaluronidase. The entire group of patients to whom hyaluronidase had been administered served as another control. By stopping the administration of hyaluronidase once for two days and much later for another four days I was able to observe the obvious differences regarding the depth of hypoglycemic reactions without having changed the dosage of insulin. Patients who had reached a coma level with hyaluronidase over many days of treatment dropped down to semicoma level immediately after withdrawal of hyaluronidase; other patients who had reached a semicoma level were able to take their feedings by mouth. The table gives a good picture of this difference.

Depth of Hypoglycemic Reactions

	Without Hyaluronidase	With 100 T.R.U.* of Hyaluronidase
Comatose	...	10
Semicomatose reactions	8	3
Oral feedings	5	...
Total	13	13

* T.R.U., turbidity-reducing units.

By the administration of hyaluronidase I was able to decrease the coma doses of insulin by a considerable amount. Before hyaluronidase, 7 of a group of 13 patients required doses higher than 300 units of insulin daily (up to 600). In the same group only three patients required doses higher than 300 units of insulin (up to 440 in one case only) when 25 to 75 T.R.U. of hyaluronidase were administered, and only one patient in the same group required doses higher than 300 units of insulin (up to 350) when 100 T.R.U. was administered. The average total dose of insulin administered on one of the insulin shock therapy wards in the hospital, calculated on the basis of the amounts received by 13 male patients over the first six months of 1955, was 4,400 units. After the routine administration of hyaluronidase, the average total dose of insulin on the same ward dropped to 2,200 units per week. Without hyaluronidase, the average coma dosage of insulin given to a group of 13 patients was 365 units; with hyaluronidase this dosage dropped to 212 units.

There are considerable variations in the decrease of insulin made possible by the administration of hyaluronidase; however, in my series I did not find any patient whose condition seemed completely refractory to hyaluronidase. In two patients who had had a course of insulin shock therapy on a previous occasion, the average dose of insulin required to obtain a coma level was 80 units with hyaluronidase as compared to 160 units during their former course. In two patients showing a marked tendency to spasticity and cyanosis with doses of 400 and 500 units without reaching a semicoma level, I was able to obtain semicomatose reactions with much greatly lessened degrees of spasticity and cyanosis at doses of 200 and 320 units respectively.

The average monthly number of comatose reactions in a group of 12 patients not receiving hyaluronidase was 77; with hyaluronidase this number was increased to 120. The time elapsing between the injection of insulin and the initial shock signs was shortened by about one-third (from an average of 100 minutes to about 70 minutes), thus increasing the duration of the semicoma. Taking the number of 50 reactions (including comatose, semicomatose, and convulsive responses) as the routine figure for a complete course of insulin shock therapy, without hyaluronidase the course used to require an average of 61 days of treatment. With the addition of hyaluronidase this period was reduced to an average of 55½ days.

In addition to the findings listed above, I would like to mention the following observations made during my investigations. During the early phases of shock there appeared to be a lesser tendency to hyperactivity and apprehension. The patients appeared quieter and showed less tendency to complications (e. g., respiratory difficulties) during both coma and semicoma levels and they appeared much less exhausted. The acceleration of the pulse rate appears considerably decreased when hyaluronidase is used. Whereas I used to notice pulse rates from between 100 to 140 per minute, the average pulse rate dropped to 90 to 100, and pulse rates over 100 were rarely found. With the use of hyaluronidase the average number of semicomatose and comatose reactions on Mondays, after the two-day weekend break, or after breaks for other reasons, showed a considerable increase. The decreased insulin dosage permits reduction of 1 oz. (30 cc.) of glucose for every 20 units of insulin. The average reduction of glucose feeding required per patient was 6 oz. (177 cc.) per day.

During the whole period of five months after the start of the investigation on hyaluronidase, there were no after-shocks in the afternoons and evenings of the treatment days. Without the use of hyaluronidase there were usually up to 4 out of a group of 13 patients who showed signs of after-shock on Mondays and 1 to 2 per day on the following four treatment days. Prior to use of hyaluronidase it had been my practice to give a feeding of 5 to 8 oz. (148 to 237 cc.) of glucose routinely at 1:30 p. m. After using hyaluronidase I discontinued this feeding without seeing any signs of after-shock. In a group of 13 patients the average reduction of glucose amounted to 100 to 120 oz. (2,957 to 3,549 cc.) per day.

It is felt that through the acceleration of metabolic changes due to the use of hyaluronidase the tendency to convulsions has decreased, although it is difficult to assess this finding with any accuracy. There were some noticeable changes in the patients' behavior and feelings during the afternoon and evening periods. The patients appeared more alert and less sluggish and apathetic. They were more active in participating in ward and hospital activities. They did not complain about feelings of fulness, and at the same time fewer patients were nauseated and vomited and therefore were better able to take noon meals and lunches without any persuasion.

Comment

Hyaluronidase has a definite action in reducing the resistance of tissues to diffusion and absorption of injected fluids. This applies also to insulin given intramuscularly for the shock therapy of schizophrenia and other psychiatric disorders. In my investigation about 1,000 injections of lyophilized hyaluronidase ranging from 25 to 150 T.R.U. were added to insulin in a group of 37 psychiatric patients. The addition of hyaluronidase to insulin has proved to be a valuable adjuvant to insulin shock therapy by (*a*) reducing the amount of insulin required to produce semicomatose and comatose reactions, (*b*) increasing the effective length of treatment levels, (*c*) eliminating the danger of after-shocks, (*d*) increasing the number of therapeutically valuable reactions, (*e*) decreasing untoward symptoms and signs due to feeding of glucose, (*f*) decreasing the tendency toward convulsions as well as toward restlessness and exhaustion, and (*g*) decreasing untoward strain on the vascular and respiratory systems. The optimal dose of hyaluronidase has been found to be 100 T.R.U., irrespective of the dose of insulin. No untoward local and systemic effects have been noticed. From an economic viewpoint, the savings in insulin and glucose as well as in days of treatment required for a full course of insulin shock therapy make up for the additional expense of the hyaluronidase.

Summary

Investigations carried out on 37 psychotic patients undergoing insulin shock therapy show that hyaluronidase (Wydase) is a valuable adjuvant to this treatment in improving its action and reducing its dangers and side-effects; it is also economical. The use of this modification of routine insulin shock therapy can be recommended safely.

John Wyeth and Brother (Canada) Limited supplied the hyaluronidase (Wydase) used in this study.

Anticoagulant Therapy.—An interrupted schedule of administering maintenance doses of warfarin sodium every third or fourth day has been tried and appears not to be satisfactory in view of the wide fluctuation of prothrombin levels. Administration of warfarin sodium guided by the day's prothrombin determination would seem to be the best method, and, if a pattern is established, the prothrombin determinations safely can be reduced in frequency. Individual dosage requirements vary widely, but for the majority, after an initial dose of 75 mg., daily or every-other-day doses of 12.5 mg. will satisfactorily maintain a proper hypoprothrombinemia.—D. V. Clatanoff, M.D., and O. O. Meyer, M.D., Further Observations on Use of Warfarin Sodium in Anticoagulant Therapy, A. M. A. *Archives of Internal Medicine*, June, 1956.

SPECIAL ARTICLE

DEFENSIVE ASPECTS OF BIOLOGICAL WARFARE

Arnold G. Wedum, M.D., Frederick, Md.

The offensive potential of biological warfare has created public health problems that were not known 10 years ago. For example, the vulnerability of the human respiratory tract as an avenue for infectious aerosols[1] dictates serious attention to the problems associated with the pathogenesis of diseases that can be produced by such means. It follows that the effectiveness of our antibiotics, vaccines, and toxoids will not be fully known until they are evaluated by respiratory challenge of animals or man. This is the most important thought that I wish to emphasize.

In the medical literature there are adequate reports of instances in which the number of organisms required to infect and the effectiveness of therapy in a given disease are significantly different when an animal is inoculated by different routes.[2] For instance, infection of the lung with Streptococcus or with the anthrax bacillus is a much more severe disease than infection of the skin. There is some experimental evidence that the inhalation of infectious particles with diameters of 1 to 5 μ produces a disease that is different and usually more severe than that produced by other means of inoculation.[2] Therefore, I wish to point out specific areas in which test by respiratory challenge is important.

Chemoprophylaxis

First, in regard to the possible value of chemoprophylaxis, the questions of whether antibiotics should be stockpiled and whether they should be made available for chemoprophylaxis, or only for therapy, are serious economically.[3] Consequently, the effectiveness of chemoprophylaxis needs critical examination in the case of each infectious micro-organism. For instance, chemoprophylaxis in malaria is well established, but Ley[4] has reported on its limitations in tsutsugamushi fever (scrub typhus). At Camp Detrick we have several times used prophylactic drugs immediately after laboratory accidents with infectious cultures. Illness has not always been prevented.

It is desirable to know the magnitude of the respiratory challenge against which administration of an antibiotic would protect. The concentration of any dispersed infectious aerosol would not be uniform everywhere, so there would be a significant variation in the respiratory dosage. Examination is needed of other variables and alternatives, such as (1) effect of length of time between inhalation of the organisms and start of administration of the prophylactic drug; (2) value of preexisting immunization; (3) simultaneous immunization and chemoprophylaxis (In this connection, experiments by Henderson[5] showed that monkeys chal-

---

lenged with aerosols of Bacillus anthracis could be protected by use of penicillin only as long as it was continued. When therapy was discontinued on the fifth day after challenge, a large proportion of the animals developed typical anthrax and died. However, if the animals were actively immunized during chemoprophylaxis, use of the antibiotic could then be discontinued and the animals survived); (4) importance of drug-resistant strains (In some instances, the bacteria may be resistant to the most effective drugs)[1c]; and (5) duration of prophylactic treatment and daily dosage necessary to prevent relapse, to minimize development of drug-resistant strains, and to erradicate foci of organisms in the body that would otherwise reestablish the disease when the patient was subjected to stress. As an example of this last problem, at the Camp Detrick laboratories, Dr. Henry Eigelsbach found that mice challenged with Pasteurella tularensis and treated for 21 days with streptomycin were apparently cured, but, when put under conditions of stress, such as extreme changes in temperature or vigorous exercise in the metabolism cage, they relapsed into active infection and died. These problems need better solutions than are now available before the prophylactic administration of drugs can be recommended.

Treatment

Our knowledge is defective in the second area, therapy of the established illness. Almost all the questions arising in connection with chemoprophylaxis recur in considering therapy. In addition, there is another problem that is coming to the fore, namely, that of the systemic toxicity that continues despite death of the bacteria. There is increasing recognition of diseases in which death of the patient may occur, even though the causative bacteria cannot be isolated at autopsy.[6] In other words, administration of large amounts of an antibiotic virtually sterilizes the patient, yet the toxins or toxic processes established by the bacteria produce a bodily change that results in death. There is a span of time during which the causative organism cannot be isolated from the living patient, and, somewhere in this period, there is a point before which death can be averted but after which death is inevitable under present conditions of available therapy. This is the "point of no return."[7] This point of no return is new only in that experience with antibiotics has allowed us to recognize it.

This phenomenon therefore calls for increased attention to the nonspecific factors that affect immunity. These have been reviewed recently by Nungester.[8] In particular, there is need for attention to possible neutralizers of the toxic products resulting from microbiological invasion. These toxic products may be the critical factors in the new point of no return. In addition to the well-known exotoxins of the bacilli causing diphtheria, tetanus, and botulism, there have been significant toxins derived from other bacteria[9] and from the viral-rickettsial group.[10] It is significant that chlortetracycline has a neutralizing effect on rickettsial toxins.[10] One of the latest is a toxin from the anthrax bacillus, formed only in vivo and associated in a curious and yet not completely known fashion with the anthrax-immunizing antigen.[6a] These considerations lead me to recommend increased emphasis upon study of the toxic processes that occur during acute infections, so that rational procedures may be devised for therapy in cases that are too far advanced to be controlled by use of antibiotics alone.

Antiserum

Our defenses are also weak in the third area, antiserums for diphtheria, tetanus, and botulism. It seems clear that supplies of equine antiserum cannot be produced or stockpiled in quantities adequate for even a moderate outbreak of illness caused by widespread dissemination of the organisms or their toxins. In view of the great advances in chemistry in the past 50 years, it should be possible to develop a chemical neutralizer for these toxins that would remedy this situation. The value of antiserum in the treatment of disease produced by aerosol-disseminated toxin has not been critically examined.

Rapid Laboratory Diagnosis

The fourth area in which respiratory challenge is important, rapid laboratory diagnosis, is a very important consideration in the treatment of infectious disease. The pharmaceutical industry has always been active in this field, and excellent improvements have been made. The Camp Detrick laboratories also have a comprehensive program on rapid detection, with emphasis upon examination of all possible avenues of approach. Extensive use is being made of contracts with private and public medical laboratories and of cooperation with the United States Public Health Service. Some of the interesting methods being examined for potential usefulness are rapid biochemical and bacteriophage techniques, slide agglutination, substrate utilization techniques, and infrared spectrophotometry. The results of these investigations will be made public, in accordance with the Department of Defense policy of releasing medical information pertaining to prevention, diagnosis, and treatment. A paper has already appeared on infrared spectrophotometry.[11]

Vaccines

Vaccines and toxoids constitute the fifth area in which the concept of respiratory challenge is important. This is where probably the best progress is being made, in terms of value to public health practice. The Civil Defense Administration has pointed out,[1a] "Active immunization offers by far the most effective form of civil defense against biological agents for which vaccines are available." Here we are confronted with the fact that a vaccine that will protect against intraperitoneal challenge will not necessarily protect to the same degree against respiratory challenge.[12] Therefore, it would be best to make sure that the vaccine produces respiratory immunity. As in chemoprophylaxis, it would be well to determine the degree of immunity in terms of resistance to an increasing number of organisms.

Another sort of problem is posed by diseases such as tuberculosis in which previous infection or immunization produces a state of hypersensitivity to the causative agent or its products.[13] Immunization might cause such a reactive state that respiratory contact with a large amount of infectious agent could induce a more severe disease than in the absence of immunization. Investigation of this possibility and of therapeutic procedures in hypersensitive reactions of this sort might prove worthwhile.

In this matter of vaccines, I should like to make two recommendations. The first concerns the possibility that an effective immunizing antigen may be present in the culture filtrate when the killed bacterial cells themselves have little or no immunizing activity. Anthrax has become the classic model for this situation. The presence of immunizing antigen in the edematous fluid of anthrax lesions has been known for many years. More recently, Gladstone[11] demonstrated that this antigen was elaborated in vitro when B. anthracis was grown in plasma under particular conditions. Subsequent investigations have been carried out in the Camp Detrick laboratories by Dr. George Wright and his collaborators.[15] In brief, it has been possible to produce the antigen in chemically defined, nonprotein mediums, and alum precipitation of the sterile culture filtrate has yielded a stable and acceptable product that produces effective immunity in a number of animal species. Evidently elaboration of the antigen is associated with a particular kind of metabolic activity of the organisms; many mediums may be devised that support excellent growth, but in which elaboration of antigen cannot be detected. We do not know the extent to which other infectious organisms may behave in an analogous way, but it would seem that the concept of a filterable antigen formed under particular conditions of growth may be a promising approach to the development of vaccines for diseases for which there is now no adequate immunizing substance.

The second recommendation relates to the potentialities of combined vaccines. It is realized that vaccines are not available for all infectious diseases and that there are other difficulties. However, these disadvantages become less important if a standard vaccine already in use by civil or military authorities is combined with vaccine for diseases less prevalent but more severe. It is proposed that such prototype combinations be made, tested, standardized, and adapted to commercial production and the technical directions for preparation be pigeonholed for possible future need. As new vaccines are developed in Camp Detrick laboratories or elsewhere, they will be brought into this plan. We are at present engaged in a small program of this kind. This, of course, is just an extension of a trend in vaccines for preventive medicine that has been present for some time but that, if accelerated, would be more valuable. The combined vaccines used in pediatric practice have been well received by doctors and patients, and the combined typhoid-paratyphoid A and B and cholera vaccine is of long standing. Successful use of the combined immunizing antigens for typhoid, paratyphoid A and B, tetanus, and diphtheria has been reported.

Combination of living vaccines may be more difficult, but it is encouraging that the combined living yellow fever and smallpox vaccines have been used successfully in man.[16] It is desirable that exploratory combinations be made with others, such as the living Rift Valley fever vaccine[17] and the chick-embryo rabies vaccine,[18] in order to determine existence of potentiation or interference. Such studies as this have been made recently with combined living dengue and yellow fever vaccines.[19] Combination of living bacterial vaccines appears to be an unexplored field.

A major obstacle to critical examination of the usefulness of living or killed vaccines has been the reluctance to inoculate man with living vaccines or to test his immunity by challenge with living organisms. An indirect benefit of the trials in Nuremberg, Germany, to the medical profession has been that the conditions justifying the use of man in medical experimentation have been accurately defined.[20] A nonexhaustive survey of the literature shows that man has been inoculated with living vaccines for plague,[21] tsutsugamushi fever,[3] typhus,[22] poliomyelitis,[23] tularemia,[24] dengue,[19] tuberculosis (BCG vaccine), rabies,[18] Colorado tick fever, infectious hepatitis, influenza, and mumps,[25] in addition to the standard living vaccines for smallpox and yellow fever. Furthermore, the natural or acquired immunity or response to therapy of man has been challenged with the living micro-organisms of malaria,[26] typhus,[22] brucellosis,[27] syphilis,[28] tsutsugamushi fever,[29] dengue,[30] and yellow fever (classic) and the virus of serum hepatitis.[31]

Very little has been done by way of respiratory challenge of man with micro-organisms, although cautious experiments have been done with gases, especially in the testing of gas masks. In some instances, adequate evaluation can be obtained in no other way, despite extensive experimentation in animals. Some of the important reasons for the absence of the use of respiratory challenge in microbiological experimentation are the complexity, cost, and infectious hazards associated with the necessary aerosol-exposure equipment.

Means of Respiratory Challenge

The Reyniers exposure chamber[2b] and various modifications thereof are suitable for exposure of laboratory animals and for study of basic problems of size, dispersion, and stability of aerosolized particles. However, its construction is elaborate and its operation difficult, so that a large operating and supporting staff is necessary.

Fortunately much excellent work can be done with simpler equipment.[2a] A device that has been very useful to us is an animal exposure tube known as the Henderson apparatus, developed by Dr. David Henderson and associates of Porton, England. The design drawings and working directions can be made available to qualified organizations. I should like to see this equipment put into use in the research laboratories of our medical schools and pharmaceutical firms. It is desirable that some mechanism be provided so that it can be given to selected academic institutions. I do not believe respiratory disease can be properly studied with infection by intraperitoneal injection or intranasal instillation. The Henderson apparatus can provide rather accurate respiratory dosages under controlled conditions. The English workers use it on an open bench and wear gas masks and other protective clothing. One small well-trained group has done this successfully for four years without infection despite considerable work with Past. tularensis. I prefer that it be enclosed in a ventilated safety cabinet and then masks worn or not, depending upon the organism in use and the state of immunity and therapy.

Summary

Study of the significance to public health of the respiratory route of infection has revealed problems in the pathogenesis, prophylaxis, and therapy of respiratory disease that can be adequately examined only by experimental respiratory challenge. These examinations have yielded, and will continue to yield, advances in medical science for the benefit of all mankind.

COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

H. D. KAUTZ, M.D., *Secretary.*

Use of Sodium Acetrizoate for Cerebral Angiography

The Council was requested to evaluate the usefulness and safety of sodium acetrizoate for cerebral angiography. This water-soluble organic iodine compound previously has been found suitable as a contrast medium for intravenous (excretory) urography, retrograde (transureteral) pyelography, intravenous nephrography and angiocardiography, translumbar arteriography, and intraductal cholangiography. On the basis of currently available evidence, the Council concluded that it is also useful for the visualization of the cerebral arteries; however, sufficient evidence and clinical experience have not been accumulated to permit a definite conclusion regarding its efficacy or toxicity as compared to other agents used for this purpose.

The dosage of sodium acetrizoate for cerebral angiography varies, but in general the total volume administered as a single injection probably should not exceed 10 cc. This is injected as a 30% solution into the external carotid artery immediately before roentgenographic exposure. Severe and dangerous reactions may occur if the 70% solution is injected accidentally; hence, extreme caution should be exercised regarding the proper concentration.

The Council voted to amend New and Nonofficial Remedies accordingly to describe the use of sodium acetrizoate for cerebral angiography.

Mallinckrodt Chemical Works cooperated by furnishing scientific data to aid in the evaluation of the use of sodium acetrizoate for cerebral angiography.

DELIVER US FROM EVIL

GUEST EDITORIAL

Thomas A. Dooley, M.D.

The author of the now widely read book "Deliver Us from Evil" is a young physician who saw, while in the United States Navy, the atrocities that can be committed during war. He improvised a medical camp at Haiphong in North Viet-Nam and became an unsung hero to the natives during the evacuation of North Viet-Nam. With 600,000 refugees to worry about he knew no cessation from his own battle against disease and propaganda that taught, among other things, that Americans were monsters who ate their own children.

Dr. Dooley's book is the subject of a movie now being made. He has resigned from the Navy to return as a civilian to the area where he believes so much can be done. Elsewhere in this issue (page 65) are printed the plans for the medical mission to the kingdom of Laos. Its real title is "Operation Laos of the International Rescue Committee." This organization cannot give Dr. Dooley financial support, so he is using the royalties from his book to pay for the mission. Not long ago Dr. Dooley wrote to the Editor, in part: "Asking around the country to the large pharmaceutical houses and business concerns has given me real insight into our capitalistic system. It has splendor and wonder. Every single outfit I requested supplies from has given me about five times what I asked for . . . yesterday Willys gave me a jeep and the Navy an eight-month supply of field rations . . . if you have a minute say a short prayer for my new work."

Dr. Dooley, all of us send our prayers to you for your work, and we also pray you can help others less fortunate than us to understand the benefits of freedom and of the way of life that is possible only under freedom.—ED.

It is a not-so-pious platitude of godless communism that 90% of the world is steeped in misery and wretchedness. Adding together the massive millions of China, India, Russia, and the uncounted masses of dark Africa, one indeed finds the number to be formidable, especially when the number is compared to the near-minute 170 million Americans who live in comfort. In misery one finds discontent. Discontent breeds the potential for revolution. Moscow-trained professional revolutionists throughout the world are fanning the passions of this discontent. We have witnessed the earth-shaking results.

Including the neutrals of the world, if there really are such things, the professional revolutionists of Stalin have succeeded in wrenching half of all mankind from freedom and plunging them behind a curtain of silence, of iron and bamboo. From the time of the Bolshevik revolution, through the flight to freedom of Viet-Nam at this very moment, hundreds of thousands of people have tried to leave, to escape, to crack through this curtain and achieve or regain their liberty. To them "liberty" and "freedom" have a living value. They are not terms thrown around promiscuously by national leaders, but they are succinct, terse cages in which magnificent ideas are held; they are living, thriving entities portraying all that is goodness. Liberty and freedom to those behind the curtain are a pounding, ever-present dream.

To dream is easy. To escape is difficult. I saw 600,000 who fled. The memory returns like a searing flame. Their anguish. Their panic. Their tears. Their haggard women. Their exhausted children. Their fear. The atrocities. The horror. The death. No one who has ever witnessed such a heartbreaking exodus will forget it for the rest of his life.

It has long been known that a vital and powerful arm of foreign policy of any nation is to be found in medicine and the men of medicine. As physicians in a free land we find within the hierarchy of our duties that we can be of special service to our country as instruments of that policy. American medicine in foreign lands primarily as help but secondarily as an illustration of the intentions, achievements, and policy of our land—herein is our special service. Herein is our nation's special strength. Progress comes of making the most of our strength rather than looking for ways to repair weakness. Fulfilling this service, utilizing this strength, is the highest achievement of honor and duty for American physicians in this time of history bullied by ruthlessness, ravage, and ruin. This challenge to help on distant soil is flung to each American doctor from the first day out of his internship to the last day before he lays down his stethoscope.

Medicine in the underdeveloped, stricken areas of the world has many facets. One large aspect is to be found in aiding those who have escaped from the claws of communism. In Viet-Nam, Laos, Cambodia, Thailand, Formosa, Malaya, India, Israel, and Jordan literally millions of humans are living in temporary shelters, in huge tent-cities, in small wooden huts—in refugee camps. Here a doctor finds the gauntlet hurled at him.

The problems confronting the new doctor in a refugee camp, especially if he is young and inexperienced, appear at first sight to be staggering. As times goes on, they remain staggering. Years later, when the doctor sits in the dressing room of a stateside operating room suite and discusses the problems of his "old refugee camp" half a world away, the problems still loom up staggering. Our schooling is not directed toward this type of practice. I distinctly remember my professor in medical school speaking of smallpox and saying, "Don't worry, you graduates of '53, unlike those of '23, will never see smallpox." One year later, in a three-day period, I lost 157 children from this putrid horror alone.

The problems that the doctor will have to handle in a refugee camp, especially in Asia, fall into two categories: medical problems, usually of an epidemic nature, and sociologic problems, often more overwhelming. The second category is more important, because unless these problems are resolved, at least to a marginal extent, no medicine can be passed out, not a needle can touch the skin, not a person will have any trust.

The medical problems need little explanation; mention will be enough. The task of feeding is enormous. One must have nourishing and palatable food, palatable by their taste-test, not ours. In Viet-Nam we gave 600 gm. of rice to each person per day, along with one fish and some foul-smelling local sauce made of decaying carp (*nuoc mom* is called the chili sauce of the Orient).

Potable water must be processed. This is extremely important. We had a small Navy machine that did our job, filtering and chlorinating one gallon per refugee per day. Sometimes this was as much as 15,000 gallons per 24-hour period. There are disposal problems. Disposal of waste cooking products was an extremely small problem. Disposal of human waste products was a gigantic one. Fifteen thousand people in one relatively small camp produced a fantastic problem in plumbing. (You do not have to be a board-qualified specialist to learn this.)

Burial of the dead without offending local tradition is difficult. Though this seems a small problem, one soon runs out of available cemetery space when he loses 15 to 20 people a day. In Viet-Nam we buried one coffin on top of another, with one religious service per three coffins. The refugees of North Indo-China had undergone atrocity and torture and in many areas had suffered from starvation. They arrived in our camps barely clinging to life. Many lost hold.

Immunization against cholera and smallpox is imperative; I wish the pharmaceutical houses would develop one vaccine for the two and one that would not require refrigeration. Though cholera annihilated villages up the delta from our camp, we had no epidemics within the camp proper. Smallpox was rampant in the North, but, when the refugee children arrived with the pox, they were immediately isolated. Rarely did new cases spring up from within the camp. Isolation techniques similar to U. S. standards were impossible, but a feeble attempt met with some success.

The diseases seen at sick call daily were like the index to the tropical medicine course. With no electricity, no x-ray, no laboratory, no nurses, and no microscope, one finds oneself saying, "It looks like the picture, smells like they say it should, has a few of the characteristic signs and symptoms—it must be—I'll treat it as if it was, if the patient is cured in 10 days —I was right." This is offensive to many in medicine, but the exigencies of the situation sometimes rob us of our highest ideals. There are no purists working in a refugee camp.

Surgery should never be attempted unless absolutely needed. News of one death from a scalpel or even weeks after a surgical procedure will spread around the camp, and the doctor will be in a situation where he has 15,000 people in his camp and no one will let him touch them. Skin infections are common in the Orient and can frequently be cured rapidly. The clearing up of a micrococcic skin infection with the miraculousness of a penicillin-effected remission of yaws is the most spectacular cure encountered. The "propaganda" effect on natives is amazing. One assumes a godlikeness in a village when he eradicates yaws. And it is a relatively simple task to do this. (No worry over sensitivity tests or tolerance here.)

I believe, however, in spite of the medical problems encountered, the sociologic problems and their ensuing complications are far more important. This is especially true in the Orient. Let us not forget for one minute that the majority of the people one will see in such a situation as we had in Indo-China will be of a group who have seldom seen a white man. They have never seen a physician. They have never ever seen an American. The majority of the people believe that, when a child has a swollen belly, a palpable spleen, and a blazing fever, he dies. The idea of chloroquine curing this child's malaria is unbelievable. Let us not forget that the type of people that one will find in a refugee camp truthfully believe that it is just as normal to find death stalking every child and every infant as we in America believe it is normal to find death stalking a man in his 80's.

In a refugee camp, then, the physician suddenly finds himself a number of "persons"—the first doctor, the first American, the first Caucasian, the first believed-to-be-monster—and, in a short time, if he does not do an adequate job, he will be the first to be asked to leave, sometimes forcibly. Sociologically he has to combat centuries of tradition and custom. Though they do not sound important, tradition and custom are as real and thriving as they are appalling and frustrating. Strings around the wrists, beads around the neck, tobacco into the ears, and hundreds of other medieval—no, earlier than medieval—customs still command the Orient. The high priestess of these is the grandmother. The grandmothers of Asia are 10 times worse than the most malignant mothers-in-law of America. If you can win the haggard, wrinkled old grandmother to your side and get her to believe in penicillin, or sometimes even soap and water, then you can easily convince the rest of the village.

Understandably the people have a great fear of the American. Never have they seen a person so fast, so strange, so tireless, so mechanical, and with such odd looking orbital structures. (He looks well fed; does he really eat children?) Even to many American patients the doctor's armamentarium of glistening instruments is a sight to behold. Put a mirror on your head, a stethoscope around your neck, a syringe and needle in your hand, and a table of glass jars in front of you; paint an arm with Merthiolate; and speak a mumbo jumbo called medical English—you certainly are frightening.

In some areas of the Orient there is a very special problem, Communist propaganda. This follows the same pattern as used in other parts of the world. That aimed at medicine usually proclaims that our needles will inject bacteriological warfare, our DDT will render the people sterile, and our soaps on a child's scalp will make him feeble-minded. They claim we will bring air-borne death to the earth-born people of Asia. Doctors are a special brand of ogres developed in monstrous America and sent to foreign lands to experiment fiendishness. To overcome this we must show persistence in our gentleness. We can never run out of compassion. We must understand and grow to love our patients. The former is always hard, but the latter is an easily acquired joy. With perseverance we can show our nation's policy of aid and God's policy of charity to our brothers. Dr. Albert Schweitzer was correct when he said, "I don't know what your destinies will be, but one thing I know: the only ones amongst you who will be really happy are those who will have sought and found, how to serve."

To implement our foreign policy of aid and help to those underdeveloped and threatened communities of the world, a physician has a special calling. Through the World Health Organization, UNESCO, CARE, the International Rescue Committee, the Public Health Service, the State Department, the International Cooperation Administration, and a myriad of other such organizations, we can work to help those who, like my sailors used to say, "ain't got it so good."

From a war not so long ago, though two have succeeded it, there emerged a great poem, "Flander's Field." The closing lines said: "Take up the torch from we the dead." The hands of medicine, with gentle arms extended to noble but wretched people, can best hold up the torch of light, the torch of health, the torch of freedom.

MEDICAL EXAMINER VERSUS CORONER SYSTEM

At irregular intervals for over 100 years, the American Medical Association has been concerned with the need for improvement in both the quality and the quantity of medicolegal investigations in many parts of the United States. In 1855 a committee was appointed by the House of Delegates of the American Medical Association to report what measures should be adopted to remedy the evils then existing in the methods of holding coroners inquests "by which the lives and liberties of the innocent may be jeopardized, and the ends of justice frustrated." Through the years committees were appointed, investigations and studies made, and reports given, and in 1948 the House of Delegates adopted a report of its Reference Committee on Reports of Board of Trustees and Secretary that stated in part: "The Medical Examiner: It is noted with considerable interest that the coroner-medical examiner system is gradually replacing the old coroner system. . . . Your committee wishes to reemphasize the previous pronouncements of this House in favor of the medical examiner system to replace the antiquated coroner system."

A few years later, the American Medical Association, through the Committee on Medicolegal Problems and the former Bureau of Legal Medicine and Legislation, collaborated with a number of other interested organizations (American Bar Association, American Academy of Forensic Sciences, American Judicature Society, National Municipal League, and National Civil Service League) in the preparation of a draft law that could be used as a model by state legislatures wishing to take action in this field. The result of this collaboration was the approval, in 1954, by the National Conference of Commissioners on Uniform State Laws of a "Model Post-Mortem Examinations Act." The purpose of this act, according to a prefatory note of the commissioners, is "to provide a means whereby greater competence can be assured in determining causes of death where criminal liability may be involved." Unfortunately, copies of the model act were not available for distribution until too late for the 1955 state legislatures to consider the subject matter represented by its provisions.

Often in the past, the pages of The Journal have reflected the opinion of the profession that there is much room for improvement in the quality and quantity of medicolegal investigations and have urged the profession to take the steps necessary to accomplish such improvement. Now is the appropriate time for committees of state medical societies to consider the creation of a statewide medical examiner system in formulating programs for presentation to the 1957 state legislature.

According to the National Municipal League, which is spearheading the campaign to improve state medicolegal investigative facilities, substantial compliance with the principles of the model law now exists in Massachusetts, Maryland, Virginia, Arkansas, Rhode Island, North Carolina, Georgia, Vermont, Louisiana, and parts of other states; in four populous counties in Texas; in Arizona,, Detroit, Philadelphia, Los Angeles, Miami; and under new permissive laws in some counties of Michigan, New York, and North Dakota. In addition, Oregon will vote in November, 1956, on a constitutional amendment to remove coroners from the state constitution.

The fact that many of these endeavors received active support from the physicians in the areas involved indicates that the profession is not insensitive to its civic obligations. State society legislative committees that are laying the groundwork for this kind of activity during 1957 would be well advised to welcome the help that can be given by the National Municipal League in acquainting legislators with the provisions of, and need for, a Model Post-Mortem Examinations Act.

ORGANIZATION SECTION

THE SCIENTIFIC EXHIBIT AT CHICAGO

REPORT OF COMMITTEE ON AWARDS

The Committee on Awards has made the following report of the awards given at the 1956 Annual Meeting of the American Medical Association.

Hektoen Medal

The Hektoen Medal is presented for exhibits of original investigation, which are judged on the basis of originality and excellence of presentation. Three awards are made, consisting of gold, silver, and bronze medals.

Hektoen Gold Medal to Samuel Rosen, New York, for the exhibit on Mobilization of Stapes for Otosclerotic Deafness.

Hektoen Silver Medal to Edwin H. Ellison, Ohio State University Health Center, Columbus, Ohio, for the exhibit on the Ulcerogenic Tumor of the Pancreas.

Hektoen Bronze Medal to Harold J. Magnuson and Joseph Portnoy, Public Health Service, Department of Health, Education, and Welfare, Washington, D. C., for the exhibit on Treponema Pallidum Complement-Fixation Test.

Billings Medal

The Billings Medal is presented for exhibits that do not exemplify purely experimental studies but are judged on the basis of excellence of correlating facts and excellence of presentation. Three awards are made, consisting of gold, silver, and bronze medals.

Billings Gold Medal to W. D. Snively Jr., M. J. Sweeney, and Martha Wessner, St. Mary's Hospital, Evansville, Ind., for the exhibit on the Body Fluids: Foundation Facts, Clinical Diagnosis, Therapy.

Billings Silver Medal to R. B. Hogan, M. M. Brooke, G. R. Cooper, D. S. Martin, and M. Schaeffer, Communicable Disease Center, Public Health Service, U. S. Department of Health, Education, and Welfare, Atlanta, Ga., for the exhibit on Laboratory Techniques in the Diagnosis of Communicable Diseases.

Billings Bronze Medal to Roderick D. Turner and Elmer Belt, University of California School of Medicine at Los Angeles, for the exhibit on Surgical Techniques of Total Perineal Prostatectomy.

Section Awards

Certificates of Merit and Honorable Mention were awarded to the following exhibits in each Section.

Section on Anesthesiology

Certificate of Merit to Reuben C. Balagot, Rosauro Ma. Reyes, Gareth B. Gish, and Max S. Sadove, University of Illinois College of Medicine, Chicago, for the exhibit on Pulmonary Edema: Antifoam Agents.

Honorable Mention to William K. Bannister and David M. Little, Hartford Hospital, Hartford, Conn., for the exhibit on Physiological Treatment of Asphyxia Neonatorum.

Section on Dermatology

Certificate of Merit to Robert F. Tilley, John Adams Jr., Chester N. Frazier, and Robert Griesemer, Masssachusetts General Hospital and Harvard Medical School, Boston, and George Odland, Seattle, for the exhibit on Tuberculosis of the Skin.

Honorable Mention to Louis C. Zopf and Seymour Blaug, the United States Pharmacopeia, New York, for the exhibit on Dermatological Preparations.

Honorable Mention to Richard J. Rowe and Harland C. Dangle, Marshfield Clinic, Marshfield, Wis., for the exhibit on Dermatological Lesions Seen in General Practice.

Section on Diseases of the Chest

Certificate of Merit to Aldo A. Luisada and C. K. Liu, Chicago Medical School, Chicago, for the exhibit on Patterns of Cardiovascular Pressure Pulses Obtained by Catheterization.

Honorable Mention to Henry T. Nichols, Clarence Denton, and Joseph F. Uricchio, Hahnemann Medical College, Philadelphia, for the exhibit on Mitral Insufficiency: Correction by Polar Cross Plication of the Annulus Fibrosis.

Section on Experimental Medicine and Therapeutics

Certificates of Merit to Albert Sjoerdsma, Luther L. Terry, and Sidney Udenfriend, National Heart Institute, Bethesda, Md., for the exhibit on Malignant Carcinoid, A New Metabolic Disorder.

Honorable Mention to Carroll A. Handley, John H. Moyer, and R. A. Seibert, Baylor University College of Medicine, Houston, Texas, for the exhibit on the Action of Mercurial Diuretics and the Fractionation of Excretory Products.

Section on Gastroenterology and Proctology

Certificate of Merit to C. F. Code, A. M. Olsen, F. E. Donoghue, H. A. Andersen, B. Creamer, F. E. Fyke Jr., and A. H. Bulbulian, Mayo Clinic and Mayo Foundation, Rochester, Minn., for the exhibit on Esophageal Motility: Dynamics of Deglutition in Health and Disease.

Honorable Mention N. C. Hightower, A. C. Broders Jr., R. D. Haines, A. W. Sommer, and J. F. McKenney, Scott and White Clinic, Temple, Texas, for the exhibit on Chronic Ulcerative Colitis: Diagnostic and Therapeutic Considerations.

Honorable Mention to David C. H. Sun and Harry Shay, Temple University School of Medicine, Philadelphia, for the exhibit on Value of Proper Dosage of Anticholinergic Drugs in Treatment of Peptic Ulcer: Optimal Effective Dose.

Section on General Practice

Honorable Mention to Franklin M. Foote, Willis S. Knighton, and Virginia Smith Boyce, National Society for the Prevention of Blindness, New York, for the exhibit on Early Detection of Glaucoma.

Honorable Mention to H. E. Nieburgs, Beth El Hospital, New York, for the exhibit on Control of Cervical Carcinoma by General Population Screening: The Floyd County Project.

Section on Internal Medicine

Certificate of Merit to Goronwy O. Broun and Rose Rita Schmidt, St. Louis University School of Medicine, St. Louis, for the exhibit on Epidemiology of Influenza as Demonstrated by a Study of Serum Pools.

Certificate of Merit to Bernard H. Ostrow, Daniel Steinberg, Howard E. Ticktin, and John M. Evans, George Washington University School of Medicine, Washington, D. C., and National Heart Institute, National Institutes of Health, Bethesda, Md., for the exhibit on Serum Glutamic Oxaloacetic Transaminase (G. O. T.) in Myocardial Infarction.

Section on Laryngology, Otology and Rhinology

Certificate of Merit to Irving M. Blatt, Philip Rubin, James H. Maxwell, John F. Holt, and John E. Magielski, University of Michigan Medical School, Ann Arbor, for the exhibit on Secretory Sialography in Health and Disease.

The Committee on Awards was composed of the following physicians: Frank W. Konzelmann, Washington, D. C., Chairman; O. P. J. Falk, St. Louis; Richard A. Mills, Fort Lauderdale, Fla.; Sam H. Sanders, Memphis, Tenn.; and W. Walter Wasson, Denver.

Honorable Mention to Maurice H. Cottle, George G. Fischer, and Roland M. Loring, Chicago, Ralph H. Riggs, Shreveport, La., and Ivan W. Philpott, Denver, for the exhibit on Early Nasal Injuries: A Factor in Facial and Dental Deformity.

Section on Military Medicine

Certificate of Merit to Sylvester F. Williams, Elmer R. King, and T. G. Balbus, U. S. Naval Hospital, Bethesda, Md., for the exhibit on Clinical Diagnostic Studies Utilizing Radioactive Isotopes.

Honorable Mention to Charles Huggins and Edwin L. Carter, Naval Medical Research Institute, National Naval Medical Center, Bethesda, Md., for the exhibit on Experimental Hepatic Surgery Employing Differential Hypothermia.

Honorable Mention to S. W. French III, Herbert T. Berwald, and Joseph L. Hannon, Letterman Army Hospital, San Francisco, for the exhibit on the Pulmonary Coin Lesion: A Harmless Looking Killer.

Section on Nervous and Mental Diseases

Certificate of Merit to Maurice L. Silver, Providence, R. I., for the exhibit on Simplified Method of Cerebral Angiography.

Honorable Mention to Robert S. Schwab, Benjamin Castleman, Oliver Cope, Richard Sweet, James Vanderbeen, and Henry R. Viets, Massachusetts General Hospital, Boston, for the exhibit on Thymectomy in Myasthenia Gravis.

Section on Obstetrics and Gynecology

Certificate of Merit to Frederick H. Falls and Charlotte S. Holt, Illinois Department of Public Health and University of Illinois College of Medicine, Chicago, for the exhibit on Version and Extraction.

Honorable Mention to Joseph W. Kelso and Joseph W. Funnell, Oklahoma City, for the exhibit on Surgical Management of Carcinoma of the Cervix.

Section on Ophthalmology

Certificate of Merit to Bertha A. Klien, University of Chicago, the School of Medicine, Chicago, for the exhibit on Survey of Pathogenesis and Treatment of Retinal Venous Occlusion.

Honorable Mention to David Volk, Western Reserve University School of Medicine, Cleveland, for the exhibit on Aids to Subnormal Vision.

Section on Orthopedic Surgery

Certificate of Merit to D. C. Dahlin, R. K. Ghormley, E. D. Henderson, and M. B. Coventry, Mayo Clinic and Mayo Foundation, Rochester, Minn., for the exhibit on Bone Tumors: Analysis of 2,276 Primary Neoplasms of Bone Seen at the Mayo Clinic 1905-1955.

Honorable Mention to Dan R. Baker, Guthrie Clinic, Sayre, Pa., and William J. McHolick, McBride Clinic, Oklahoma City, for the exhibit on Spondyloschisis and Spondylolisthesis in Children.

Section on Pathology and Physiology

Certificate of Merit to Harry F. Weisberg, Mount Sinai Medical Research Foundation and the Chicago Medical School, Chicago, for the exhibit on a Better Understanding of Anion-Cation (Acid-Base) Balance.

Honorable Mention to Chandler McC. Brooks, Brian F. Hoffman, and E. E. Suckling, State University of New York College of Medicine at New York City, Brooklyn, N. Y., for the exhibit on Physiological States in Sleep.

Section on Pediatrics

Certificate of Merit to Willis J. Potts, W. L. Riker, Arthur DeBoer, and Thomas G. Baffes, Children's Memorial Hospital, Chicago, for the exhibit on Intestinal Obstruction in Newborn Infants.

Honorable Mention to Bohdan Dobias, New York, and Walter Mitchell Jr., Newark, N. J., for the exhibit on *Diagnosis and* Treatment of Moniliasis in Pediatrics.

Section on Physical Medicine

Certificate of Merit to Edward E. Gordon, Michael Reese Hospital, Chicago, for the exhibit on What Price Ambulation? A Study of the Indications and Contraindications for Paraplegic Ambulation.

Honorable Mention to Ray Piaskoski, Robert W. Boyle, Edwin C. Welsh, Paul A. Dudenhoefer, Albert M. Cohen, and DeLore Williams, Marquette University School of Medicine, Milwaukee, for the exhibit on Preventive Measures in the Management of the Hemiplegic.

Section on Preventive and Industrial Medicine and Public Health

Certificate of Merit to Howard Hansen, N. K. Weaver, and J. T. Perret, Esso Standard Oil Co., Baton Rouge, La., for the exhibit on Arteriosclerotic Hearts at Work.

Honorable Mention to D. O. Hamblin, Harold H. Golz, and C. Boyd Shaffer, New York, for the exhibit on Phosphate Ester Insecticide Poisoning.

Section on Radiology

Certificate of Merit to Franz P. Lessmann, Robert Schobinger Von Schowingen, Elliott C. Lasser, and Paul Zuckerman, Roswell Park Memorial Institute, Buffalo, N. Y., for the exhibit on Clinical Applications of Intraosseous Venography.

Honorable Mention to Lawrence Reynolds, William M. Tuttle, Harold E. Fulton, and George F. Boone, Harper Hospital, Detroit, for the exhibit on Preoperative Roentgen Studies in Primary Lung Carcinoma.

Honorable Mention to Charles M. Greenwald, Thomas F. Meaney, and C. Robert Hughes, Cleveland Clinic, Cleveland, for the exhibit on Chordoma.

Section on Surgery, General and Abdominal

Certificate of Merit to George T. Pack, Gordon P. McNeer, Richard Brasfield, Kathleen E. Roberts, Douglas A. Sunderland, Louis G. Ortega, and Henry T. Randall, Memorial Hospital, New York, for the exhibit on Treatment of Gastric Cancer.

Certificate of Merit to Alton Ochsner, Robert J. Schramel, John B. Blalock, Jack Harold Keeling, and Jack A. Haley, Tulane University School of Medicine and Ochsner Clinic, New Orleans, for the exhibit on Carcinoma of the Lung.

Honorable Mention to James F. Connell Jr., William Philip, Frank Gilbertson, and Louis M. Rousselot, St. Vincents Hospital, New York, for the exhibit on the Problem of the Nonadherent Surgical Dressing.

Section on Urology

Certificate of Merit to Edwin L. Prien and Burnham S. Walker, Boston University School of Medicine, Boston, for the exhibit on Salicylate Therapy for Recurrent Calcium Urinary Stone.

Certificate of Merit to Albert E. Goldstein, B. S. Abeshouse, Cafer Yildiran, Morton Goldfarb, and Hannah Silberstein, Hoffberger Urological Research Laboratory, Sinai Hospital and University of Maryland School of Medicine, Baltimore, for the exhibit on Bladder Substitutes: An Experimental Study in Dogs.

Section on Miscellaneous Topics

Honorable Mention to Oren C. Durham, Abbott Laboratories, North Chicago, Ill., and David Merksamer, Jewish Hospital, Brooklyn, N. Y., for the exhibit on Air-Borne Mold Spores in Seasonal Allergy.

Exhibit Symposium on Traffic Accidents

Certificate of Merit to Claire L. Straith, Richard E. Straith, Joseph D. Carlisle, and Burns G. Newby, the Straith Memorial Hospital, Detroit, for the exhibit on Treatment of Traffic Injuries.

Honorable Mention to E. C. Paul, Indiana State Police, Indianapolis, for the exhibit on Auto Crash Injury Research.

Exhibit Symposium on Arthritis and Rheumatism

Honorable Mention to L. Maxwell Lockie and John H. Talbott, University of Buffalo School of Medicine and Buffalo General Hospital, Buffalo, N. Y., for the exhibit on Gout.

Honorable Mention to Edward W. Lowman, Institute of Physical Medicine and Rehabilitation, New York, for the exhibit on Self-Help Devices for the Arthritic.

Subsidized Exhibits

The Committee on Awards commends highly the Special Exhibits on Fractures, Gross Pathology, Pulmonary Function Testing, P. E. for every M.D., and the Cardiovascular Demonstrations.

Appreciation

A Certificate of Appreciation is awarded to J. M. Sanchez-Perez, Mexico City, Mexico, for the exhibit on Automatically Controlled Stereo-Serio-Cerebral Angiography.

A Certificate of Appreciation is awarded to André Mackay, Armand Trépanier, and Maurice R. Dufresne, Hospital Notre Dame, Montreal, Canada, for the exhibit on Selective Segmental Bronchography.

Comment

The Committee on Awards wishes to point to the improvement in the general excellence of presentation and also to the increasing interest in original investigation of high quality that has brought forth meritorious exhibits in this class. It, therefore, wishes to commend all of the other exhibitors for their efforts in the preparation and diligence in the demonstration of their exhibits.

The Committee also wishes to commend the professional staff of Dr. Thomas G. Hull for their efforts in making this Scientific Exhibit a success.

ACTIONS BY BOARD OF TRUSTEES

The following actions were taken by the Board of Trustees at its meeting in Chicago on June 7-14, 1956.

Clinical Meeting

Dallas, Texas, was selected by the Board of Trustees as the place for the 1959 Clinical Meeting of the American Medical Association. A suitable date will be selected at a future time.

Military Medical Activities

The Council on National Defense was authorized to continue its study of the "Doctor-Draft" act, which expires on June 30, 1957. The Council feels that additional information is needed before a recommendation can be made to the Board on this subject.

An expanded public relations program on military medical activities of the Council on National Defense, its Committee on Military Medical Affairs, and the American Medical Association was approved. It is planned to publish more material in THE JOURNAL, the *Armed Forces Medical Journal,* and the *Student A. M. A. Journal* on subjects of interest to the profession.

The Board also approved a recommendation that the dual compensation laws restricting the employment of retired officers by the federal government be revised. A relaxation of the current laws would permit the employment of experienced personnel in the fields of medicine, electronics, guided missiles, radar, and atomic energy. These are all fields vital to the national defense.

Authorization was given to send a letter to the Secretary of the Navy and the Secretary of the Army urging the Secretary of Defense to issue the necessary directive so that medical control of the Armed Forces Medical Procurement Agency would be maintained through the retention of the surgeons general of the departments of the Army, Navy, and Air Force for advice, selection, and control of items of medical equipment and supply necessary in the proper scientific treatment of patients.

Rural Health

Approval was given to a request from the Council on Rural Health for a conference of state rural health chairmen, to be held at Purdue University in the fall of 1956.

Industrial Ophthalmology

The Board authorized the appointment of an advisory committee on industrial ophthalmology by the Council on Industrial Health. The members of this committee will be selected from the field of ophthalmology, rather than from any special group, and will function under the aegis of the Council. This committee replaces the present committee on this subject of the Section on Ophthalmology of the A. M. A.

World Medical Association

In response to a communication from the secretary general of the World Medical Association, the Board referred to the Council on Medical Service, for its study, the question of the role of the individual physician in the field of preventive medicine and what the principles should be in establishing cooperation between practicing physicians and public health officials.

The Board also voted not to approve of the World Medical Association assuming "administrative responsibility" for international awards.

Dr. Raymond B. Allen has accepted the presidency of the Second World Conference on Medical Education sponsored by the W. M. A., to be held in Chicago in 1959. A program committee for this conference has been appointed.

World Health Organization

The 10th anniversary of the signing of the constitution of the World Health Organization will occur in 1958. The Board supported a suggestion that an invitation be issued to hold the 1958 World Health Assembly in the United States.

Public Relations Conference

At the request of the Public Relations Department, the Board authorized discontinuance of the Public Relations Conference usually held prior to the Clinical Meeting of the Association.

Postgraduate Medical Education

Approval was given to the Council on Medical Education and Hospitals to appoint an *ad hoc* advisory committee on postgraduate medical education to assist in the planning in this field.

Committee on Rehabilitation

The following members have been appointed to the Committee on Rehabilitation, representing the Council of the Association as indicated: Drs. H. B. Mulholland, Council on Medical Service; Francis J. Gerty, Council on Mental Health; Guy Caldwell, Council on Medical Education and Hospitals; and O. A. Sander, Council on Industrial Health. As soon as a nomination has been received from the Council on Medical Physics, a representative from this Council will be appointed.

Appointments

The following appointments to councils, committees, and special functions were made:

Dr. Rolf Schloegel, temporary consultant to the Council on Medical Service.

Dr. Carroll Andrews, to fill the unexpired term of Dr. Robb Smith on the Council on Rural Health.

Dr. D. Denny-Brown, to succeed Dr. Puttnam, and Drs. George Gardner, Douglas Orr, M. Ralph Kaufman, and Fritz Redlich as additional members on the editorial board of the *A. M. A. Archives of Neurology and Psychiatry.*

Dr. Victor Goodhill, to fill the unexpired term of Dr. J. Mackenzie Brown, and Dr. George Shambaugh Jr., as an additional member on the editorial board of the *A. M. A. Archives of Otolaryngology.*

Dr. B. Dixon Holland, to fill the unexpired term of Dr. Carl Peterson on the editorial board of the *A. M. A. Archives of Industrial Health.*

Dr. Henry A. Davidson, to succeed Dr. Francis J. Gerty on the Committee on Medicolegal Problems.

Dr. Jay Johns, to succeed Dr. Ray O. Bjork on the Joint Committee on Health Problems in Education.

Dr. James R. Reuling, Chairman, to succeed Dr. David B. Allman, and Dr. James R. McVay, an additional member on the Committee on Legislation.

Council on Constitution and Bylaws, Dr. James R. Reuling, ex officio.

Task Force on Dependent Medical Care, Drs. E. S. Hamilton, Chairman, James R. Reuling, Hugh H. Hussey Jr., and Joseph D. McCarthy.

Alexander Hamilton Bicentennial Commission

At the request of the director of the Alexander Hamilton Bicentennial Commission, several names were suggested for membership on its Medical Advisory Committee.

Nurses and Nursing

Dr. Julian P. Price and Mr. C. Joseph Stetler were appointed to represent the Association at a meeting to be called by the American Nurses' Association for a discussion of legal and legislative implications of the extended functions required by nursing personnel during disasters.

Clinical Psychologists

The question of the future position of the A. M. A. with respect to certification or licensure of clinical psychologists was referred to the Law Department and the Council on Mental Health for study, analysis, and recommendation.

Grievance Committees

Authorization was given for the preparation of an appendix to the Guides for the Organization and Operation of Grievance Committees, as recommended by the House of Delegates at its meeting in Boston, December, 1955. This appendix will be prepared by members of the staff of the headquarters office.

RESULTS OF EXAMINATION OF PHYSICIANS AT CHICAGO MEETING

The Section on General Practice of the American Medical Association sponsored chest examinations for physicians at the recent meeting of the American Medical Association under the heading "A P.E. for Every M.D." Arrangements were made in the Scientific Exhibit for electrocardiograms and for chest x-rays. These were carried on in cooperation with the National Tuberculosis Association, General Electric X-ray Corporation, and numerous cardiologists and chest physicians.

The results of the examination of the physicians are as follows:

965 Chest X-Rays	No.	%
Negative findings	861	83.5
Suspected tuberculosis	58	6.0
Cardiac findings	42	4.3
Other pathology	59	6.1
1,083 Electrocardiograms		
Negative findings	821	84.9
Abnormal	97	10.0
Borderline	49	5.1
Survey sheets not returned	116	

It is not to be interpreted from the above findings that 6% of the physicians attending the Annual Meeting had tuberculosis. There are many factors to be considered, but the findings do indicate that many of the physicians who were examined on Navy Pier should have further and more complete examinations at home. The Section on General Practice is doing a service to medicine in promoting this project.

JOINT BLOOD COUNCIL MEETING IN CHICAGO

At its June 15 meeting in Chicago the board of directors of the Joint Blood Council gave the go-ahead signal for projects concerned with collection and dissemination of information, improvement of relations within the blood-banking field, accreditation and other administrative problems, and scientific research. A summary of the board's major actions is given below:

Officers Elected

Drs. LeRoy E. Bates and Roger W. DeBusk of the American Hospital Association and Dr. Sam T. Gibson of the American National Red Cross were appointed to fill places on the board; others continuing on the board are Drs. Leonard W. Larson, Walter B. Martin, James J. Griffitts, E. Eric Muirhead, Donald H. Kaump, and Frank W. Konzelmann and Mr. Charles H. Kellstadt. Dr. Bates was elected treasurer, and the following officers were reelected: Drs. Leonard W. Larson, president; James J. Griffitts, vice-president; and Frank E. Wilson, vice-president and secretary.

Dissemination of Information

A nationwide survey of blood banks was authorized, to be carried out under the direction of Dr. Frank E. Wilson, Washington, D. C., executive vice-president of the Joint Blood Council. A national blood banks directory, to be based on the survey findings, will contain the following information: location and areas served by individual blood banks and hospitals; how each is operated, organized, and supervised; whether commercial or nonprofit; adaptability for expansion in a national emergency; volume of business; and relationship of each blood bank to allied services, such as tissue banks. The directory also will contain a glossary of terms and definitions used in blood banking and blood research.

Authority was given for creation of a bureau of information as a clearing house on progress being made everywhere in all aspects of blood banking and blood research. The information will be sent out by the Joint Blood Council office to each member institution, the scientific committee, the board of directors, journals of member institutions, and others requesting it.

Also approved was a recommendation that a national diagnostic center or reference library be established to make available information on ways to stimulate the study of unusual serums and red blood cells. In this connection, the scientific committee was requested by the board to further study the problem of maintaining national and local blood donor registries for the rarer blood groups.

Relations with Organizations and Industries

Because of reports that the pharmaceutical industry is not receiving enough "surplus" blood to keep its blood fractionating facilities in operation, the board voted the president authority to appoint an ad hoc industry liaison committee to look into this situation. The following persons were appointed: Drs. James J. Griffitts, chairman, Frank W. Konzelmann, and LeRoy E. Bates. Later, the president may at his discretion set up a permanent committee.

The board approved in principle recommendations of a temporary committee on blood insurance problems (Dr. Walter B. Martin, chairman) that immediate steps be taken to (*a*) attempt to persuade health and accident insurance companies to limit their coverage to the cost of voluntary procurement, processing, and dispensing and (*b*) encourage Blue Cross to include in its coverage the cost of processing and dispensing, without any form of donor payment or professional fee.

Accreditation, Research, and Administration

The board agreed with a recommendation of the scientific committee (Dr. Max M. Strumia, chairman) that it is imperative that minimal standards for voluntary accreditation of blood banks be decided on and widely disseminated in professional fields. The need for stimulation of research in the following areas was recognized: (*a*) long-range storage of the red blood cells; (*b*) practical means of platelet preservation; (*c*) preparation and testing of antihemophilic globulin: (*d*) the effect on the red blood cells of water-repelling surfaces; (*e*) further investigation of anticoagulant procedures, such as ion exchange resins to replace citrate in the operation of blood banks, to make possible continuous use of large quantities of blood, as required in some operative procedures; (*f*) continuance of the work to eliminate as donors possible carriers of S. H. virus, or sterilization of the blood itself; and (*g*) recommendations for ideal transfusion equipment insofar as it affects the quality of the formed elements but not necessarily the safety, already considered by the minimum requirements.

Dr. Wilson described to the board his visits to various parts of the United States to obtain an over-all picture of some of the progress and problems in blood banking. Among his other contacts, his itinerary included the following visits: Blood Banks Association of New York State; the Red Cross Regional Center in New York City; King County Central Blood Bank, Seattle; Irwin Memorial Blood Bank, San Francisco: California Blood Bank System, San Francisco: San Diego Blood Bank, San Diego: Pacific Area Clearing House, San Francisco; Southwest Blood Banks, Phoenix, Ariz.; Milwaukee Blood Center, Milwaukee; and Lansing and Battle Creek, Mich. He also visited the American Association of Blood Banks' headquarters in Dallas, Texas.

MEDICINE AND THE LAW

RIGHT OF NON-STAFF MEMBER TO TREAT PATIENTS IN PUBLIC HOSPITALS

Ordinarily a physician is the vehicle through which a patient is admitted to a hospital; however, a recent decision of the appellate division in New York[1] had the rather interesting result of making a patient the vehicle through which a physician was admitted to practice in a public hospital even though he was not a member of its active staff.

In other cases in which the right of a physician to practice in a public hospital has been in issue, the courts, if they held for the hospital, also held that the physician was thereby totally barred from using the hospital's facilities. In the Alpert case, the court held that staff membership is not necessary in order for a physician to utilize the facilities of a public hospital. It was decided that it is only necessary that the patient desire to be treated in that hospital. The decision, in effect, created a courtesy staff where none had existed before.

The city hospital of Fulton, N. Y., is publicly owned, controlled, and financed. Its affairs are managed by a board of directors that has been granted full power to make rules and regulations. Pursuant to this authority the hospital adopted certain rules, which provide, in part: "*Section 1.* Patients may be treated only by physicians and surgeons who have submitted proper credentials to the Board of Governors. Such surgeon or physician must be a graduate of a recognized medical school, legally licensed to practice medicine in the State of New York and a member of the County Medical Society where he is located and practicing medicine. *Section 2.* Any physician or surgeon wilfully violating any rule or regulation of the hospital may be denied the use of the hospital."

The bylaws of the medical staff contain substantially the same requirements for membership and provide for staff appointments to be made by the board of governors for a term of one year.

The petitioner was licensed to practice medicine in New York in 1938 and was accepted for membership on the active staff of the hospital in 1946. He remained a member of the staff until that membership was terminated in 1955 by the board of directors of the hospital. This termination not only excluded him from the hospital, it denied him reappointment to the medical staff. Thus any of his patients requiring hospitalization were required either to change physicians or go to another hospital in a distant town. The petitioner contended that such action would destroy his practice and deprive him of the right to practice medicine in that area. The facts developed in the case disclosed that the physician had advanced training and experience in medicine and surgery, that he had developed a large practice, and had a substantial investment in his office and facilities in Fulton. He alleged that the determination of the board was arbitrary and without due process of law, since he received no notice and was not granted a hearing prior to the board's ruling.

The board alleged that its determination "was reached only after a careful and mature consideration of a multitude of condemning facts and circumstances which overwhelmingly justified" its action. It contended, further, that it had uncontrolled discretion in e management of the hospital and that no court could presume to review or correct its official acts. Judicial control of administrative conduct, said the court, must be reasonable. It was pointed out that courts have often held that a regularly licensed physician cannot be denied the use of a public hospital by the operation of unreasonable rules and regulations. In this case, continued the court, the regulation itself was reasonable and the petitioner fully met its requirements. The hospital, however, relying upon the lack of any expressed limitations upon its authority, went ahead and unreasonably and arbitrarily excluded him from the use of the hospital. It did not give him either notice or hearing prior to its action. The court held that there are limitations upon the powers of the respondent hospital even though none are expressly stated in the law. These limitations are implied, said the court, by the very nature of a public hospital and also by the constitutional protection given to valuable interests.

Regulations must be consonant with the purposes of the institution for which they are made. The board undoubtedly had some discretion in excluding patients, said the court, but held that all must be accepted in a public hospital who genuinely require hospitalization and for whose ailments the hospital possesses the required facilities. For example, a regulation excluding all patients over 30 years of age or a regulation excluding all physicians but one would be void. Such regulations would convert the hospital into a private clinic. Further, the court continued, if the right of the general public to use the hospital is to have any meaning, they must have the concurrent right to be treated by their own physicians, unless the latter are excluded for adequate cause. The nature of a public hospital imposes an actual, although implied, limitation upon the authority to restrict arbitrarily the use of the hospital by the public, whether a physician or a patient.

In one sense, said the court, there is no constitutional right to practice medicine in a public hospital any more than there is an absolute right to sell alcoholic beverages or to drive an automobile. Valuable privileges, however, are entitled to the protection of law. The petitioner has enjoyed the use of the Fulton city hospital since 1946. On the record before the court, it appears that he is a capable and qualified surgeon who has developed a large practice representing a substantial investment. The determination complained of, in effect, deprives him of the right to practice medicine in the area of Fulton without notice of charges and without hearing. There was in this case a lack of procedural due process in arriving at the determination. "We conclude," said the court, "that a qualified physician admitted to practice in a public hospital acquires a species of tenure and cannot be capriciously excluded, and thereby injured financially and professionally, without notice and an opportunity to be heard."

The petitioner was therefore entitled to use the facilities of the hospital for the treatment of his patients. He was not, however, entitled to be reinstated as a member of the active staff, which consists of "those physicians who have been selected to regularly attend patients in the hospital and to whom all patients shall be assigned." Appointments to the medical staff are made by the board for a term of one year, and the respondent's failure to reappoint him to the staff gives rise to no legal remedy, nor is such reappointment necessary. He may use the facilities without staff membership so long as he obeys all reasonable rules and regulations and gives no cause for his removal. This result gives the board a free hand to control the internal management of the hospital.

For what seems to be the first time the court recognized two concurrent rights not previously separated: staff membership on the one hand and the right of a physician to use the facilities of a hospital for the treatment of his private patients regardless of staff membership.

One of the logical results of this decision is that, at least in New York, a physician may take advantage of all of the facilities that a modern, well-equipped hospital may possess without having to participate in any way in caring for the charity patients and emergency patients who are served by that hospital. Only the staff members are obligated to perform those activities. The plaintiff was given the rights of staff membership without having to assume the obligations.

---

1. Application of *Alpert v. The Board of Governors of the City Hospital of Fulton*, 145 N. Y. S. (2) 534.

MEDICAL NEWS

ARKANSAS

Conference for the Handicapped.—An Arkansas Conference for the Handicapped has been scheduled for Oct. 9-10 at the Marion Hotel in Little Rock. Complete financial support for the conference is being furnished by the Nemours Foundation, Wilmington, Del., a charitable corporation for the furtherance of work with the handicapped child. The objectives of the conference are (1) to evaluate the presently available resources for meeting the needs of the handicapped in Arkansas, (2) to determine the present unmet needs for a program of adequate care for the handicapped, and (3) to set the course for a coordinated program for the handicapped in Arkansas.

CALIFORNIA

Course on Gastroenterology.—A course in Pathological Physiology of the Gastrointestinal Tract (limited to 30 students) will be offered on Wednesdays, 7:30-9:30 p.m., Sept. 12-Nov. 21 at the University of California Medical Center, Los Angeles, under the auspices of University Extension. The course chairman is Dr. Ralph R. Sonnenschein, associate professor of physiology. Requests for applications or information should be made to: Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, Los Angeles 24.

COLORADO

State Medical Meeting in Estes Park.—The 86th annual session of the Colorado State Medical Society will convene at the Stanley Hotel, Estes Park, Sept. 5-8 under the presidency of Dr. Robert T. Porter, Greeley. The opening session, Wednesday morning, will be devoted to the following program on "Future of Medical Practice":

Views of Labor on Medical Care, William A. Sawyer, Rochester, N. Y.
Supermarket Medicine, Francis T. Hodges, San Francisco.
A Physician's Concept of the Future of Medicine, Joseph D. McCarthy, Omaha.

Panel discussion will follow.

The topic for Thursday morning will be "Radioactive Isotopes in Diagnosis and Treatment." The incoming president, Dr. George R. Buck, Denver, will deliver his presidential address at 10 a.m. Dr. John H. Lawrence, Berkeley, Calif., will present "Diagnostic and Therapeutic Applications of Radioactive Isotopes and Nuclear Radiations in Medicine" immediately preceding the noon panel discussion of the morning presentations. A noon panel discussion will also be held after the Friday morning program on "The Patient, the Doctor, and the Hospital," which will include the following papers by out-of-state speakers:

The Hospital's Responsibility to the Patient, Mr. George Bubgee, New York City.
The Generalist, the Hospital, and the A. M. A., John S. DeTar, Milan, Mich.
The Specialist and the Hospital, Leland S. McKittrick, Brookline, Mass.
Accreditation, Its Purposes and Problems, Kenneth B. Babcock, Chicago.

A symposium on vertigo will conclude the Saturday session on neurological disorders. The sports events program includes bowling and fishing and a golf tournament, which is scheduled for Wednesday at the Estes Park Golf Club. Prizes will be awarded at the banquet on Friday. The women's auxiliary will meet concurrently.

CONNECTICUT

Symposium on Occupational Noise.—A conference will be presented Sept. 17 by the Yale University School of Medicine (department of surgery, section of otolaryngology, and department of public health, section of occupational health) and the Grace-New Haven Community Hospital (Hearing and Speech Center) in cooperation with the Liberty Mutual Insurance Company. The day-long session will end with panel discussions of noise and its measurement, effects of noise on man, legal and economic aspects of noise, a comprehensive conservation of hearing program, and prevention of hearing loss by engineering control. Physicians participating will include Dr. Aram Glorig Jr., Los Angeles, director of research, subcommittee of noise in industry, American Academy of Ophthalmology and Otolaryngology, and Dr. Meyer Fox, chief, ear, nose, and throat department, Mount Sinai Hospital, Milwaukee. The conference, planned for industrial executives, physicians, safety engineers, and others who are concerned with problems of occupational noise, will be held at Fitkin Amphitheater, Yale–New Haven Medical Center, 789 Howard Ave., New Haven. The fee, $15, includes luncheon. Only those who have registered in advance will be admitted. Further information may be obtained by writing to the Assistant Dean of Postgraduate Medical Education, Yale University School of Medicine, 333 Cedar St., New Haven 11.

GEORGIA

Society News.—The Georgia Society of Ophthalmology and Otolaryngology recently elected Dr. William L. Barton, Macon, president; Dr. F. Phinizy Calhoun Jr., Atlanta, vice-president; and Dr. Walter P. Rhyne, Albany, secretary-treasurer. The 1957 meeting will be held aboard ship, cruising from Charleston, S. C., to Nassau in the Bahamas, in April.

Meeting of Heart Association.—The eighth annual meeting and scientific sessions of the Georgia Heart Association will be held Sept. 14-15 at the General Oglethorpe Hotel, Savannah. Registration is free to all physicians, interns, and medical students. Out-of-state speakers and their presentations will include:

Robert P. Glover, director, Thoracic and Cardiovascular Research Laboratory, Presbyterian Hospital, Philadelphia, A Comparison of Long-Term Results in Mitral and Aortic Stenosis. Experimental and Clinical Results of Surgery for Mitral Insufficiency Employing Circumferential Constriction of the Mitral Annulus.
Stewart G. Wolf, professor and head of the department of medicine, University of Oklahoma School of Medicine, Oklahoma City, Preliminary Study of Lipoproteins and Life Adjustment in Coronary Occlusion. Personality and Hypertension.
William B. Schwartz, assistant professor of medicine, Tufts College Medical School, Boston, Electrolyte Problems in Congestive Heart Failure—Parts I and II.
Eugene A. Stead Jr., professor of medicine, Duke University School of Medicine, Durham, N. C., Low Fat Cookery. The Autonomic Nervous System and the Circulation.

MICHIGAN

Medical Alumni Conference.—The sixth triennial Medical Alumni Conference of the University of Michigan Medical School will meet in Ann Arbor, Sept. 27-29. A special program of scientific presentations, panels, and clinics has been arranged. The social program includes a banquet, special convocation of the medical school, and the Michigan–University of California at Los Angeles football game. Information on housing, program, and reservations can be obtained by writing to Dr. Albert C. Furstenberg, Dean, University of Michigan Medical School, Ann Arbor.

NEBRASKA

Crippled Children's Clinics.—Crippled children's clinics have been scheduled for Sept. 8 at the Senior High School Building, North Platte, and Sept. 22 at the Elks Club, Chadron.

University News.—Dr. John B. Davis, Omaha, who has just completed a four-year residency in surgery at the Research and Educational Hospitals, University of Illinois, Chicago, has been appointed a clinical assistant in surgery at his alma mater, the University of Nebraska College of Medicine, Omaha. Dr. Davis has become the third generation of his family to join the faculty

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

of the University of Nebraska College of Medicine. Both his father, Dr. Herbert H. Davis, and his grandfather, the late Dr. Byron B. Davis, have served as chairman of the department of surgery.

NEW YORK

Dr. Hoch Honored.—Dr. Paul H. Hoch, commissioner of mental hygiene for the state of New York, has been given the Man of the Year award of the International Rho Pi Phi Pharmaceutical Fraternity. The award cited Dr. Hoch for his "outstanding leadership in the research and treatment of mental illness, and his dedication to the welfare of its victims." Dr. Hoch joined the staff of the New York State Psychiatric Institute in 1943 and became director of the department of experimental psychiatry in 1948. He is also associate professor of clinical psychiatry at Columbia University College of Physicians and Surgeons, New York City, and an attending psychiatrist in the university's Psychoanalytic Clinic for Training and Research. Last year he received the Adolf Meyer Memorial award for his outstanding work in psychiatric research.

New York City

Personal.—Dr. Harold Brandaleone, assistant clinical professor of medicine (assigned to rehabilitation) at the New York College of Medicine, has been elected treasurer of the Alumni Federation of New York University, which in 1951-1955 he served as president. Dr. Brandaleone is president of the New York State Society of Industrial Medicine and medical director of the Third Avenue Transit System.——Dr. John H. Garlock, clinical professor of surgery at Columbia University College of Physicians and Surgeons and director of surgery at the Mount Sinai Hospital, is on an extended teaching tour of South America, where he is scheduled to give a series of lectures and hold didactic operative clinics in important medical centers. His itinerary includes Colombia, Chile, Peru, Argentina, and Brazil.——The American College of Surgeons awarded its third research scholarship to Dr. Sigmund A. Wesolowski, then assistant instructor in surgery at the State University of New York College of Medicine at New York City, Brooklyn, and a resident in surgery at Kings County Hospital. The scholarship, established in 1952 to support promising young surgeons who are interested in academic surgery and to promote surgical research, pays the recipient $20,000 over three years. On July 1, Dr. Wesolowski completed his residency training at Kings County Hospital and was promoted to instructor on the state university faculty, where he will devote full time to teaching and research. He hopes to spend a year in England during the period of the scholarship to study cardiovascular surgery under Sir Russell Brock at Guy's Hospital, London. During the war, as captain in the Army Medical Corps, Dr. Wesolowski did research in cardiovascular surgery at Walter Reed Army Hospital, Washington, D. C., for two years.——Drs. M. Ralph Kaufman, chief of psychiatry at Mount Sinai Hospital, and John A. Millet, who is affiliated with Presbyterian Hospital, have been named as consultants to the New York State Department of Mental Hygiene. Both men were charter members of the State Mental Hygiene Council and recently completed their terms of office after serving five years. Dr. Kaufman, who is clinical professor of psychiatry at the Columbia University College of Physicians and Surgeons, is a neuropsychiatric consultant to the surgeon general of the Department of the Army. He is the author of more than 30 papers on psychiatry and psychoanalysis.

NORTH CAROLINA

Meeting of Heart Association.—The annual meeting of the North Carolina Heart Association will be held at the Battery Park Hotel in Asheville Sept. 15-16 under the chairmanship of Dr. James V. Warren, Durham. The featured speaker will be Dr. Robert W. Wilkins, Boston, president of the Massachusetts Heart Association and vice-president of the American Heart Association. The theme of the session will be "Prevention of Coronary Heart Disease." A program on health education under the chairmanship of Dr. William L. Fleming of the University of North Carolina School of Medicine, Chapel Hill, has been scheduled for Saturday morning. All physicians are invited to attend this and other sessions of the association.

OHIO

Courses in Occupational Health for Nurses.—A series of courses in Occupational Health for Registered Nurses is offered by the Institute of Industrial Health of the University of Cincinnati College of Medicine to acquaint nurses already in industry, as well as other interested nurses, with current concepts and practices in the field of occupational health. The first lecture course, scheduled for the fall semester of 1956, will consist of 16 weekly evening sessions. The second lecture course, scheduled for the spring of 1957, will be concentrated in a period of one week, full time. The faculty for both courses, to be held at the college of medicine, will be composed of members of the college, representatives of the nursing profession, management, and other recognized authorities in this field. The registration fee is $25. For additional information write: Secretary, Institute of Industrial Health, College of Medicine, Cincinnati 19.

UTAH

State Medical Meeting in Salt Lake City.—The 61st annual meeting of the Utah State Medical Association will convene at the Hotel Utah, Salt Lake City, Sept. 5-8, under the presidency of Dr. Ralph O. Porter, Logan. At the president's banquet for doctors and their wives Friday evening, Dr. Dwight H. Murray, Napa, Calif., President of the American Medical Association, will have as his subject "The Physician and His Hospital." Other guest speakers and their first presentations will include:

Mark M. Ravitch, Baltimore, Surgical Approach to Ulcerative Colitis.
Harris B. Shumacker Jr., Indianapolis, Management of Abdominal Aortic Aneurysms.
Ralph K. Ghormley, Rochester, Minn., Present Status of Surgery of the Hip Joint (accompanied by film).
Lowell A. Rantz, San Francisco, Modern Management of Rheumatic Fever.
Russell R. de Alvarez, Seattle, Bleeding of Late Pregnancy.
Mr. Harry Becker, Chicago, Voluntary Prepayment Insurance at the Crossroads.
Henry M. Weyrauch Jr., San Francisco, Modern Treatment of Urinary Infection.
Robert A. Aldrich, Portland, Ore., Present Status of Tuberculosis in Childhood.
Hugh F. Hare, Los Angeles, Radiation Treatment of Carcinoma of the Breast.
Charles R. B. Blackburn, Sydney, Australia, Contraindications for Adrenalectomy in Carcinomatosis—A Physician's Appraisal.
Howard P. House, Los Angeles, The Doctor's Responsibility to the Hearing Handicapped.

Morning sessions will open at 8 a. m. with motion pictures. On Thursday at 10:50 a. m. Dr. Russell M. Nelson, Salt Lake City, will serve as moderator for a symposium on intestinal obstruction. Panel discussions on surgery and on obstetrics and pediatrics are scheduled for noon luncheon meetings. The Friday symposium (10:50 a. m.), "Current Topics in Internal Medicine," will be sponsored by the department of medicine, University of Utah School of Medicine, Salt Lake City, and will have as moderator Dr. Maxwell M. Wintrobe. Noon luncheon discussions Friday will be on internal medicine, pediatrics, and urology. At 3:20 p. m. the specialty groups will have panel discussions with guest speakers participating. The women's auxiliary will meet Sept. 6-7.

VERMONT

Personal.—Dr. Bernis D. Colby, Sudbury, honorary member of the Rutland County and the Vermont State Medical societies, received the honorary degree of doctor of science at the annual commencement of the University of Vermont, Burlington.

Symposium on Electrolytes.—A Symposium on Electrolytes and the Circulation, open to all interested persons, will be held in Burlington, Sept. 8-10, under the sponsorship of the Vermont Heart Association and the University of Vermont College of Medicine, Burlington. Topics will include the electrolyte metabolism in congestive heart failure and the role of electrolytes in myocardial metabolism, the electrocardiogram and cardiac arrhythmias, and vascular reactivity and hypertension. Further information can be obtained from Dr. Eugene Lepeschkin, University of Vermont College of Medicine, Burlington.

WISCONSIN

Head of Orthopedic Surgery.—Dr. Walter P. Blount, chief of orthopedics at Milwaukee Children's Hospital, has been appointed clinical professor and director of the department of orthopedic surgery at Marquette University School of Medicine, succeeding the late Dr. Herman Schumm.

"Dr. Kate" Fund.—A special Doctor Kate Newcomb Memorial fund has been established by the Wisconsin chapter of the Arthritis and Rheumatism Foundation. The fund will be used to purchase a hydrotherapy tank for Lakeland Memorial Hospital in Woodruff. The chapter will also present a 5-ft. portrait of Dr. Kate to the hospital, which she built with penny contributions. Because of her unexpected death, the chapter canceled a testimonial dinner. Those who planned to attend the testimonial have been asked to contribute to the memorial fund.

Personal.—Dr. John S. Horning, Milwaukee, left for Costa Rica in August to take a year of language study, preparatory to setting up a medical clinic among the Quechua Indians near Quito, Ecuador.—Dr. Harold M. Coon, superintendent of the University Hospitals, Madison, since 1941, has been appointed administrator of Milwaukee County Hospital as of Sept. 1, to succeed Dr. Harry W. Sargeant, who will retire Nov. 27. Dr. Coon, who serves also as professor of hospital administration at the University of Wisconsin Medical School, is the son of the late Dr. John W. Coon, who was superintendent of the county hospital for about one year.

Circuit Teaching Programs.—The council on scientific work of the State Medical Society of Wisconsin (in cooperation with the state board of health, the medical schools of the University of Wisconsin in Madison and Marquette University in Milwaukee, the Wisconsin Academy of General Practice, the Wisconsin Heart Association, Wisconsin Anti-Tuberculosis Association, and the Wisconsin division of the American Cancer Society) has scheduled a series of 12 circuit teaching programs. During September these clinics will be held at the St. Francis Hospital, La Crosse, Sept. 11; Sacred Heart Hospital, Eau Claire, Sept. 12; and St. Mary's Hospital, Superior, Sept. 13. The faculty will consist of Drs. John Z. Bowers, Madison, arthritis; George R. Barnes, Iowa City, pediatrics; James E. Conley, Milwaukee, surgery; and Donald M. Ruch, Milwaukee, dermatology. The registration fee, which covers a full afternoon and evening of instruction and dinner, is $6. Participants are requested to attend both sessions, as the meetings will be correlated, and those who attend both sessions will receive credit for Academy of General Practice membership requirements. Requests for reservations should be sent to the State Medical Society of Wisconsin, P. O. Box 1109, Madison.

GENERAL

Meeting on Instrumentation.—The Instrument Society of America will hold its 11th annual meeting in the new Coliseum, New York City, Sept. 17-21. The program lists presentations on recent developments in medical and biological instrumentation, including Photo Counters for Chromatographic Densitometry in the U. V. Region, Electrical Method for Objective Determination of Blood Pressure Utilizing Standard Electrocardiographs, New Artificial Respiration Machine, Heat Flow Transducer with Indicating and Recording Equipment for Physiological and Biochemical Research, Automatic Particle and Bacterial Colony Counter, Counter-Current Distribution Apparatus Using 3-Phase Solven System, Low Frequency Analyzers in Electroencephalography, and Research on Mechano-Electronic Transducer Blood Pressure Manometers.

Nuclear Scientists Invite Papers.—The American Nuclear Society invites the submission of papers for its meeting Dec. 10-12 in the Sheraton-Park Hotel, Washington, D. C. The society was formed about 18 months ago in response to a demand for a single organization encompassing all the professional disciplines of science and engineering applying to the atomic energy field. Authors desiring to present papers at the December meeting are requested to send titles and estimates of presentation time to L. D. O. King, Ph.D., Los Alamos Scientific Laboratory, P. O. Box 1663, Los Alamos, N. Mex., by Oct. 1. Abstracts of the papers must be received not later than Nov. 1. The society publishes its own journal, *Nuclear Science and Engineering.* Contributors to the journal should send their papers to J. G. Beckerley, Ph.D., P. O. Box 2175, Houston, Texas.

Conference on Clinic Organization.—A symposium, "Policies and Methods of Determining Income of Physicians," scheduled for Friday noon, will be a program feature of the West Coast Conference on Financial and Human Problems of Clinic Organization in Santa Barbara, Calif., Sept. 21-23. According to the University of California at Los Angeles School of Medicine, School of Public Health, and University of California Extension, which are planning the conference in cooperation with the National Association of Clinic Managers, Western Section, such problems as financial insurance and legal aspects of clinic management will be considered. Numerous intensive study groups, as well as a tour of local clinics and the new campus of the University of California, are planned. Registration for the conference is being accepted at the offices of University of California Extension, Los Angeles 24. Fee for the session is $50.

Conference on Pharmacotherapy in Mental Illness.—A conference on the evaluation of research on pharmacotherapy in mental illness will be held at the Hotel Statler in Washington, D. C., Sept. 21-22 under the joint sponsorship of the division of medical sciences of the National Academy of Sciences—National Research Council, the National Institute of Mental Health, and the American Psychiatric Association, with Dr. Ralph W. Gerard, Chicago, as leader. The conference will be based on presentations of several *ad hoc* working groups, whose reports on the methodological, theoretical, and administrative problems involved in evaluating tranquilizing and other drugs, both at preclinical and clinical levels, will be reviewed in closed committee sessions during the two preceding days. Those interested in attending the conference should write to the executive secretary of the project, Dr. Jonathan O. Cole, National Academy of Sciences, 2101 Constitution Ave., Washington 25, D. C.

Northwest Association of Occupational Medicine.—The Northwest Association of Occupational Medicine was recently organized, with Dr. Eugene P. Owen of Portland, Ore., as president; Dr. Wilhelm J. Sittner, Portland, Ore., secretary; Dr. Charles M. McGill, Tacoma, Wash., vice-president; and Dr. Bradford C. Scudder of Hanford, Calif., and Dr. Forrest E. Rieke, Portland, Ore., board members. The association will hold its first technical meeting Sept. 9, the day before the opening of the third annual Northwest Industrial Health Conference. Speakers at the technical meeting will include Drs. Hedwig S. Kuhn, Hammond, Ind.; Jermyn F. McCahan, Boston; R. Christopher Leggo, Palo Alto, Calif.; Roger Anderson, Seattle; William J. McNamara, New York; and Mr. William Lawrence, attorney from Seattle. The meeting will be open to all interested physicians, nurses, attorneys, insurance representatives, and lay officials of health agencies. The association, with membership in Oregon, Washington, Idaho, British Columbia, and Alaska, is open to qualified physicians whose practices are partly or entirely devoted to industrial medicine or surgery.

Borden Award in Nutrition.—Nominations are solicited for the 1957 award and gold medal made available by the Borden Company Foundation, Inc. The American Institute of Nutrition will make this award in recognition of distinctive research by investigators in the United States and Canada that has emphasized the nutritive significance of the components of milk or of dairy products. The award will be made primarily for the publication of specific papers during the previous calendar year, but the jury of award may recommend that it be given for important contributions made over a more extended period of time. Nominations, which may be made by anyone, should include the name of the award for which the candidate is proposed and a statement as to the basis of the nomination (this may include a pertinent bibliography, but reprints are not required). To be considered for the 1957 award, five copies of all documents, including seconding statements, must be sent before Jan. 1, 1957, to the chairman of the nominating committee, Cosmo G. Mackenzie, Sc.D., Department of Biochemistry, University of Colorado School of Medicine, 4200 E. Ninth Ave., Denver 7.

Essay Contest in Dermatology.—The American Dermatological Association offers a series of awards for original work not previously published and relative to some fundamental aspect of dermatology or syphilology: $500, $400, $300, and $200 for first, second, third, and fourth places respectively. Manuscripts, not exceeding 10,000 words, typed in English with double spacing and ample margins as for publication, together with illustrations, charts, and tables, all of which must be in triplicate, are to be submitted not later than Nov. 15 to Dr. J. Lamar Callaway, Secretary, American Dermatological Association, Duke Hospital, Durham, N. C. Papers should be submitted under a nom de plume and should be accompanied by a plain sealed envelope bearing the nom de plume and the full name and address of the author. Competition is open to scientists generally—not exclusively to physicians. The results will be announced before Jan. 1, 1957. The candidate winning first award may be invited to present his paper before the annual meeting of the American Dermatological Association with expenses paid, in addition to the award. Further information regarding this essay contest may be obtained by writing to the secretary of the association.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

Congress on Clinical Chemistry.—The first International Congress of Clinical Chemistry will convene Sept. 9-14 at the Hotel Barbizon-Plaza, New York, under the auspices of the American Association of Clinical Chemists. A session on electrolytes, dedicated to the memory of Dr. John P. Peters, author of "Quantitative Clinical Chemistry," is planned for Monday morning. Other topics of the congress include: lipids and cholesterol, blood and bile pigments, standardization of clinical chemical measurements, and enzymes and vitamins. A symposium on proteins is scheduled for Friday morning. The program includes a reception Monday evening and a dinner Tuesday evening. Information and registration forms may be obtained from the congress secretary, John G. Reinhold, Ph.D., 711 Maloney Bldg., University of Pennsylvania, Philadelphia 4. Membership applications should be sent with $7.50 to the secretary. A week-end tour of Philadelphia and Washington has been planned especially for visitors from outside the country; others may participate, if space is available. The complete cost (excluding tips) will be $35 to $40. The tour will leave New York Saturday morning, spend Saturday in Philadelphia, proceed to Washington Sunday, and, after sight-seeing, visit the National Institutes of Health in Bethesda, Md., and other laboratories, if time permits, on Monday. It will end in Atlantic City, N. J., Monday evening. Those interested should inform Dr. Harry Goldenberg, Hillside Hospital, Glen Oaks, N. Y. Tickets will be on sale at the congress.

Memorial Hospitals Dedicated.—On June 2, 150 years after the initiation of coal mining in the United States, the following memorial hospitals were dedicated by John L. Lewis, chairman of the board of trustees, United Mine Workers of America Welfare and Retirement Fund, "in memory of those men who died without hospitals": Harlan (Ky.) Memorial Hospital, McDowell (Ky.) Memorial Hospital, Middlesboro (Ky.) Memorial Hospital, Wise (Va.) Memorial Hospital, Hazard (Ky.) Memorial Hospital, Whitesburg (Ky.) Memorial Hospital, Beckley (W. Va.) Memorial Hospital, Man (W. Va.) Memorial Hospital, Pikeville (Ky.) Memorial Hospital, and Williamson (W. Va.) Memorial Medical Center. The 10 hospitals, forming a three-state network (The Journal, March 27, 1954, pages 1101-1103; June 18, 1955, page 571) were "consecrated to the care of the sick, the prevention of disease, and the preservation of the health of the people, as far as they can reach. They will serve as the nucleus and inspiration for the development of other vital services around them." Physicians who addressed the meeting included Dr. Elmer Hess, Erie, Pa., then President of the American Medical Association; Dr. Warren F. Draper, Washington, D. C., executive medical officer, United Mine Workers of America Welfare and Retirement Fund; Dr. Frederick D. Mott, Washington, D. C., medical administrator, Miners Memorial Hospital Association; and Dr. Howard A. Rusk, chairman of the department of rehabilitation and physical medicine, New York University College of Medicine, New York City.

Research Grants and Fellowships in Cardiology.—The Chicago Heart Association, 69 W. Washington St., Chicago 2, offers grants-in-aid for the fiscal year, July 1-June 30, that may be renewed on application and annual review. Completed application is due Nov. 1, to be effective the following July 1. For information and forms write to: Chicago Heart Association, Attention: Program Coordinator.——The American Heart Association, 44 E. 23rd St., New York 10, provides (1) established investigatorships ($6,000-$9,000 a year) for one to five years, subject to annual review (application deadline, Sept. 15); (2) grants-in-aid for equipment, technical assistance, and supplies to experienced scientists working on approved projects for one to five years (application deadline, Nov. 1); and (3) research fellowships ($3,500-$5,600 a year) for one to two years to young scientists to train in research under experienced supervision (application deadline, Sept. 15). For information write to: Medical Director, American Heart Association.——The National Institutes of Health, Division of Research Grants, Bethesda 14, Md., awards (1) research grants for any research directly or indirectly related to problems of health or disease, without limitation on the size of a grant, the number of grants, the total amount awarded in research grants that may be made to any one investigator or any one institution in a fiscal year, or requirement of matching research grant funds; (2) research fellowships, including predoctoral research fellowships ($1,400; first year of graduate study $1,600, terminal year $1,800 plus $350 for each dependent; a minimum basic tuition allowance); (3) postdoctoral research fellowships ($3,400 a year plus $350 for each dependent; plus $300 on renewal for second and third year; plus $500 to the institution to defray expenses); and (4) special research fellowships, determined by the surgeon general at the time of the award. For information and forms write directly to the Division of Research Grants, National Institutes of Health, Bethesda 14, Md.—The Life Insurance Medical Research Fund, 345 E. 46th St., New York 17, offers (1) postdoctoral fellowships for research training in cardiovascular function or disease, with consent of an experienced investigator to serve as a supervisor (minimum $3,800 per year with allowances for dependents; an increase of $300 on renewal; $500 to institution to help defray expenses) for 12 months beginning on any one of the following dates: July 1, Aug. 1, Sept. 1, Oct. 1, with complete application for 1957-1958 fellowship year due Oct. 15, 1956, and (2) grants-in-aid for research broadly concerned with cardiovascular disease or function (usual range: $1,000-$15,000 a year), with complete applications for 1957 grants, including renewals, due Nov. 1, 1956. For information and forms, sponsors should correspond with: Dr. Francis R. Dieuaide, New York, Scientific Director.

FOREIGN

Meeting on Industrial Medicine.—The Austrian Society for Industrial Medicine announces that the third Austrian Congress on Industrial Medicine will be held in Vienna, Oct. 1-4, to discuss "Success by Early Diagnosis and Preventive Measures." The subjects will include:

> Medical examination for fitness and ensuing selection; examinations with regard to employment or reemployment.
> Prevention of poisoning by proximate causes (technical expedients)
> Prevention of illness (periodical examination and transfer to another post, medical prophylaxis).
> Prevention of damages caused by prolonged work under conditions detrimental to health (violent motion and draught, prevention of accidents).
> Economic value and advantages of preventive measures taken by industrial medicine.

Persons interested in attending or in reading papers on these subjects may apply to the Organizing Secretary, Dr. Ch Frieberger, Austrian Society for Industrial Medicine, Kinderspitalgasse 15, Vienna, Austria. There is no registration fee.

Congress on Speech and Voice Therapy.—The 10th Congress of the International Association of Logopedics and Phoniatrics will convene in Barcelona, Spain, Sept. 3-7. Reports will be presented on "Studies of the Onset and Development of Stuttering," "Neurology and Speech and Language Disorders," "Nonverbal Tests of Intelligence and Maturity," and "Amusia." Further details may be obtained from the Organizing Secretary. Dr. J. Perello, Provenza, 319, Barcelona (9), Spain.

Congress on the History of Science.—The eighth International Congress for the History of Science will convene in Florence, Italy, Sept. 3-9 under the auspices of the International Academy and the International Union for the History of Science. The program will include a session on the history of chemistry and pharmacy and a session on the history of medicine and biology. Information may be obtained from the Office of the Secretary General, Dr. M. L. Bonelli, Instituto di Ottica, Arcetri, Florence, Italy.

Congress on Dietetics.—The second International Congress of Dietetics will be held in Rome, Italy, Sept. 10-14, in the Congress Palace of Esposizione Universale Roma. The Italian Dietetic Association will be the host. The program will include recent findings of nutritional research, methods of education in nutrition, principles and problems of feeding large numbers of people, and problems of training dietitians. All persons interested in nutrition and dietetics may attend sessions of the congress on payment of the registration fee. Participants in the program will include Charlotte M. Young, Ph.D., professor of medical nutrition, Cornell University, Ithaca, N. Y., who will contribute to a symposium on obesity; Alice H. Smith, chief nutritionist of the Michigan Department of Health, who will speak on the "Educational and Social Aspects of Malnutrition in Relation to Tuberculosis"; and Jean Mayer, Ph.D., associate professor of nutrition, Harvard University, Boston, who will be a member of the discussion group concerned with "Obesity: A Nutritional Problem of Increasing Importance and Its Relationship to Economics, Social and Health Conditions." An entire morning will be devoted to programs on child feeding. Information on the congress and postcongress tours may be obtained from the American Dietetic Association, 620 N. Michigan Ave., Chicago 11.

CORRECTION

Dr. Huebner's Name Misspelled.—In the leading article in The Journal of Aug. 18, 1956, on page 1521 and on The Journal cover, the third author's name was misspelled and should read "Robert J. Huebner, M.D., Bethesda, Md."

EXAMINATIONS AND LICENSURE

American Board of Dermatology: *Oral* St Louis, Oct 12-15 Final date for filing applications was April 1. Sec, Dr. B. M Kesten, One Haven Ave, New York 32.

American Board of Internal Medicine. *Written* Oct. 15, 1956 Final date for filing application was May 1. *Oral Examinations in 1956* New York City, Sept. 21-25. Final date for filing application was April 1. Exec Sec., Dr. William A. Werrell, 1 West Main St, Madison 3, Wis

American Board of Neurological Surgery Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time Sec., Dr. Leonard T Furlow, Washington University School of Medicine St Louis 10

American Board of Obstetrics and Gynecology *Part I* 1957 Applications for certification for the 1957 examinations are now being accepted Candidates making new application or requesting the reopening of an application must do so before Oct. 1, 1956. Applications are to be accompanied by a list of hospital admissions. *Written. Part I* Various cities of the United States, Canada and military centers outside the continental United States, Feb. 1. Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology. *Practical Examination* St. Louis, Oct. 20-24. *Written* Jan. 21, 1957. Applications must be filed before July 1, 1956. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery *Oral Part II* Chicago, January 1957. Final date for filing application is Aug 15. Sec, Dr. Sam W Banks, 116 South Michigan Ave., Chicago 3

American Board of Otolaryngology. *Written and Oral.* Chicago, Oct. 8-11 Sec., Dr Dean M. Lierle, University Hospitals, Iowa City

American Board of Pathology. *Written for Pathological Anatomy and Clinical Pathology*, Oct. 4-6. Final date for filing application is Sept 1 Sec, Dr Edward B. Smith, 1040-1232 W Michigan St., Indianapolis 7.

American Board of Pediatrics *Oral, Part II* New York City, Oct. 12-14, and San Francisco, Dec. 7-9. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa

American Board of Plastic Surgery Miami, Oct. 17-19. Corres. Sec, Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine. *Oral and Written Public Health* Philadelphia, Nov. 8-10. Sec, Dr. Ernest L Stebbins, 615 N. Wolfe St., Baltimore, Md

American Board of Proctology. *Oral and Written* Philadelphia, Sept. 29 Final date for filing application was June 28 Sec., Dr Stuart T. Ross, 520 Franklin Ave, Garden City, N. Y

American Board of Psychiatry and Neurology *Oral* New York, Dec. 10-11 and New Orleans, Mar. 18-19. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W, Rochester, Minn

American Board of Radiology. Los Angeles, Sept. 30-Oct 4. Final date for filing application was June 1. Sec., Dr. B R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery. *Part I.* Various Centers Throughout the United States and in Certain Military Centers Abroad, Oct. 31. *Part II.* Buffalo, Sept. 24-25, Chicago, Oct. 15-16, New Haven, Nov. 19-20, Kansas City, Kan, Dec. 10-11, Los Angeles, Jan. 14-15; San Francisco, Jan. 17-18, Houston, Feb. 18-19, Nashville, Mar. 11-12, Boston, April 8-9, and New York, June 10-11.

American Board of Urology: February 1957. Sec., Dr. William Niles Wishard, 1711 N. Capital Ave., Indianapolis 7.

Board of Thoracic Surgery: *Written* Various centers throughout the country, Sept. 7. Final date for filing applications was July 1. A subsequent written examination will be held in February 1957, and the closing date for registration is Dec. 1, 1956. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

DEATHS

Ruth, Henry Swartley ⊕ Penn Valley, Pa.; born in Philadelphia Aug. 12, 1899; Hahnemann Medical College and Hospital of Philadelphia, 1923; emeritus professor of anesthesiology at his alma mater, where he was clinical professor of anesthesia from 1933 to 1940 and later professor and head of the department of anesthesiology; specialist certified by the American Board of Anesthesiology, of which he was at one time vice-president and president; in 1918 served in the Student Army Training Corps; director of courses in anesthesiology for the U. S. Army and Navy during World War II; president of the American Society of Anesthesiology in 1938, vice-president the previous year, and served for many years on its board of directors, in 1952 was presented with the Distinguished Service award of the American Society of Anesthesiologists; past-president of the Philadelphia Society of Anesthesiology and the Pennsylvania Society of Anesthesiology; formerly vice-president of the American Society of Regional Anesthesia; member of the International Anesthesia Research Society and the World Medical Association; fellow of the International College of Surgeons, Secretary, Section on Miscellaneous Topics, Section on Anesthesia, American Medical Association, 1939-1940; chief, division of anesthesia at the Philadelphia General Hospital from 1933 to 1940 when he became consulting anesthetist; civilian consultant for the U. S. Naval Hospital in Philadelphia from 1948 to 1952; chief, anesthetic service, West Jersey Homeopathic Hospital in Camden, N. J., 1941-1942; for many years on the staffs of the Hahnemann and St. Luke's and Children's hospitals in Philadelphia; author of section on anesthetics, revision service volume, "Cyclopedia of Medicine," in 1944, and section on regional anesthesia, Bancroft's "Operative Surgery," in 1941; associate editor of anesthesia subjects in "Cyclopedia of Medicine, Surgery, Specialties," from 1939 to 1952; first editor of *Anesthesiology* and served in that capacity until his retirement last year, remaining as editor emeritus; on the advisory board of the *American Journal of Surgery*; died June 7, aged 56, of cerebral concussion with edema and hemorrhage, as the result of a fall.

Christie, Arthur Carlisle ⊕ Crescent City, Fla.; born in West Sunbury, Pa., Dec. 29, 1879; University of Wooster Medical Department, Cleveland, 1904; specialist certified by the American Board of Radiology; member and past-president of the Medical Society of the District of Columbia, American Roentgen Ray Society, and the American College of Radiology, receiving its Gold medal in 1953; in 1937 elected president of the Fifth International Congress of Radiology, honorary fellow of the British Faculty of Radiologists; member of the American Radium Society; fellow of the International College of Surgeons and the American College of Physicians; formerly professor of operative surgery and roentgenology at the Army Medical School, Washington, D. C., professor of radiology, George Washington University School of Medicine in Washington, D. C., and professor of clinical radiology at the Georgetown University School of Medicine in Washington, D. C.; a president of the board of trustees of the American University in Washington, D. C.; on the board of honorary consultants, Army Medical Library; received the second Dr. Frank E. Gibson Award in recognition of "meritorious contributions to medical science"; formerly member of the Committee on the Costs of Medical Care; veteran of World War I; served as consultant in radiology to the U. S. Army, the Veterans Administration, and the National Research Council; from 1924 to 1929 editor of the *American Journal of Roentgenology and Radium Therapy*, author of "Economic Problems of Medicine" and other books, died June 22, aged 76.

Wahl, Harry Roswell ⊕ Kansas City, Kan.; born in Minnesota City, Minn., in 1886; Johns Hopkins University School of Medicine, Baltimore, 1912; professor of pathology at the University of Kansas School of Medicine, where he was dean for many years; specialist certified by the American Board of Pathology; member of the American Association of Pathologists and Bacteriologists and the College of American Pathologists; consulting pathologist at Veterans Administration Hospital in Excelsior Springs, Mo., Bethany and St. Margaret's hospitals; in recognition of his services, the Kansas Board of Regents voted recently to change the name of the Medical Science Building at the Medical Center to Wahl Hall; for many years pathologist and superintendent of the University of Kansas Hospitals; died in the University of Kansas Medical Center June 18, aged 70, of carcinoma of the urinary bladder.

Barnett, Irving Francis ⊕ Chicago; born in Chicago in 1891; University of Illinois College of Medicine, Chicago, 1913; associate clinical professor of ophthalmology at Stritch School of Medicine of Loyola University; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology; fellow of the American College of Surgeons; awarded the Victoria Cross for medical service in the British Army during World War I; for two years county jail physician; senior ophthalmologist at the Henrotin Hospital, where he died June 26, aged 64, of cerebral thrombosis.

Hynes, Frank Joseph ⊕ New York City; born in New York City Oct. 16, 1908; University and Bellevue Hospital Medical College, New York City, 1933; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological and Otological Society, American Trudeau Society, and the American College of Allergists; fellow of the International College of Surgeons and the American College of Surgeons; served on the faculty of Cornell University Medical College, on the staffs of the Manhattan Eye, Ear and Throat Hospital and the New York Hospital; died June 7, aged 47.

Berman, William ⊕ White Plains, N. Y.; born in Rochester July 22, 1900, Cornell University Medical College, New York City, 1925; certified by the National Board of Medical Examiners; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychoanalytic Association, American Psychiatric Association, Association for Research in Nervous and Mental Diseases, and the American Psychopathological Association; on the staffs of the Grasslands Hospital in Valhalla, St. Agnes Hospital in White Plains, and the United Hospital in Port Chester; died March 12, aged 55.

Durkin, Harry Anthony ⊕ Peoria, Ill.; Harvard Medical School, Boston, 1915; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served as a member and president of the city board of health; past-president of the Illinois Heart Association and the Peoria Heart Association; veteran of World War I; past-president of the board of the Peoria Municipal Tuberculosis Sanitarium; on the staffs of the Methodist Hospital of Central Illinois and St. Francis Hospital, where he died May 20, aged 65, of nephrosclerosis and general arteriosclerosis.

Barbour, Guy William ⊕ West Stewartstown, N. H.; Kentucky School of Medicine, Louisville, 1908; died May 10, aged 73, of heart disease.

Barbour, William Jay ⊕ Shell Rock, Iowa; State University of Iowa College of Medicine, Iowa City, 1947; formerly an officer in the U. S. Air Force Reserve; died in the Veterans Administration Hospital, Iowa City, May 8, aged 32, of toxic myocarditis.

Rowan, Henry Madison ⊕ Trenton, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1920; director of the department of obstetrics and attending obstetrician at the Mercer Hospital, where he died April 12, aged 61, of carcinoma of the esophagus with metastasis to the brain.

Rummage, Leland Charles, Nanticoke, Pa.; Medico-Chirurgical College of Philadelphia, 1913; a member of the board of education; served as vice-president and president of the First National Bank; president of the board of the Retreat State Hospital in

---

⊕ Indicates Member of the American Medical Association

Hunlock Creek, where he was consultant; chairman of the board of Nanticoke State Hospital, where he died May 29, aged 69, of rupture of the arch of the aorta, atherosclerosis, and hypertension.

Ruskin, Thomas Morris, Wapakoneta, Ohio; Ohio State University College of Medicine, Columbus, 1954; interned at the Mercy Hospital in Springfield; veteran of World War II; on the staff of St. Rita's Hospital in Lima; died April 28, aged 29, of melanosarcoma.

Safley, Agnes Isabel ⊕ Cedar Rapids, Iowa; State University of Iowa College of Medicine, Iowa City, 1904; on the staff of St. Luke's Methodist Hospital, where she died April 26, aged 80, of myocardial infarction.

Sangmeister, Henry John Augustus ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1916; fellow of the American College of Surgeons; served on the faculty of his alma mater; veteran of World War I; on the staffs of St. Joseph's, St. Agnes, and St. Vincent's hospitals; for many years on the staff of the Philadelphia General Hospital; died in the Lankenau Hospital May 5, aged 66, of intestinal obstruction.

Santos, Pedro Martir ⊕ Chicago; Meharry Medical College, Nashville, Tenn., 1914; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the International College of Surgeons; for many years on the staff of Provident Hospital; died in Milwaukee June 25, aged 69.

Saylor, Melvin Alvin, North Wales, Pa.; Jefferson Medical College of Philadelphia, 1915; emeritus professor of physiological chemistry at Temple University School of Medicine in Philadelphia; served on the faculty of his alma mater; member of the American Chemical Society, American Association of University Professors, and the American Association for the Advancement of Science; died in the North Penn Hospital, Lansdale, April 11, aged 81, of heart disease.

Scanlan, Peter Lawrence, Prairie du Chien, Wis.; Rush Medical College, Chicago, 1891; died Feb. 29, aged 93, of generalized arteriosclerosis, diabetes mellitus, and carcinoma of the prostate.

Schell, Warren W., Jacksonville, Fla.; Meharry Medical College, Nashville, Tenn., 1905; on the staff of the Brewster Hospital, died April 23, aged 76, of myocardial degeneration.

Schlesinger, Jacob ⊕ Hammond, Ind.; Chicago College of Medicine and Surgery, 1914; member of the American Academy of General Practice; at one time secretary of the Lake County Medical Society; veteran of World War I; vice-president of the active staff of St. Margaret Hospital, where he died March 14, aged 64, of acute coronary occlusion.

Schmitt, Gustav, Milwaukee; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; died in St. Mary's Hospital April 7, aged 83, of cardiac infarction.

Schram, David Leo ⊕ Chicago; Northwestern University Medical School, Chicago, 1900; on the staff of Michael Reese Hospital, where he died April 29, aged 79, of acute myocardial infarction.

Schub, Rosa Brind, Trenton, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1931; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; on the staff of the New Jersey State Hospital, where she died April 10, aged 57, of coronary occlusion.

Schwartz, Alfred John Charles ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; member of the Missouri State Medical Association; veteran of World War I; died in the American Hospital June 3, aged 76, of carcinoma of the stomach.

Scott, Dwight Ferdina, Sault Sainte Marie, Mich.; Northwestern University Medical School, Chicago, 1934; on the staff of the Chippewa County War Memorial Hospital, where he died May 2, aged 48, of massive gastric hemorrhage.

Scott, Francis Joseph ⊕ Waterford, N. Y.; Albany (N. Y.) Medical College, 1905; formerly health officer; served on the staffs of the Cohoes (N. Y.) Memorial Hospital and the Leonard Hospital in Troy, where he died April 12, aged 73, of cerebral hemorrhage.

Scott, Henry, New York City; University of the City of New York Medical Department, New York City, 1895; on the staffs of the Harlem and St. Luke's hospitals, and New York Hospital–Cornell Medical Center; died in Nashville, Tenn., May 8, aged 84, of arteriosclerotic heart disease.

Senseny, Herbert Milford ⊕ Fort Wayne, Ind.; Johns Hopkins University School of Medicine, Baltimore, 1910; veteran of World War I; past-president of the Allen County Medical Society; served as president of the medical staff at St. Joseph Hospital, where he died March 12, aged 71, of coronary occlusion.

Seward, Frederic Henry, Madison, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; an associate member of the American Medical Association; on the staffs of the All Souls and Morristown Memorial hospitals in Morristown; died in Maplewood May 10, aged 78.

Sessoms, M. Perry, Savannah, Ga.; Leonard Medical School, Raleigh, N. C., 1906; died May 16, aged 75, of coronary occlusion and arteriosclerosis.

Shaweker, Max ⊕ Canton, Ohio; Northwestern University Medical School, Chicago, 1914; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; veteran of World Wars I and II; served on the board of education in Dover; chief pathologist at the Mercy Hospital; formerly on the staff of the Union Hospital in Dover; died April 18, aged 67.

Sheid, Zachariah T., Norfolk, Ark. (licensed in Arkansas in 1903); died in Mountain Home, April 26, aged 82.

Short, William Henry ⊕ Captain, U. S. Navy, retired, La Jolla, Calif.; Georgetown University School of Medicine, Washington, D. C., 1904; entered the U. S. Navy May 20, 1907; retired June 30, 1936; died in the U. S. Naval Hospital, San Diego, May 15, aged 75, of a heart attack.

Siddall, William Glenn, Alliance, Ohio; Western University Faculty of Medicine, London, Ontario, Canada, 1915; fellow of the American College of Surgeons; on the staff of the Alliance City Hospital; died April 13, aged 65.

Sims, William Scott ⊕ Hamtramck, Mich.; Meharry Medical College, Nashville, Tenn., 1932; interned at the Provident Hospital and Free Dispensary in Baltimore; veteran of World War II; on the staffs of the Kirwood General and Trinity hospitals in Detroit, died June 11, aged 50, of coronary occlusion.

Sisler, Franklin Herbert ⊕ Bristow, Okla.; College of Physicians and Surgeons, Baltimore, 1910; on the staff of the Bristow Memorial Hospital, where he died April 7, aged 68, of cerebrovascular accident.

Small, Harold Ernest ⊕ Fullerton, Calif.; University of Vermont College of Medicine, Burlington, 1915; fellow of the American College of Surgeons; for many years practiced in Augusta, Maine, where he was on the staff of the Augusta General Hospital; served on the staff of the Cary Memorial Hospital in Caribou, Maine; on the staff of St. Joseph Hospital in Orange, where he died May 17, aged 69, of coronary occlusion and posterior myocardial infarct.

Smith, Charles Russell, Harrisburg, Ohio; Starling Medical College, Columbus, 1894; for many years president of the Pleasant Township School Board; served on the staff of the Mount Carmel Hospital in Columbus; died April 6, aged 84, of injuries received in an automobile accident.

Smith, Joseph G. ⊕ Bartlesville, Okla.; Medico-Chirurgical College of Kansas City, Mo., 1903; died in the Jane G. Phillips Memorial Hospital May 7, aged 85.

Smith, Leighton Alexander ⊕ Quitman, Ga.; University of Louisville (Ky.) Medical Department, 1915; died in the John D. Archbold Memorial Hospital in Thomasville May 7, aged 64, of myocardial infarction.

Smith, Rockwell Emerson ⊕ Henderson, Ky.; University of Virginia Department of Medicine, Charlottesville, 1910; died in the Methodist Hospital April 30, aged 72, of cerebral thrombosis.

Smith, William Morgan, Boston; Tufts College Medical School, Boston, 1904; died in Woburn April 8, aged 75.

Standefer, Rufus Edd, Dunlap, Tenn.; Emory University School of Medicine, Emory University, Ga., 1915; died in the Sequatchie Memorial Hospital May 23, aged 72, of acute myocardial infarction, coronary occlusion, and generalized arteriosclerosis.

Staufft, Hannah Ophelia, Elkhart, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; died in Goshen Feb. 20, aged 87, of cerebral hemorrhage.

Steele, William Arthur ⊕ Havana, Ill.; Barnes Medical College, St. Louis, 1896; a member of the advisory board of welfare commission of Mason County; died April 13, aged 88, of bronchogenic carcinoma.

Steinberg, James ⊕ Los Angeles; Cornell University Medical College, New York City, 1911; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons; for many years associated with the Cedars of Lebanon Hospital; on the staff of the Mount Sinai Hospital and Clinic; died April 23, aged 66, of coronary thrombosis.

Steinharter, Stephan, Hempstead, N. Y.; Ludwig-Maximilians-Universität Medizinische Fakultät, Munchen, Bavaria, Germany, 1906; an associate member of the American Medical Association; in 1953 retired as clinical assistant in the medical division of Mount Sinai Hospital in New York City; died May 9, aged 75, of hypostatic pneumonia, hemiplegia, and arteriosclerosis.

Stelling, Richard Nunnally, Greensboro, N. C.; Medical College of Georgia, Augusta, 1930; member of the Medical Society of the State of North Carolina; veteran of World War II; died in the Moses H. Cone Memorial Hospital April 11, aged 53, of third degree burns.

Stephenson, Gordon Arnold ⊕ Summit, N. J.; University of Buffalo School of Medicine, 1929; certified by the National Board of Medical Examiners; fellow of the American College of Surgeons; for many years on the staff of the Overlook Hospital, where he died May 4, aged 53.

Stewart, James Golden, Sheridan, Wyo.; Northwestern University Medical School, Chicago, 1907; member of the Wyoming State Medical Society; died April 30, aged 74, of coronary thrombosis.

tewart, Omer Hall ⊕ Aurora, Ind.; Hospital College of Medicine, ouisville, Ky., 1907; served overseas during World War I; died in the Christ Hospital, Cincinnati, March 24, aged 74, of uremia following an operation for acute cholecystitis.

Stotts, Roscoe Glenn, Kenova, W. Va.; Starling Medical College, Columbus, 1906; an associate member of the American Medical Association; served as health officer; died May 22, aged 74.

Stringer, J. H., Memphis, Tenn.; Meharry Medical College, Nashville, Tenn., 1897; died May 4, aged 84.

Strout, Arthur Chester, Dexter, Maine; College of Physicians and Surgeons, Boston, 1904; member of the Maine Medical Association; served as vice-president of the Penobscot County Medical Society; on the staff of the Plummer Memorial Hospital; died April 14, aged 75.

Strunk, Aloysius C., Chicago; Jenner Medical College, Chicago, 1916; on the staff of the Woodlawn Hospital; retired member of medical staff, Swift & Company; died June 25, aged 70.

Sullivan, Gerald Augustine ⊕ Dwight, Ill.; Marquette University School of Medicine, Milwaukee, 1917; veteran of World War I; medical director of the Kelley Institute; died in the Veterans Administration Hospital May 6, aged 63, of carcinoma.

Sullivan, John Joseph, Jr. ⊕ Morristown, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; past-president of the Lackawanna County Medical Society; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; veteran of World War I; on the staff of the All Souls Hospital in Morristown; served on the staffs of St. Mary's, Scranton State, and Mercy hospitals in Scranton, Pa.; died in the Morristown Memorial Hospital April 12, aged 78, of ruptured aneurysm of the aorta.

Taylor, Mary Caroline, San Francisco; Cooper Medical College, San Francisco, 1905; an associate member of the American Medical Association; died Feb. 20, aged 89, of multiple fractured ribs and generalized arteriosclerosis.

Test, Frederick Cleveland ⊕ Glen Ellyn, Ill.; Georgetown University School of Medicine, Washington, D. C., 1895; associate professor of orthopedic surgery emeritus at Northwestern University Medical School, Chicago; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; veteran of World War I; served on the staff of the Cook County Hospital in Chicago; died in Wheaton July 8, aged 87.

Tincher, Edward Harper, Columbia, Mo., Homeopathic Medical College of Missouri, St. Louis, 1895; died in the Boone County General Hospital March 28, aged 87, of carcinoma of the pancreas.

Touhill, Neal Joseph ⊕ Dexter, Mo.; St. Louis University School of Medicine, 1929; died April 21, aged 52.

Tracht, Robert Russell ⊕ St. Paul; Loyola University School of Medicine, Chicago, 1932; specialist certified by the American Board of Ophthalmology; on the faculty of the University of Minnesota Medical School, Minneapolis, and the University of Minnesota Graduate School, Minneapolis-Rochester; member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society, and the Association for Research in Ophthalmology; on the staff of the Charles T. Miller Hospital; died May 25, aged 56, of heart disease.

Treat, David L. ⊕ Flint, Mich.; Starling Medical College, Columbus, 1898; fellow of the American College of Surgeons; at one time postmaster of Flint; served three terms as mayor, for many years president of the National Bank of Commerce; formerly chief surgeon of Buick Motor Division; in 1938 vice-president of the Michigan Association of Postmasters; died April 23, aged 82, of coronary thrombosis.

Umburn, Le Roy ⊕ Albion, Pa.; University of Pittsburgh School of Medicine, 1910; served overseas during World War I; vice-president of the First National Bank; school physician for 30 years; died in the Hamot Hospital, Erie, May 28, aged 71, of dissecting aneurysm of the aorta and arteriosclerosis.

Vande Roovaart, John Frank ⊕ Chicago; Northwestern University Medical School, Chicago, 1896; served on the staff of the Roseland Community Hospital; died June 21, aged 84.

Van Kirk, George Hiram ⊕ Kentland, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; veteran of World Wars I and II; died in St. Elizabeth Hospital, Lafayette, Feb. 14, aged 76, of acute coronary occlusion.

Van Meter, Julius Niel, Monrovia, Calif.; Drake University Medical Department, Des Moines, Iowa, 1913; an associate member of the American Medical Association; served as grade school trustee; died May 25, aged 69, of coronary thrombosis.

Vanni, Frank Lewis ⊕ Baltimore; New York Medical College, Flower and Fifth Avenue Hospitals, New York City, 1943; certified by the National Board of Medical Examiners; fellow of the International College of Surgeons; served during World War II; on the staffs of the Bon Secours, Maryland General, and St. Joseph's hospitals; died in the Johns Hopkins Hospital May 19, aged 39, of malignant hypertension.

Vasenius, Frederick Walter, Chisholm, Minn.; George Washington University School of Medicine, Washington, D. C., 1909, health officer; served as a medical missionary in Africa for the Seventh Day Adventist Church; died in the Chisholm Memorial Hospital April 23, aged 82.

Vornholt, Otto A. ⊕ Gallipolis, Ohio; the Hahnemann Medical College and Hospital, Chicago, 1919; fellow of the American College of Surgeons; on the staff of the Holzer Hospital, where he died June 13, aged 65, of lymphoma.

Walker, Louis Kyle ⊕ Ahoskie, N. C.; University of Maryland School of Medicine, Baltimore, 1911; chief of staff of Roanoke-Chowan Hospital, where he died May 17, aged 67, of pneumonia and cerebral hemorrhage.

Waller, Percy Gardiner ⊕ New Baltimore, N. Y.; Albany (N. Y.) Medical College, 1893; chosen the state's outstanding general practitioner for 1951 by the council of the Medical Society of the State of New York; served as president of the Greene County Medical Society; for many years health officer; member of the staff of the Memorial Hospital of Greene County in Catskill; died April 27, aged 85, of cerebral arteriosclerosis and chronic nephritis.

Ward, Gertrude Potter, Bloomfield, N. J.; Cornell University Medical College, New York City, 1900; an associate member of the American Medical Association; at one time health officer of Bloomfield and Glen Ridge; served as president of the Bloomfield Savings Bank; died May 20, aged 80, of cancer.

Warren, James Walter, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1904; member of the Louisiana State Medical Society; died in the Touro Infirmary April 15, aged 80.

Warren, William Ernest ⊕ Fort Payne, Ala.; Medical College of Alabama, Mobile, 1905; veteran of World War I; served on the staff of the Tennessee Coal, Iron and Railroad Company, Birmingham, and the Emergency Hospital in Ensley; died May 9, aged 77, of a brain injury received in an automobile accident.

Watson, Fred Cecil, Petersburg, Va.; Vanderbilt University School of Medicine, Nashville, Tenn., 1906; fellow of the American College of Surgeons; veteran of World Wars I and II; died April 19, aged 71.

Weedn, Alton James ⊕ Duncan, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1935; past-president of the Stephens County Medical Society; chief of staff, Weedn Hospital, where he died April 27, aged 48, of ventricular fibrillation and nephrosis.

Weir, Edward Claude ⊕ Council Bluffs, Iowa; State University of Iowa College of Medicine, Iowa City, 1900; member of the staff of the Jennie Edmundson Memorial Hospital; died May 29, aged 79, of coronary occlusion, arteriosclerosis, and congestive heart disease.

Weisel, William Francis, Quakertown, Pa.; Medico-Chirurgical College of Philadelphia, 1912; an associate member of the American Medical Association; past-president of the Bucks County Medical Society; for three terms local school director, serving as past-president and treasurer of the board; one of the founders of the Quakertown Community Hospital, where he was for many years medical chief of staff, and a past-president of the hospital board; died May 23, aged 73, of adenocarcinoma of the pancreas.

Weiss, Adolf Abraham ⊕ New York City; Columbia University College of Physicians and Surgeons, New York City, 1914; member cf the American College of Gastroenterology; on the staff of the Mount Sinai Hospital, where he died April 23, aged 65, of myocardial insufficiency.

Wells, John Bridger, Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1916; veteran of World War I; died May 3, aged 76.

Wenzel, Henry George, Westfield, N. J.; Long Island College Hospital, Brooklyn, N. Y., 1898; died in St. Petersburg, Fla., April 11, aged 91.

Westheimer, James Russell, Americus, Ga.; University of Toronto Faculty of Medicine, Toronto, Canada, 1927; died April 15, aged 60.

Whetstone, William Berry, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1903; an associate member of the American Medical Association; on the staff of the Presbyterian Hospital; died May 14, aged 77, of cancer.

White, George Martin ⊕ Rockmart, Ga.; Atlanta College of Physicians and Surgeons, 1906; served as president of the Polk County Medical Society; first chief of staff at Rockmart-Aragon Hospital; director of the Rockmart Bank; died in the Rockmart-Aragon Hospital April 11, aged 76, of aspirational pneumonia and cerebral thrombosis.

Wiborn, J. Auburn, Santa Barbara, Calif.; Dartmouth Medical School, Hanover, N. H., 1897; at one time on the staff of the French Hospital in San Francisco; died in the Santa Barbara Cottage Hospital April 17, aged 84, of arteriosclerotic and hypertensive heart disease.

Wildman, Otis ⊕ Captain, U.S.N., retired, Washington, D. C.; Indiana University School of Medicine, Indianapolis, 1917; specialist certified by the American Board of Pathology; fellow of the American College of Physicians; entered the U. S. Navy Sept. 7, 1917; retired Nov. 1, 1943; veteran of World Wars I and II; died in the U. S. Naval Hospital, Bethesda, Md., May 14, aged 65, of myocardial infarction.

Williams, John Charles, New York City; University of Vermont College of Medicine, Burlington, 1912; for many years on the staff of St. Luke's Hospital; died April 25, aged 67.

Williams, John Hugh, Muncie, Ind.; Starling Medical College, Columbus, 1907; member of the Indiana State Medical Association; served as county coroner and city health officer; died May 12, aged 76, of carcinoma of the rectum.

Wilson, Doxey Robert ⊕ San Jose, Calif.; Cooper Medical College, San Francisco, 1908; fellow of the American College of Surgeons; formerly superintendent of the Santa Clara County Hospital; veteran of World War I; died in the O'Connor Hospital May 1, aged 72, of injuries incurred in a fall.

Wilson, George Kissick ⊕ Streator, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1907; on the honorary staff of St. Mary's Hospital, where he died May 3, aged 76, of cerebral hemorrhage.

Wise, Louis John, Cleveland; Starling Medical College, Columbus, 1901; died May 31, aged 77.

Wood, Granville Numan ⊕ Palo Alto, Calif.; Stanford University School of Medicine, San Francisco, 1924; also a lawyer; for many years city councilman; died in the Palo Alto Hospital May 2, aged 67, of heart disease.

Wood, William Charles, Pleasantville, N. J.; Jefferson Medical College of Philadelphia, 1908; specialist certified by the American Board of Otolaryngology; member of the Medical Society of the State of Pennsylvania; served on the faculty of the University of Pennsylvania Graduate School of Medicine, Philadelphia; formerly on the staffs of the Children's Hospital, Mary J. Drexel Home, and the Lankenau Hospital, Philadelphia; died in the Graduate Hospital of the University of Pennsylvania, Philadelphia, June 4, aged 70, of ruptured aortic aneurysm.

Worten, Divonis ⊕ Pawhuska, Okla.; University of Nashville (Tenn.) Medical Department, 1902; donor of the Worten Athletic Field at the Oklahoma Baptist University at Shawnee; died May 24, aged 85.

Wright, Edward Mack, Warsaw, Ohio; Eclectic Medical Institute, Cincinnati, 1896; past-president of the Coshocton County Medical Society; served as county coroner, on the city board of health of Coshocton, and on the board of education of Coshocton and Warsaw; died in the Rochester (Minn.) Methodist Hospital April 25, aged 83, of bronchopneumonia.

Wright, Walter Nelson ⊕ Rose Hill, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; for many years mayor; served as president of the school board; died in Oskaloosa May 8, aged 89.

Youngblood, Fred ⊕ Huntsville, Ark.; Beaumont Hospital Medical College, St. Louis, 1897; died Feb. 24, aged 79, of coronary thrombosis.

Zacks, Morris Joseph ⊕ Conneautville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1933; past-president of the Crawford County Medical Society; served on the Conneaut Valley school board; on the staff of the Meadville (Pa.) City Hospital; died in Everett April 5, aged 49, of coronary occlusion.

CORRECTION

Herman, Harold.—In THE JOURNAL (Aug. 4, 1956, page 1405) an obituary of Dr. Harold Herman, who is currently in practice at 229 E. 79th St., New York City, was erroneously published. Dr. Harold C. Herrman of 639 W. 173rd St., New York City, died April 13, 1956.

AUSTRIA

Endocranial Complications in Otorhinolaryngology.—At the meeting of the Society of Physicians of Vienna on June 22, Dr. E. Bauer reported a series of seven patients with endocranial complications, including three with meningitis, three with sinus thrombosis, and one with extradural abscess, all of which conditions developed without their characteristic symptoms. The fact that the endocranial complications of the inflammatory diseases in the field of otorhinolaryngology are becoming increasingly less typical is attributed to modern chemotherapy. In addition to the local symptoms caused by the primary disorder (otitis and sinusitis, acute and chronic), the various complications exhibit only such vague symptoms as headache, fatigue, lack of drive, and exhaustion, often simulating influenza. Because of this lack of characteristic symptoms, the disease may persist and progress in a latent form. This favors the development of complications. Examination of the spinal fluid is particularly important in these patients, because this simple test can be carried out at any time and permits the recognition of an incipient endocranial complication. Otologists should not dispense with modern chemotherapy but should use it only for exact indications and with attention to time of onset and dosage. They should also remember that, despite the use of sulfonamides and antibiotics, endocranial complications that require surgical treatment may develop.

Oxygen Therapy in Failure of the Peripheral Circulation.—At the same meeting Dr. W. Möller of Kassel, Germany, said that oxygen therapy has advanced beyond the experimental stage and has become an integral part of the conservative treatment of failure of the peripheral circulation in many clinics. A comparison of the sphygmograms of the pulse in the extremities after the insufflation of oxygen reveals that the painful reactions caused by the embolic occlusion and blockage of the vessels, as evidenced in formation of gangrene, are effectively counteracted by the oxygen therapy. Oxygen-foam therapy represents a further advance in oxygen therapy. In order to adjust the size of the foam vesicle to the smallest blood vessels, the oxygen is incorporated into fluids compatible with blood. These vesicles pass through even the minutest capillaries so that they do not involve the danger of embolization. It is impossible to effect complete recovery by means of oxygen therapy, but the function can be restored and the patient freed from symptoms. Clinical and arteriographic findings show that a collateral circulation capable of meeting the functional demands requires from three to six months for its complete development. The treatment proved successful in 70% of the outpatients and in 80% of the hospital patients. The best therapeutic results can be expected when treatment is begun during the early or "silent" phase, or during the atypical ischemic stage. No treatment can be regarded as effective in all patients. The insufflation of oxygen must be complemented by oxygen therapy in the form of cer-aerosols (Lanthasol), cellular therapy (particularly by placental therapy), short-wave diathermy, breathing exercises, and diet. These various methods must in turn be complemented by giving oxygen.

BELGIUM

Infectious Embryopathies.—At the Society of Gynecology and Obstetrics, François and Verriest said that rubella or embryopathy is chiefly characterized by congenital malformations, localized (1) in the eye (central or total cataract, microphthalmia, and dystrophy of the retina); (2) in the inner ear (complete or partial deafness and disturbances in the labyrinth); and (3) in the heart (patent ductus arteriosus and interauricular septal defect). Other deformities are rare. The earlier the maternal infection, the more likely is the lens to be affected. If the mother has rubella in the first trimester of her pregnancy, the fetus may be aborted, stillborn, or born with an embryopathy. The percentage of children affected varies from 10 to 50 according to the virulence of the infecting agent. Deformities are probably due to the direct action of the virus or its toxins on the developing organs. Treatment must be preventive and consists of immunization of the mother with convalescent serum during the incubation period of the disease. Mumps, chicken pox, poliomyelitis, and infectious hepatitis cause embryopathy but rarely.

Children of Tuberculous Parents.—Graffar and Asiel in *Acta tuberculosea belgica* reported on the children of tuberculous parents in Brussels who had been divided into those who had and those who had not been vaccinated with BCG. In an attempt to protect the latter group, the tuberculous parent is hospitalized or the child is isolated in a preventorium. The reluctance of many parents to be separated from their children for a long time has interfered with this attempt and has led to a high incidence of tuberculosis among these children. The incidence of tuberculosis was four to seven times greater in the unvaccinated group.

Androgenic Smears.—Pundel of Luxembourg reported to the Society of Gynecology and Obstetrics that testosterone given in sufficient doses to a castrated woman or one in the menopause causes hyperplasia of the external basal and intermediate layers of the vaginal epithelium and the smears show basal external and intermediate cells characterized by nuclear and cytoplasmic hypochromatism. The same findings that the author designates as pure androgenic reactions may appear spontaneously in a woman at the menopause and in young women in a certain state of adrenocortical hyperactivity, but, in addition to these purely androgenic smears, there are others that show mixed estrogen-androgenic, progesterone-androgenic, and other even more complicated findings.

Herniation of the Nucleus Pulposus.—At the University of Louvain, Van der Bergh studied a series of 80 patients who had undergone surgical treatment for herniation of the nucleus pulposus. In 50 the sciatic pain was relieved, and in the rest there was complete cure; 48 patients were able to return to work. Hernias between the fifth lumbar and first sacral vertebrae were the easiest to heal. The best results are obtained with large hernias. Only 50% of persons doing physical work recovered completely as compared with 80% for those doing mental work.

Lead Poisoning.—At a meeting of the Society of Radiology, Chairdon stated that, at the time of the periodic hematological examinations of the members of the x-ray service of the Military Hospital of Brussels, serious lead poisoning was observed in more than half the personnel. This manifested itself by an increase in basophilic granulations in the erythrocytes. Similar poisoning was observed at another military hospital. It is principally due to the handling by the workers of cassettes contaminated by lead dust, which comes from the passage of the cassettes through the lead-lined cassette holders and from the handling of lead-identifying figures and cases. Among the preventive measures suggested was painting the lead figures, plates, and other lead accessories used in x-ray services with a durable varnish.

Medical Inspection in Schools.—Medical inspection of school children is required by law, but its application is inadequate, especially at the high school levels. It also neglects the hygienic supervision of the teaching staff and other school employes. Professor Goossens proposed to the Belgian Association of Hygiene and Social Medicine amendments in the present legislation and advocated the creation of a central bureau to advise the local services and coordinate the school medical inspection services. The school medical inspection should be supervised by a physician trained in school hygiene, physical education, otolaryngology, ophthalmology, orthopedics, psychiatry, and the reading of roentgenograms of the chest.

The items in these letters are contributed by regular correspondents in the various foreign countries.

BRAZIL

Blood Groups.—Although the blood groups do not in themselves constitute a sure means of anthropological classification, they may be used as a valuable aid to such a classification. A study of the O, A, B, and AB blood groups in 482 adults and a study of the M and N groups in 100 adults in Goa (Portuguese India) was carried out by Dr. A. X. da Silva. A great predominance of the O group in both Christians and Hindus was observed. The serologic difference between Hindus and Moors was striking. In the Moors a predominance of the A group was noted. This predominance has also been noted in Europeans, but, while the order of predominance is A, B, and O in the Moors, it is A, O, and B in the Europeans. The higher incidence of the B group in the Moors as compared with the Europeans is perhaps due to the Dravidian influence in the peoples of southern India with whom they had been crossed. There is a great predominance of the M factor over the N factor in the population of Goa. A high incidence of the M factor is observed in those belonging to the O group. The N factor was not found in those of the A group.

CANADA

Carbutamide.—In a symposium on carbutamide in the June 15 issue of the *Canadian Medical Association Journal*, Sirek and Sirek report that this drug lowered the blood sugar level in 67% of a series of depancreatized and depancreatized and hypophysectomized (Houssay) dogs. It appeared to potentiate insulin, 1 unit every 8 to 10 days being sufficient to control the blood sugar level in a dog previously requiring 24 units daily. The presence of insulin appeared to be necessary for the action of carbutamide, since when no insulin was given the blood sugar level tended to rise. Campbell noted that the effect of carbutomide on the depancreatized dog given insulin was greater than on the dog with diabetes induced by hypophysectomy. The drug lowered sugar excretion, the fasting blood sugar level, and the insulin requirement. Its influence on metabolism was limited. On withdrawal of insulin, it did not prevent glycosuria in the hypophysectomized diabetic or severe upsets in the depancreatized animal.

Clarke and co-workers performed in vitro studies. Carbutamide inhibited glucose production by liver slices incubated in a phosphate-saline medium. Hence carbutamide may exert a hypoglycemic action by reducing the glucose output of the liver. Adding insulin or glucagon nullified the effect of the drug. The drug also increased the oxygen consumption of liver slices in a pyruvic acid substrate, inhibited cytochrome oxidase, and reduced glucose uptake by isolated rat diaphragm. Wrenshall and Best attempted to answer the question whether the effectiveness of orally given sulfonylureas in restoring blood and urinary sugar levels to normal in diabetics depends on the presence of a supply of endogenous insulin. They showed that there are basic similarities in pattern between the presence or absence of appreciable amounts of extractable insulin at autopsy and the effectiveness or ineffectiveness of carbutamide in restoring the blood sugar level to normal in human diabetics. This accounts for the effectiveness of the drug in adults whose diabetes is of short duration. Whether the extractable insulin is a measure of the ability of the pancreas to produce insulin or not remains to be seen.

Hawkins and co-workers showed that carbutamide in rats depressed the glucose-6-phosphatase activity of the liver. Freidlich and co-workers injected the drug intravenously into rats three hours before giving glucose by mouth and found that it reduced the rate of glucose absorption from the intestine, as shown by the greater residue of reducing substances in the gastrointestinal tract of rats treated with carbutamide. Ashworth and Haist showed that administration of carbutamide to rats for three to five weeks leads to a significant increase in islet tissue, suggesting that the islets are stimulated by the drug.

Ogryzlo and Harrison described the effect of carbutamide on a patient who had undergone pancreatectomy several years previously. The drug lowered the blood sugar level to some extent but could not replace insulin and was erratic in its effect. It is admitted that some pancreatic tissue might have persisted. Leibel studied five patients whose diabetes came on after they reached maturity but who did not require insulin. Only three of them gave a good response to carbutamide. The effect of the drug tended to appear after a delay of up to two weeks, a fact already noted in Germany. Watt reported the failure of carbutamide to control labile diabetes in two patients. Charles noted that of four elderly diabetics only one achieved fairly good control with carbutamide therapy alone. Metzler had two patients (one elderly and one middle-aged) with mild diabetes who were satisfied with carbutamide; in the third patient, a younger person, treatment was a failure. Chase noted a good hypoglycemic effect in only one of her two patients; a troublesome rash developed in the other. Hall and co-workers obtained adequate control in three of five adults, but saw no results in a thin diabetic receiving 2 gm. of carbutamide by mouth daily. Spaulding produced hypoglycemia in nondiabetic subjects within three or four days and also noted a response in three persons with mild diabetes. Chute and Bain recorded the appearance of blotchy erythema and pruritus without hypoglycemia in three recently discovered juvenile diabetics; in two other cases of longer standing, only one patient achieved a slight hypoglycemic effect.

Smith and Kumar tried to devise a test for response to carbutamide by constructing insulin-tolerance curves before and after administration of the drug. Among the first 15 patients studied, they found 4 types: those with (1) a fall in the curve; (2) little change in the curve but a fall in the fasting blood sugar level; (3) a combination of 1 and 2; and (4) no change. Type 2 would benefit from carbutamide but not type 1, since type 2 must have an endogenous supply of insulin. The response in type 3 was unpredictable. The general opinion after these studies is that about 10% of all diabetics will benefit from carbutamide. It is useless for children and patients with acidosis and is most likely to help the obese pyknic adult with a mild diabetes of short duration. The full impact of the drug takes several days to develop and may continue for several days after its withdrawal. Some experiments with animals suggest that caution is necessary in patients already taking sedatives (the sleeping time after administration of a barbiturate was potentiated by carbutamide), tranquilizers, and possibly even alcohol.

C. M. A. Annual Meeting.—For its 89th annual meeting in June, the Canadian Medical Association went back to Quebec, where it was founded in 1867 and which it had not visited for 30 years. In addition to guests from the United States such as Dr. P. R. McDonald of Philadelphia and Dr. Lawrence Fallis of Detroit, there were speakers from the United Kingdom: Sir Howard Florey, who talked about micrococcic (staphylococcic) infection, and Professor McCance, the Cambridge nutritionist, who discussed unconsidered mechanisms in the maintenance of stability of the internal environment. The outgoing president, Dr. Clarence Routley, installed his successor, Dr. Renaud Lemieux, head of the department of medicine at Laval University, Quebec, in the presidency. Dr. Lemieux, who has been a member of the executive committee for some time, is the first French-Canadian to become president for several years.

Traffic Accidents.—The growing toll of automobile accidents has led to the sponsorship by the Canadian Medical Association of a Canadian Medical Traffic Accident Research Foundation with the aid of the Association des Médicins de Langue Française du Canada, the Royal College of Physicians and Surgeons of Canada, and the Canadian Bar Association. The purpose of the proposed foundation, for which there is a likelihood of substantial funds from industry, is collection of data and their analysis to assist in lowering morbidity and mortality due to traffic accidents. It is believed that the epidemiological approach may fruitfully be applied to these problems. To stimulate further interest by physicians in the problems of traffic accidents, a symposium was held at the annual meeting. The statistics for Canada show that accidents cause about 3,000 deaths in Canada annually and the loss of 50 million dollars through direct property damage. The number of accidents and the number of deaths are steadily increasing, and the automobile is now the chief cause of death in the 5-23 year age group. Of concern to physicians are medical and physical standards for drivers, research into psychiatric factors involved in accidents, development of a simple test for alcoholic intoxication, the organization of good first-aid treatment, efficient transportation for casualties, and adequate hospital care for the injured. Collection of statistics and analysis of data are necessary, if only as a basis for making proposals to nonmedical organizations, including the automobile industry. The role of alcohol was variously assessed by speakers; one thought that in his province it had a direct relation to 90% of accidents, while another held that in his area it was concerned only in 4%. This is an area in which more objective figures are needed.

College of General Practice.—The College of General Practice of Canada held its second annual meeting in Quebec in conjunction with the meeting of the Canadian Medical Association. This was purely a business meeting, but the college plans to inaugurate a scientific meeting next winter. The college committee that has been studying intern training for general practice has turned in a detailed report, in which a second year of intern training, specifically called a residency in general practice, is recommended. The college believes that this second year should be different from that leading to specialization and should include three months of general medicine, including dermatology, three months of obstetrics and gynecology, three months of general emergency surgery, one month of anesthesiology, and two months of pediatrics. After completion of this program, the college recommends two to four weeks of preceptorship with a senior practicing physician.

FRANCE

Complications After Smallpox Vaccination.—In the *Semaine des hôpitaux de Paris* (June 6, 1956, page 1962) Lamache and co-workers presented a series of 30 complications following smallpox vaccinations, which they divide into four groups: (1) local accidents, (2) allergic manifestations (chiefly asthma and eczema), (3) a sudden senescence with a rapid decline of physical and intellectual activity, and (4) aggravation of disease (cancer of the breast, tuberculosis, cirrhosis of the liver, nephritis, rheumatism, and organic and functional neurological disorders). In a 70-year-old woman cerebral arteriosclerosis and hemiplegia of the left side caused by encephalomalacia followed vaccination. A hyperacute nephritis developed, and she died. The authors concluded that, in patients with epitheliomas, acute hemopathies, tuberculosis, or severe cerebral arteriosclerosis, smallpox vaccination is absolutely contraindicated. The average interval between the vaccination and the complication was 15 days.

Psoriasis.—At the May 11 meeting of the Medical Society of Paris Hospitals, Billiottet reported a series of 10 patients with psoriasis treated with nicotinic acid derivatives. Good results were observed in five, and, although the duration of the disease did not appear to affect the results, the best results were obtained in those who had the most florid eruption.

INDIA

Leukoderma.—Fernandes and Mehta in the *Journal of the Indian Medical Profession* for June state that, although at one time leukoderma was of interest only to the dermatologist, today it is being studied by the internist, endocrinologist, radiologist, and surgeon. After any intestinal disorder is excluded, the disease is treated locally with natural or artificial ultraviolet light. Treatment with methoxsalen and gold has also been tried. Some patients however, especially those whose condition is chronic, fail to respond to any of the treatments mentioned, and these may be treated surgically. Formerly the patches were first abraded with a special sandpaper and then treated with a solution of gold chloride and tannic acid. The results were not satisfactory, as the degree of pigmentation could not be controlled. Later, therefore, intradermal pigmentation after the method of Conway was performed under anesthesia. The pigments used must be insoluble and free from harmful local or systemic effects. The border of hyperpigmentation that is almost always present surrounding an area of leukoderma is removed with electric drills. Surgical treatment alone cannot prevent the development of new patches, and, in the spreading type of the disease, the cause should be found and removed if possible.

In the *Bulletin of the Calcutta School of Tropical Medicine* for April, 1956, Chakrabarti and Banerjee reported the results of treatment in 75 patients who had leukoderma with a methoxsalen paint. The lesions varied from a few small patches to numerous and extensive areas, and the duration of the disease ranged from a few weeks to several years. The period of treatment varied from three months to two years. The treatment consisted of local application of the paint combined with ultraviolet ray therapy. The oral administration of methoxsalen was found to be of little value. Only 2 patients with small patches of recent origin were completely cured, while 34 showed no improvement and 39 were improved in varying degrees. Response was better in cases of recent origin. Lesions on the trunk and face responded better than those on the extremities Lesions on mucous membranes, palms, and soles showed hardly any change. Some of the side-effects observed were local erythema, dermatitis, change in consistency of the skin, which became hard and scaly, and hyperpigmentation. Sometimes hyperpigmentated patches with fine exfoliation developed in regions distant from the site of application of the paint. The treatment was thus found to be of help in only a small percentage of patients, and it was affected by the size, duration, and location of the pigmented patches.

Activity of the Adrenal Cortex.—Chakrabarti and Banerjee (*Indian Journal of Medical Research*, April, 1956) studied the adrenocortical activity in patients suffering from various common infectious diseases with a view to the rational therapeutic use of corticotropin. There is a profound fall in the circulating eosinophils after the injection of corticotropin, epinephrine, and 11-oxysteroids. This led to the development of a four-hour eosinopenic response test to parenterally given epinephrine as a means of evaluating the functional integrity of pituitary-adrenal axis. A 50% fall in the circulating eosinophils indicates normal adrenocortical function. In the present investigation, the eosinopenic response, four hours after the injection of 0.3 cc. of a 1:1,000 solution of epinephrine, was studied, and levels of serum sodium and potassium and blood ascorbic acid were estimated in patients suffering from pneumonia, meningococcic meningitis, tuberculous meningitis, typhoid, and tetanus during the active phase of the disease, to study the adrenocortical activity, and compared with values obtained in healthy adult subjects. The series contained 28 normal subjects, 25 patients with meningitis, 25 with tetanus, 17 with tuberculous meningitis, 23 with typhoid, and 22 with pneumonia. The mean fall in the circulating eosinophils was 59.8% in normal subjects, while the average response in the diseases mentioned varied between 25.6 and 35.4%. There was a significant decrease in the serum sodium value and blood ascorbic acid level and an increase in the serum potassium contents in all the patients. All these readings indicated hypoactivity of the adrenal cortex in the disease studied.

Congestive Heart Failure.—The good effects of Karrel's diet in the treatment of peripheral edema in congestive heart failure are due to its low caloric value and low sodium content. While studying the electrolyte composition of coconut water, Shah and co-workers (*Indian Journal of Medical Research*, April, 1956) found that it was low in sodium and high in potassium content, especially when compared to milk. They used it to treat a series of patients with congestive heart failure who had peripheral edema. Group 1 was given coconut water, and group 2 received Karrel's diet. The patients were weighed on admission. During the study, each patient's weight, total fluid intake, and urine output were charted. Examination of blood urea, nonprotein nitrogen, and urine was carried out, and electrocardiograms were made. Daily estimations of sodium and potassium content of the coconut water were made with a flame photometer. One 0.25-mg. tablet of digoxin was given three times a day to patients in both groups. It was noticed that coconut water administered in sufficient quantity is a potential diuretic. All the patients in group 1 had a marked diuresis with significant increase in the excretion of sodium and a marked loss of weight, as compared to group 2. Three of the patients on Karrel's regimen required mercurial diuretics after five days, while none of the patients in group 1 required any supplementary therapy. The clinical improvement was also striking.

The diuretic effect may be due to the low sodium and high potassium content of the coconut water. No toxic reactions were observed, but in patients with renal damage it should be used with caution.

Serum Cholinesterase.—In a report in the *Bulletin of the Calcutta School of Tropical Medicine* for April, Dutta and co-workers state that the main site of synthesis of cholinesterase is the liver. An estimation of this nonspecific enzyme in the serum may therefore be of value in assessing the degree of liver derangement associated with different lesions. The authors compared the cholinesterase content of the serum of 175 unselected hospitalized patients and 20 normal controls by measuring changes in pH. This usually ranged between 0.50 and 0.90. Low values of 0.22 to 0.40 were obtained in many patients with cirrhosis of the liver, nutritional edema, ascites, and severe anemia. Values within the normal range were obtained in patients with diabetes mellitus, hyperthyroidism, rheumatic fever, bronchial asthma, allergy, tropical eosinophilia, hypochlorhydria, duodenal ulcer, tonsillitis, giardiasis, appendicitis, and obesity. Simultaneous measurements of the cholinesterase and serum albumin were made on 30 random samples. No constant relation was found between the two, although a normal cholinesterase activity was generally found only in association with a normal serum albumin level. Low albumin levels were associated with low enzyme activity. Serial estimations rather than the single determination of cholinesterase and serum albumin may be of value in assessing liver function during the progress of a disease.

NORWAY

Campaign Against Obesity.—The Norwegian National Association for Diet and Health took a practical step in the campaign against overweight by issuing Prof. Haakon Natvig's new height-weight tables, which enable the reader to see at a glance whether he or she weighs too much. Natvig and co-workers in *Tidsskrift for den norske lægeforening* (June 1, 1956) point out that a strictly scientific basis by which to define the ideal or normal height-weight relationship is still lacking. Their own material has included both the fat and the lean, and more cannot be claimed for it than that it is based on a collection of about 15,000 healthy persons fit for work. Judged by this somewhat arbitrary standard, every third Norwegian between the ages of 30 and 49 years is overweight.

SWEDEN

Driving Licenses for Diabetics.—The liability of diabetics to develop diseases of the retina and lens has been considered so serious that up to 1950 the diagnosis of diabetes was enough in itself to disqualify an applicant for a driving license in Sweden. As the hardships thus inflicted seemed unnecessary in some cases, protests were made in parliament, and steps were taken to differentiate between diabetics with and without disqualifying retinal damage. In 1952 the public health service instituted a follow-up examination of 25 diabetics whose applications for driving licenses had been rejected earlier because they were suffering from diabetic retinopathy. Eight were considered fit to drive, 10 others were borderline cases, and 7 were clearly disqualified. Since 1952 the regulations governing the issue of driving licenses to diabetics have been modified with a view to a fairer discrimination in individual cases. At the same time the precaution has been taken to limit the duration of such a license to one year, after which reexamination is required. In 1955 Dr. Tore Kornerup found evidence of diabetic retinopathy in 47% of 1,000 unselected diabetics. His latest publication, in *Nordisk medicin* for May 24, 1956, deals with 1,137 diabetics over the age of 15 years who were examined with special reference to their fitness to drive a car. In 48% there was no sign of diabetic retinopathy, and in 34% the diabetics were fit to drive in spite of their retinopathy. Kornerup draws attention to the fear of sudden deterioration of vision on account of hemorrhages into the eyes of diabetics. This fear should be corrected by the fact that his material does not include a single patient in whom vision had suddenly been impaired by a hemorrhage or by an exudative retinopathy. To be sure, a sudden hemorrhage into the vitreous body may occur in a patient with advanced proliferative retinopathy, but for such patients driving is already out of the question.

Pulmonary Tuberculosis Relapses.—It has lately been argued that the frequency of relapse in patients with pulmonary tuberculosis has risen with the introduction of modern remedies. Hillerdal and Spangberg reported their observations on this matter in *Svenska läkartidningen* for May 11. They chose the year 1944 as representative of the preantibiotic era and the three years 1949-1951 as representative of the antibiotic era. In 1944 the death rate for sanatorium patients was 15%, and in the period 1949-1951 it was 5%. In 1944 the relapse rate for 104 sanatorium patients was 39%, whereas in the period 1949-1951 for 255 such patients it was 36%. These findings were based on a follow-up examination brought up-to-date in the autumn of 1955. A scrutiny of the 255 case reports showed that, whereas the relapse rate for the total was 36%, it was only 25% for those patients in whom chemotherapeutic measures had been combined with operative treatment. On the other hand, the relapse rate was 41% for those receiving chemotherapeutic treatment without operation. It would thus seem that the relapse rate in patients with pulmonary tuberculosis has fallen rather than risen in response to modern treatment.

Asbestosis.—The first case of asbestosis in Sweden was diagnosed in 1953. The patient was a 63-year-old man who had been employed in the asbestos industry for 17 years. When he first came under medical supervision he was suffering from dyspnea, cyanosis, and other manifestations of advanced asbestosis. This case led to a search for asbestosis among 60 workmen between the ages of 43 and 63 years who had been employed in the asbestos industry for periods ranging from 5 to 17 years. In eight of these, some degree of asbestosis was discovered. These men did not, however, present symptoms that could be traced to this condition. The discovery of these cases has now led to the inclusion of asbestosis among the reportable diseases and the adoption of measures calculated to prevent it in the future. The growing importance of asbestos as a possible source of industrial disease was emphasized by Ahlborg and Hansson in *Svenska läkartidningen* for May 25.

SWITZERLAND

Medical Education.—Many foreign students get their medical education in Switzerland, where a complete medical course is offered in Zurich, Bern, Basel, Geneva, and Lausanne. The course consist of 13 semesters, of which the first 5 are devoted to basic sciences. There are no clinical clerkships such as are found in France, but the student is initiated in the examination of the patient during a semester of preliminary clinical work. After 13 semesters of medical education the student must take a federal examination. Once in possession of his diploma, valid in all the Swiss cantons, the young phisician must take at least one year of internship. The interns work full time and are paid by the state. After four of five years a physician may qualify as a specialist and receive the title of F. M. H. (Federatio Medicorum Helveticorum). As a rule, every physician, even the most modest practitioner living in a suburb or the country, will not begin to practice before having served two or three years as an assistant physician in a large hospital. After that, at the age of about 30 years, he settles when and where he wishes. The university hospital clinic is a therapeutic and diagnostic center for medically indigent outpatients, a few of whom may be admitted to the infirmary (polyclinic). At the polyclinic each neophyte is responsible for one of the city's quarters, and he follows each patient's course after discharge from inpatient status.

Few physicians in Switzerland devote full time to scientific research, as the time of the assistant physicians is completely filled with caring for the sick. Recently, however, the larger chemical manufacturers have undertaken the total support of an assistant physician and provided him with a laboratory and technicians; the Swiss Academy of Medical sciences has granted research scholarships and subsidies; and the National Fund for Scientific Research has been created.

Clinical tradition and the struggle against excessive specialization characterize the spirit of the medical schools. For a population of more than 4 million, Switzerland depends on 4,500 practicing physicians (about one for every 1,000 people) and more than 2,500 assistant physicians in the hospitals. Furthermore, Switzerland has been able to maintain a free medical profession at a time when many other countries are organizing national health services in response to social necessities that Switzerland does not know.

Swiss Tuberculosis Association.—At a meeting of the Swiss Tuberculosis Association at Neuchâtel in April, Dr. M. Chauvet of Geneva said that, although the diagnosis of pulmonary diseases is being continually improved, there remain a certain number of puzzling cases in which biopsy of the prescalene ganglions or anatomic reflection of the hilar ganglions may provide valuable information. The operation is easy, can be done on an ambulatory basis, and presents no risk. Positive results are often obtained in patients with cancer, tuberculosis, Boeck's sarcoid, lymphogranuloma, and lymphosarcoma. Dr. Van Epereum of Davos, discussing chronic bronchitis accompanying tuberculosis, stated that the diagnosis depends on the search for eosinophils in the sputum and on the simultaneous establishment of a reduction of the pulmonary function in relation with the diminution of the caliber of the bronchioles. This diagnosis is important, as much because of the functional consequences of this disease as for the fact that the therapy of subjacent pulmonary tuberculosis is frequently efficacious only after this nonspecific factor has been eliminated.

Dr. Duggeli of Davos-Wolfgang reported his results with pyrazinamide. This product shows lasting activity only in combination with isoniazid. Duggeli used it on 65 patients with chronic cavitary disease after failure with other methods of treatment, giving 30 to 40 mg. of pyrazinamide and 4 to 6 mg. of isoniazid per kilogram of body weight. The effect, although irregular, appears to depend principally on the sensitivity of the bacilli to isoniazid. When there is resistance to 5 mcg. of isoniazid per cubic centimeter of stock solution, clinical and radiological improvement is observed in 75% of the patients, when there is resistance to 10 mcg., improvement is observed in only 50%. If there is a partial resistance, a halt in progress or an exacerbation occurs after about eight weeks, and, if there is total resistance, there is no radiological improvement. The secondary effects consist essentially in a hepatotoxic attack ithout aggravating the pulmonary tuberculosis, in contrast to e behavior of patients with epidemic hepatitis. Because of its xicity pyrazinamide should be reserved for special cases. Dr. Nick of Arosa used pyrazinamide alone on nine patients who were resistant to all other medicaments. In all nine, drug resistance appeared after four to eight weeks with either a sudden or a progressive exacerbation of the disease. In three patients a combination of pyrazinamide and aminosalicylic acid gave good results.

Dr. Marki of Arosa said that cycloserine is eliminated in high concentration in urine, which explains its value in urogenital tuberculosis. Such secondary effects as anorexia, constipation, neurological disorders with epileptiform fits, fever, and sometimes purpura have been observed. Bacterical resistance develops rapidly. Cycloserine must be given with another antibiotic. Marki gave 12 patients 1 gm. of cycloserine three times a week alternated with 1 gm. of streptomycin twice a week. Even under these conditions, resistance may develop quickly. The method of action of cycloserine is unknown, since it is not very active in vitro. Professor Daddi used the drug on three patients and observed no resistance. He believes that it is advantageous to give it on three or four consecutive days followed by two or three days of rest. Dr. Favez of Lausanne said the indications for use of cortisone in the treatment of pulmonary tuberculosis depend principally on its anti-inflammatory action and include tuberculous pneumonia, recent miliary infections, and serous effusions. Cortisone, by diminishing the capillary permeability and the permeability of the ground substance, produces a functional isolation of the tuberculous focus. In old lesions this action is undesirable since it prevents antibiotics from reaching affected zones. On the other hand, in exudative lesions, where the specific focus is not important in regard to perilesional reaction, cortisone is of some benefit, for the patient is sick more from this excessive reaction than from his tuberculosis. Cortisone must always be applied under cover of antibiotics. At the beginning of such treatment, there is the risk of massive liberation of bacilli.

Drs. Tredelenburg and Vischer of Davos-Wolfgang reported that isoniazid-resistant bacilli are characterized by a slow growth, a reduced catalasic activity, and a reduction of the index of virulence for the guinea pig. The clinical course of infection with these organisms is usually favorable because they rarely produce thickening of the cavitary walls or distant disseminations.

UNITED KINGDOM

Toxicity of Carbimazole.—Fraser and his co-workers have surveyed the effect of carbimazole, with special reference to its toxicity, on 1,046 patients receiving it for thyrotoxicosis (*Brit. M. J.* 1:1453, 1956). It blocks the production of thyroid by interfering with the organic binding of iodide into tyrosine, probably by preventing the oxidation of iodide to iodine. The survey was carried on over a mean period of 9.2 months, and during this period 0.5% of the patients showed major and 1.5% showed minor toxic reactions. The minor reactions included rashes, nausea, headache, jaundice, gastric distress, and allergic phenomena (swelling, urticaria, and polyarthritis); major reactions were depression of blood-forming tissues and the drug-fever syndrome. Granulocytopenia occurred in only one patient. Most of the reactions were of the allergic type and occurred in patients with a history of allergy. The authors point out that carbimazole is the least toxic of the antithyroid drugs. It was responsible, however, for the death of one patient from aplastic anemia.

Serum Proteins in Pulmonary Tuberculosis.—Gilliland and his co-workers examined the serum proteins of 327 tuberculous patients by means of paper electrophoresis and correlated the pattern obtained with the clinical condition of the patients, using 28 contacts living in the same environment as controls (*Brit. M. J.*, 1:1460, 1956). The patient's condition was recorded clinically, radiologically, and bacteriologically. In the tuberculous patients, there was a progressive fall in albumin concentration and a progressive rise in the gamma$_2$-globulin concentration as the extent of the lesion increased. These fractions were restored toward normal levels as the disease became arrested. There was no difference between the albumin–gamma$_2$-globulin ratio in patients with recent cases of tuberculosis and those with long-standing cases. The ratio became progressively lower, however, with increasing evidence of activity. After successful treatment with antituberculous drugs, the albumin–gamma$_2$-globulin ratio returned to normal. Whereas only 7 of the 327 patients had normal serum protein levels, nearly 50% had a normal sedimentation rate, showing how insensitive the latter is as an indicator of tuberculous activity. The authors concluded that the albumin–gamma$_2$-globulin ratio provides the most sensitive single index of the serum protein changes. Changes in the ratio appear to reflect the extent and activity of tuberculous infection and to mirror the recovery of the patient more closely than does the sedimentation rate.

Report of British Empire Cancer Campaign.—The annual report of the British Empire Cancer Campaign, which distributed over a million dollars for cancer research in 1955, has been published. At St. Bartholomew's Hospital, tobacco tar, tobacco tar plus dead tubercle bacilli, benzpyrene, and benzpyrene plus dead tubercle bacilli have been injected directly into the lungs of rats after thoracotomy. No tumors developed in the lung or the chest wall of the 10 rats injected with tobacco tar or the 9 injected with the tar plus dead tubercle bacilli, but, among the 9 injected with benzpyrene, one carcinoma and one sarcoma developed in the lung and one sarcoma arose in the chest wall at the site of the thoracotomy. The carcinoma developing in the lung as a result of benzpyrene injection is of added interest, as in this case the benzpyrene was dissolved in cholesterol, which the workers at this hospital found on histological examination to be present in increased amounts in the human lung where there has been any chronic inflammatory process. At the Royal Beatson Memorial Hospital, Glasgow, 5 mg. of cigarette-smoke tar and 0.25 mg. of resin from cigarette-smoke condensations dissolved in 0.2 ml. of arachis oil were injected into the right lung of 36 mice of mixed stock. The experiment was started in May, 1953, and all the mice are now dead. An adenocarcinoma developed in one mouse, in four others an adenoma developed in the right lung, and in one an adenoma developed in the left lung. As adenomas occur in about 20% of untreated mice over one year old, these tumors in the experimental mice are considered to be spontaneous.

Other Studies of Tobacco Tars.—At the Chester Beatty Research Institute, two experiments set up in order to test for carcinogenicity of cigarette tar, by its application to the skin of the mouse, were completed during the year. Both gave completely negative results. No malignant tumors were obtained, either with the whole cigarette tar or with the neutral fraction. In the experiment with the whole tar, one small papilloma appeared in the 21st month but had regressed three weeks later. These results are at complete variance with those of Wynder, Graham, and Croninger (1953). Equally negative results were obtained from injecting fresh cigarette tar subcutaneously into rats (no tumors after 20 months). Hamsters that had cigarette tar, either alone or mixed with soot, injected into the left bronchus, were tumor-free after 18 months. In other experiments, cigarettes made entirely from cigarette paper, in which chopped paper was substituted for tobacco, were smoked in the smoking machine, and the resulting tar was condensed. This tar, which is different in physical and chemical properties from cigarette tar, was shown by fluorescent spectroscopy to contain benzpyrene, but no tumors had arisen in 10 rats or 10 mice injected with the tar subcutaneously after one year. By means of the smoking machine, hamsters were exposed for five days a week to the entire smoke of 50 cigarettes daily, smoked at the rate of 6 an hour, for periods ranging from 12 to 20 months, without showing any tumor of the respiratory tract. In spite of the fact that their coats are stained yellow through exposure to the smoke, no skin tumors have developed. This agrees with Professor Passey's observation that life-long staining of the skin by tobacco smoke in man has never induced an epithelioma.

At Birmingham University, no skin tumors developed in a group of 50 mice painted twice weekly with a 20% solution of crude cigarette tar in acetone. Thirty mice survived 12 months and 12 survived 18 months. In another experiment, 30 mice were painted for one week with a 0.3% benzpyrene solution and subsequently painted twice weekly with the solution of tobacco tar. Four of them developed papillomas in the 18-month period, but no tumors occurred in this time in another group that received only benzpyrene. This suggests that the tar solution has a weak co-carcinogenic action. In a further series of animals given an initial treatment with tar followed by administration of croton oil weekly, only two small papillomas were obtained. This was to be expected from the application of croton oil alone. At the University of Leeds, 0.5 ml. of a solution containing 1 ml. of tar (the product of smoking 65 cigarettes in a smoking machine) in 50 ml. of arachis oil was introduced into the esophagus of 96 mice twice weekly for eight months. A control group of 96 mice were given the arachis oil alone, and an untreated group served as controls. No definite carcinoma of the lung had developed by the end of June. Eleven adenomas were observed: six in the experimental group, two in the arachis oil–treated group, and three in the untreated controls. Less than half the animals are still alive. In another experiment the tar was injected intratracheally into the lungs of a recently killed mouse. Incisions of the lungs after removal showed droplets of tar on the cut surface. Portions of the surrounding lung that contained droplets of tar were excised and implanted subcutaneously into animals of the same strain. No tumors developed at the site of injection.

At the Strangeways Research Laboratory, Cambridge, the effect of tobacco tar on human fetal lung tissue in vitro was studied. The neutral fractions of the condensate, obtained from individually smoked cigarettes, and tar from a smoking machine were used, the substances being suspended in serum. Doses containing about 0.014 gm. per milliliter of 3:4-benzpyrene revealed growth-promoting properties. After a fortnight's treatment, the condensate produced slight hyperplasia in 36% of the explants, but the smoking-machine tar induced more extensive hyperplasia in 62%. In contrast to benzpyrene, which induces hyperplasia in pneumomeres and bronchioli independently of their size, the growth-promoting effect of tobacco tars appeared mainly in the larger bronchioles. The hyperplasia consisted of increased proliferation of the bronchiolar lining, with enlargement of the cells and abnormal mitosis. At St. Bartholomew's Hospital, Finnish and Turkish cigarettes were found to have a very low arsenic content (0 to 5 mcg. per cigarette). Danish cigarettes, like British, American, Canadian, and Norwegian cigarettes, had a high arsenic content (60 to 90 mcg.). On the other hand, the small Danish cigars, or cigarillos, had a much lower arsenic content: 16 mcg. Italian cigarettes contained little or no arsenic: 0 to 1.5 mcg.

Soot.—At the Royal Beatson Memorial Hospital, Glasgow, soots from various sources were assayed for the presence of possible carcinogens. Railway engine soot, from funnels, yielded only trace amounts of 3:4-benzpyrene. In this regard, therefore, the railway engine is considered relatively unimportant as a source of air pollution. On the other hand, the gross particulate phase of diesel exhaust yielded 27% of acetone-extractable material, and a preliminary assay on the neutral fraction of this indicated the presence of an appreciable amount of 3:4-benzpyrene.

An examination of the case records of several hundred patients admitted to the Royal Marsden Hospital for cancer of the lung showed that in 422 men the average time in which smoking had been habitual was 39.3 years and the average age when smoking started was about 17 years.

Desoxyribonucleic Acid.—As formation of new desoxyribonucleic acid is known to occur exclusively in relation to mitosis and is considered to be the most significant event in the mitotic process, it has been presumed that the systems involved in desoxyribonucleic acid synthesis regulate the mitotic activity of tissues and that the malignant transformation might arise through irreversible changes in such systems. From studies of the duplication of desoxyribonucleic acid at mitosis as well as of various aspects of desoxyribonucleic acid biogenesis and catabolism, a possible relationship between the activity of nuclear desoxyribonuclease and the incidence of mitosis has been suggested. A histochemical approach seemed necessary in order to verify the conclusions drawn from studies with tissue homogenates. An attempt was therefore made at the Chester Beatty Research Institute to devise a method for localizing desoxyribonuclease in tissues. The general principle is to effect contact between a tissue section and a film of desoxyribonucleic acid, to allow sufficient time for the tissue desoxyribonuclease to act on its substrate in the film, and then to stain the unattached desoxyribonucleic acid remaining. Preliminary assays indicate that desoxyribonuclease can be localized in tissues by this method and that a satisfactory resolution can be attained.

Leukemia.—Resistance to busulfan (Myleran), in the sense of a specific refractoriness to the drug developing early in the course of leukemia, has not been seen in patients at the Royal Marsden Hospital who have been on maintenance therapy for long periods. After months or years, however, the activity of the disease gradually overcomes control by busulfan, although such control can sometimes be regained by increasing the dose. If busulfan is withheld, relapse is rapid, so that if another form of therapy is begun it should be given in addition to busulfan, which may later be withdrawn when control has been secured with the alternative therapy. It is reported that increasing numbers of patients with chronic granulocytic leukemia have now been treated continuously with busulfan for three or four years and for the most part have been in good health, living normal lives throughout. This is in contrast to the unstable state with recurrent relapse that occurs with conventional intermittent treatment by means of x-rays or drugs. Busulfan is as useful as any other drug used to treat chronic granulocytic leukemia and has definite advantages over the alternatives. It has yet to be shown, however, that radiotherapy followed by busulfan therapy is capable of prolonging life significantly.

At the Royal Marsden Hospital, 29 patients were treated with *p*-di-(2-chloroethyl)amino-L-phenylalanine, including 11 patients with Hodgkin's disease, four with lymphosarcoma, 13 with carcinoma, and one with malignant melanoma. The indications are that it will be of similar therapeutic value to *p*-di(2-chloroethyl) aminophenylbutyric acid in Hodgkin's disease and lymphosarcoma. In one of two patients with ovarian carcinoma, the rate of accumulation of ascitic fluid was slowed, and in the patient with carcinoma of the breast included in the series, skin recurrences regressed, although serous effusions were not influenced. The drug was of no benefit in cases of bronchial (7), gastric (2), or pancreatic (1) carcinoma or in malignant melanoma. It was given orally in doses of 2 to 10 mg. No gastrointestinal side-effects were encountered, but patients who received the larger doses developed severe thrombocytopenia and neutropenia; however, they recovered rapidly from this when the drug was withdrawn.

Miscellaneous.—Eight children with verified neuroblastoma were treated at the Hospital for Sick Children, Great Ormond Street, with massive doses of cyanocobalamin, with injections of 1,000 mcg. on alternate days, the course being maintained for from two to two and one-half years where survival permitted. Of the first 19 patients treated, 6 were alive and well two to five years after the onset of the disease. Two of these survivors received only a short course in conjunction with operation and radiotherapy, but in the rest the response could be attributed to the cyanocobalamin—a survival rate of 25%. In addition to these long-term survivals, definite but temporary regression of the tumor was observed in four children and similar regression was apparent in two who were still under treatment. Thus, the administration of cyanocobalamin has led to temporary or lasting arrest of tumor growth in nearly 50% of the patients The frequency with which regressive phenomena were noted indicates that this is a therapeutically induced and not a spontaneous effect.

A report from the department of radiotherapeutics at Cambridge indicates that intravenous administration of menadiol sodium diphosphate has a small but useful effect as a radiosensitizer in the radiotherapy of inoperable carcinoma of the bronchus. Although the effects are not spectacular, the results suggest that it is possible to improve the response of some human malignant tumors to radiotherapy by means of chemical radiosensitizers. A report from Harefield Hospital, Middlesex, gives details of an experiment to evaluate the effect of repeated administration of cortisone on the development of radiation damage in normal and malignant tissues of guinea pigs and mice. To date, the results indicate that the administration of 20 mg. of cortisone is more effective in reducing the damage to heavily irradiated skin when given daily for 21 days, beginning three weeks after irradiation, than when given before irradiation or daily for the 21 days immediately after radiation.

In the field of diagnostic radiology, positive correlation between the ultrasonic findings and the results of ventriculography and arteriography has been achieved in a number of cases of calcified tumor, astrocytoma, and glioma of certain areas of the brain. From a study of 265 intracranial tumors occurring in children, a new classification of such growths has been evolved at the Hospital for Sick Children, Great Ormond Street. This has proved to be both simple and prognostically significant. From this point of view, the worst types of tumor are the differentiating medulloblastoma and the diffuse astrocytoma, both of which appear to be universally hopeless. The cerebellar nodular astrocytoma gives the best prognosis. Although a longer follow-up will be necessary for certainty of an improvement in the management of these diseases, it would seem that such has possibly been the case in regard to the subtentorial astrocytoma, meningioma, and subependymal glioma.

At the Middlesex Hospital, a study of 80 patients with mucous gland tumors other than those of the major salivary glands has confirmed the fact that the prognosis of these tumors in such places as the palate, lip, and nose is worse than in the parotid, partly because of the increased frequency of the characteristically infiltrative basaloma and partly because of the increased difficulty of diagnosis and radical resection in some of these locations. Although the basalomas may show a good initial response to radiotherapy, recurrence always eventually takes place.

Bacillary Dysentery.—Dr. R. I. Hutchinson (*Month. Bull. Min. Health* 15:110, 1956) reported on the bacteriological examination of the bedclothes, patients' clothes, toys, dust, floor, floor brushes, furniture, walls, door handles, toilet seats, and lavatory floors in two residential nurseries during three outbreaks of Sonne dysentery—in the infants' department of a primary school during one outbreak, in one private house in which two families lived and in which 10 of 12 occupants were excreting Shigella sonnei, and in the nursery of a colony for mental defectives in which cases of diarrhea were occurring.

The results suggested that there is not a very great scatter of organisms into the environment from an infected person. Of 21 positive swabs from over 450 collected, 12 were from places or articles closely associated with the disposal of feces: the toilet seat, the lavatory floor, and chamber-pots; 4 were from clothes or bedding in intimate contact with a child passing frequent loose stools; and the remaining 5 were from dust in the vicinity of lavatories or from toys being handled by sick children. Of 34 toilet seats swabbed in houses or institutions in which there was a known excreter of S. sonnei, 11 were contaminated with this organism: 24 swabs were taken in institutions and 6 of these were positive; 10 were taken in private houses and 5 of these were positive. Blotting-paper patterns of the seats of 17 lavatories were made, and each one was placed over the original. A solution of gentian violet was emptied into the pan and flushed. In every case, macroscopically visible splashes appeared on the blotting paper. This experiment was repeated with a specimen of formed feces, a specimen of formed feces thoroughly triturated with broth, 5 ml. of an overnight broth culture of S. sonnei, and 100 ml. of heavily positive fluid feces. Only with this last sample were positive results obtained when the splashes were cultured. In other words, contamination of the toilet seat is likely to occur from flushing only in the early stage of the acute illness when heavily positive fluid stools are being passed.

Of 37 children observed while at stool, 17 handled the seat with either one or both hands while settling themselves on it. Six of these 17 children touched their face and mouth to a greater or lesser degree or sucked their fingers, thus transferring organisms from the toilet seat to the mouth. Hand swabbing after the children had visited the toilet for micturition, but before hand washing, no child having defecated immediately prior to the swabbing, gave the following results: In a primary school, during the seventh week of an outbreak, 2 of 118 children swabbed gave positive results. In two day nurseries, during the second and fifth weeks of an outbreak, no positive swabs were obtained from a total of 75 pairs of hands. In another day nursery, during the second week of an outbreak, 17 positive swabs were obtained from 35 pairs of hands. In a private house, the surprise swabbing of three asymptomatic children while at play produced positive swabs from the hands of a 5-year-old girl whose stool had been positive three days previously. Experimental contamination of the fingers in the laboratory showed that the organisms remained alive on the fingers for about three hours. The permeability of toilet paper was investigated by wrapping double thickness of the paper over the fingers, which were then pressed lightly on to solid, semisolid, and fluid stools for a few seconds. Five different types of paper were used, including two proprietary disinfectant brands, and in every case organisms penetrated through to the fingers with the fluid and semisolid stools. With the solid stools, 80% of the papers allowed the passage of organisms through to the fingers. It was found that S. sonnei could survive on a wooden toilet seat in a public lavatory for 17 days when the number of organisms in the contaminating drop was above 27,000 and for 3 days when the number of organisms deposited was 14,000. Less than 10,000 organisms died out in 24 to 48 hours. This was under conditions of light, temperature, and relative humidity occurring in a lavatory in daily use by the public.

Further investigations indicated that the survival time of S. sonnei outside the human body is increased by the absence of light and the presence of a low temperature and a high relative humidity but that an increased temperature, in spite of a high relative humidity, greatly curtails it. This suggests that the conditions found in many lavatories favor the survival of S. sonnei when contamination of inanimate objects occurs but that soiling of the perianal skin and the clothes in intimate contact with the body will not result in a long survival of the organisms, owing to the body temperature and skin humidity. It is therefore recommended that lavatories be placed in a brightly lighted, warm, and sunny position in all new constructions. As contamination and subsequent handling of the toilet seat and the use of easily permeable toilet paper are probably major factors in the spread of S. sonnei in private houses and institutions, the elimination of these hazards by proper placing of lavatories would do much to prevent spread of the organism, and thereby reduce the severity of epidemics.

CORRESPONDENCE

WHOLE BLOOD CLOTTING

To the Editor:—Certain aspects of the article "Effect of Bishydroxycoumarin (Dicumarol) on Clotting Time of Whole Blood" by Mayer and Connell in THE JOURNAL, June 30, page 806, merit further discussion. Until the appearance of this paper, there were serious questions about the rationale of Dicumarol usage. The general opinion had been that it did not affect significantly the clotting time of whole blood. Previous attempts to show changes in clotting time had given contradictory or inconclusive results. Accordingly, the question persisted, "If Dicumarol doesn't change the clotting time in the dosage given, how can one be sure it is an anticoagulant?" Because this question went unanswered, the argument for Dicumarol was weakened, and I believe that as a result many physicians were reluctant to use this drug. The details were discussed by me in a recent review article (*Am. J. M. Sc.* 229:534 [May] 1955).

The report by Mayer and Connell, however, now answers this question. These authors showed clearly that Dicumarol does increase the clotting time of blood under conditions of clinical usage, as measured by an accurate technique, but that the latent period before attainment of the peak effect on clotting time is 10 days. Also, they showed a poor correlation between prothrombin time and coagulation time. This probably explains why earlier studies did not reveal an effect on clotting time: measurements were performed too soon after the onset of therapy. Very likely, the findings of Mayer and Connell also explain the troublesome anomalies in Dicumarol therapy, i. e., the occurrence of thrombosis at low prothrombin percentages and bleeding at prothrombin levels considered safe. In addition, they suggest a possible way to avoid these situations by using their standardized clotting time measurement, and by employing heparin until the standardized clotting time has reached 15 minutes. It is hoped that their technique for control of coumarin-derivative therapy will prove to be entirely satisfactory for general adoption in clinical medicine. On numerous occasions it has been found that some techniques, while satisfactory in the hands of the original investigators, are too difficult for others to reproduce. However, even if their method of measuring the clotting ability of the blood is not widely adopted, their findings are highly significant, in that they show that Dicumarol in clinical doses does increase clotting time. By answering the most serious objection to Dicumarol therapy, Mayer and Connell have greatly strengthened the argument for this type of treatment, and their report should go far toward overcoming the reluctance of many physicians to use Dicumarol where adequate laboratory facilities are available.

TOXIC EFFECTS OF AMMONIUM CHLORIDE

To the Editor:—The recent article by Sievers and Vander, "Toxic Effects of Ammonium Chloride in Cardiac, Renal, and Hepatic Disease" (*J. A. M. A.* 161:410 [June 2] 1956) and the recent extremely informative review by S. P. Bessman, "The Role of Ammonia in Clinical Syndromes" (editorial, *Ann. Int. Med.* 44:1037, 1956) point up the importance of ammonia in the production of toxic cerebral effects in cardiac, renal, and hepatic disease. Although the article of Sievers and Vander refers to the production of toxic cerebral effects after treatment with ammonium chloride, it is now known that the blood ammonia level is elevated in certain patients with heart failure, even without treatment with ammonium chloride (Bessman, A. N., and Evans, J. M.: *Am. Heart J.* 50:715, 1955). These workers showed a parallelism between the blood ammonia level and the mental state. It is generally held today that the state of hepatic coma is produced, in part at least, by the accumulation of ammonia in the blood due to the inability of cirrhotic patients to clear ammonia from their blood (Phillips, G. B., and others: *New England J. Med.* 247:239, 1952; McDermott, W. V., Jr., and Adams, R. D.: *J. Clin. Invest.* 33:1, 1954).

Sodium glutamate has been suggested by Walshe (*Lancet* 1:1075, 1953) as a therapeutic agent in hepatic coma. According to Bessman (*Ann. Int. Med.* 44:1037, 1956) this substance could prove helpful in two ways: (1) by combining with ammonia to form glutamine, which transports ammonia to the kidney for excretion, and (2) by transamination with pyruvic acid to form alpha-ketoglutaric acid, an intermediate of the Krebs cycle. It has been noted by many investigators that glutamate is not uniformly successful in hepatic coma (McDermott, W. V., Jr., and others: *New England J. Med.* 253:1093, 1955). It seems important to speculate why this is so. The synthesis of glutamine proceeds in homogenates of liver, kidney, or brain, provided adenosine triphosphate (ATP) is supplied as a source of high-energy phosphate bonds (Weil-Malherbe, H.: *Physiol. Rev.* 30:549, 1950). The reaction is formulated by the equation:

$$\text{Glutamic acid} + NH_3 + ATP \rightarrow \text{glutamine} + ADP + \text{inorganic phosphate.}$$

It is known that glutamic acid inhibits the anaerobic glycolysis of brain slices (Krebs, H. A.: *Biochem. J.* 29:1951, 1935). Weil-Malherbe (referred to above) believes that this phenomenon may be due to a competition between glucose and glutamic acid for available adenosine triphosphate, and accordingly the inhibition is reversed by its addition. Thus the presence of adenosine triphosphate may be the limiting factor regardless of whether glutamic acid may be of benefit in hepatic coma or in the other states where toxic actions from ammonia may cause cerebral symptoms. Glutamic acid alone may actually be harmful if excess adenosine triphosphate is not available, according to Weil-Malherbe's theory.

Recently, I treated two cardiac patients who developed mental symptoms (confusion, stupor, disorientation) associated with long-continued use of ammonium chloride. At first the results were poor after treatment with glutamic acid (L-Glutavite) for 72 hours. When adenosine-5-monophosphate (A_5MP) was added (100 mg. in gel intramuscularly daily) the response was phenomenal within four to six hours of the first dose. The glutamic acid treatment was continued. It has been shown that the injection of A_5MP causes a significant increase in the body stores of adenosine triphosphate (Albaum, H. G., and others: *J. Clin. Invest.* 30:525, 1951). In the two cases referred to above, the treatment was continued for five days with a very satisfactory result. Likewise, in one case of hepatic coma in which the patient was treated with glutamic acid given intravenously, with indifferent results over a 36-hour period, there was arousal from coma when A_5MP was given according to the technique described above. In another case of metastatic carcinoma of the liver with coma, presumed to be hepatic in nature, injections of A_5MP in the above noted dosage roused the patient from coma for several days. Subsequently, of course, the patient died from his disease. No glutamic acid was given this patient. In summary, in the toxic states caused by ammonium, besides glutamic acid, excess of adenosine triphosphate is necessary for the ammonia to be cleared, and a lack of this substance could explain some of the failures with glutamic acid reported in the literature.

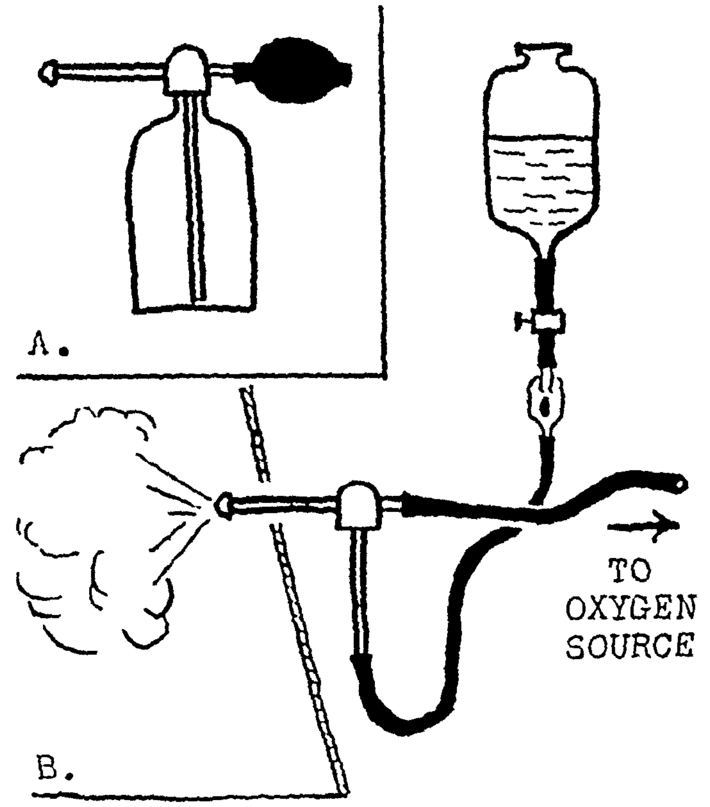
SIMPLE DEVICE FOR PROVIDING HUMIDIFIED OXYGEN

To the Editor:—"Cold steam" is an important adjunct to the treatment of croup, severe pneumonia, and several other conditions. Because commercially constructed steam tents are not always at hand, a number of substitutes are in common use. The following method is suggested because of its simplicity, inexpensiveness, and accessibility. The bottle and rubber bulb are removed from any ordinary atomizer that is capable of producing a sufficiently fine spray (see figure, *A*). By means of rubber tubing, the oxygen supply is joined to the inlet from which the bulb was removed. A water reservoir is connected to the fluid inlet tube of the atomizer head through a drip chamber. This permits the flow of water and that of oxygen to be regulated independently. The nozzle of the atomizer is then introduced through an opening in the tent.



A, satisfactory type of atomizer; *B*, assembled apparatus.

This apparatus (see figure, *B*) has been found more stable and easier to regulate than other such devices. As with any oxygenating equipment, one must be careful to see that all onnections are tight. The flow of water and of oxygen should e inspected periodically. In addition, one should not allow the ater reservoir to become empty, for this would permit the entrance of air.

TREATMENT OF EARLY MAMMARY CANCER

To the Editor:—The guest editorial "Treatment of Early Mammary Cancer" (Elman, R.: *J. A. M. A.* 161:972 [July 7] 1956) deserves commendation. The author wisely points out that the optimum treatment for early carcinoma of the breast is surgical removal while the disease is still confined to the breast. Since this, unfortunately, is not always possible, "the most that should really be claimed for therapy in cancer is significant and sometimes gratifying prolongation of life." The author has some strictures on simple mastectomy combined with radical postoperative radiotherapy that deserve comment. First, he questions whether there is supportive evidence in favor of the Edinburgh program. If he will glance at my article published in the *American Journal of Roentgenology* (72:923 [Dec.] 1954), he will see reports on 458 cases treated by such method (elsewhere than in Edinburgh) with five-year survival rates comparable to the excellent figure reported by McWhirter. Second, he quotes an evaluation of the Edinburgh method recently published by Ackerman, which does not perhaps give all the facts. Careful reading of Ackerman's report shows that the "considerable radiation morbidity" consisted of undesirable reactions in 47 of 1,882 cases, a morbidity rate of 2.5%. A little inquiry would have revealed that most of these cases had been treated during the early World War II years, when the staff was depleted and treatments were frequently interrupted by air raids. Every experienced physician knows that radical surgery also carries a morbidity rate that is occasionally quite disabling. Next, Ackerman reportedly noted a relatively high persistence of disease in the radiated cases. Well, there is unfortunately also a relatively high persistence of disease in the surgically treated field, if one considers the entire thorax; approximately one-third of persons surviving radical mastectomy 5 years unfortunately die from breast cancer before the 10th year, and additional numbers continue to die of the disease in ensuing decades. This problem exists in any therapeutic method in this particular type of cancer.

Finally, the writer of the editorial quotes Ackerman as noting no objective evidence of sterilization of lymph nodes containing cancer. A little reflection should show that this is not surprising, since the nodes ordinarily removed for study at a late stage are precisely those that have failed to respond to treatment. The hard, fixed supraclavicular and high axillary nodes of other cases that have disappeared under proper radiotherapy will not ordinarily be excised. Incidentally, McWhirter and other radiotherapists do not claim that radiotherapy sterilizes cancer in treated lymph nodes in all cases. Perhaps the most remarkable feature of the visit of this distinguished pathologist to Edinburgh was the fact that, for the first time in international cancer study, a visiting expert confirmed the diagnosis of cancer in over 98% of a series of almost 2,000 consecutive patients subjected to a given treatment program. This is a unique episode in cancer study. There are many areas in the United States where qualified radiotherapists are now readily available to patients with early mammary cancer; the evidence from Edinburgh and other sources shows that there are two effective alternate methods of treating such cases. These are (*a*) radical mastectomy, as the writer of the editorial proposes, and (*b*) simple mastectomy plus radical postoperative radiotherapy. In some hands the five-year survival rate is slightly improved by the latter program, which, incidentally, is applicable to the vast majority of patients presenting themselves for treatment, in contrast to the radical program, which is strictly applicable only to those with disease in clinical stage 1 or 2.

THE AUTOPSY

To the Editor:—The letters and comments provoked by Dr. Starr's guest editorial (*J. A. M. A.* 160:1144 [March 31] 1956) testify to the sharpness of his criticism of current postmortem practice. There can be little doubt that, to the extent that university departments of pathology fail to apply modern techniques and investigative attitudes in the assay of autopsy material, Starr's dim view of the "routine" autopsy is justified. However, neither Starr's editorial nor the comments that it elicited make mention of the autopsy in nonuniversity hospitals, where the vast majority of postmortem examinations are conducted. In the state of Connecticut, by last available report, 605 autopsies were performed at the University Hospital, in contrast to more than 3,000 autopsies in 20 nonuniversity hospitals. In eight of the latter, which had no training program in pathology, an estimated 700 autopsies were reported. In the 12 other hospitals where accredited residency training programs in pathology were operative, there were 2,300 postmortem examinations. Deficiencies of budget and staff and of instrumentation and technical skills in most nonuniversity pathology departments make it virtually impossible for postmortem examinations to be pursued on the experimental plane that Starr advocates. Even though unhappily this may be so, the autopsy in these institutions still fulfills other important ends, which he mentions only cursorily.

In the hospital with neither university affiliation nor resident training program, the autopsy may be performed simply with a view to determining, if possible, the cause of death or to provide a spot check on the diagnostic accuracy of the clinical staff. Even these limited objectives have their value. In the nonuniversity hospital with a training program in pathology, these objectives are also fulfilled, but, in addition, the so-called routine autopsy provides cumulative experience for the trainee. Of greater importance, it presents an opportunity to reconstruct the progress of the disease state from its incipiency to its culmination on the postmortem table, taking into account all of the available historical and clinical data. Each autopsy becomes a stimulating exercise in the understanding of the genesis, flowering, and end-result of the disease state. This is dynamic pathology in its conceptual sense, and for this complicated instrumentation is not essential. However much pathologists may desire to utilize available modern experimental techniques in their autopsy investigations, most pathologists, and the majority of them are located in nonuniversity institutions, view the belabored "routine" autopsy as an opportunity to increase their own store of knowledge and, through programed conferences, to transmit their findings to their clinical colleagues. This is a good that requires no defense and no apology.

GRANULOMA OF AXILLAS

To the Editor:—A preliminary report on the suspected cause of an unusual eruption on the axillas of women is worthwhile for diagnosing and possibly averting this new disease. Since the presentation of two cases at the Chicago Dermatological Society meeting on May 16, 1956, our colleagues have been seeing similar cases. In our series of four cases, women in the middle-age group were affected. The eruption was limited to the axillas, particularly the hairy area. The lesions were papules and nodules, with the highest point resembling a vesicle. Fluid was not obtained from the pseudovesicles. Clinically, the eruption was unlike any cutaneous disease, common or uncommon, previously seen on the axillas. For this reason, a biopsy was performed on three patients and repeated on the first one several weeks later. Histopathological findings were those of a tuberculoid reaction, suggesting the presence of a foreign body. The sections suggested the features of a silica or talc granuloma. In our cases, the source of the foreign body was probably the introduction of some substance into abraded areas, caused by shaving the axillas. This probably occurred when a stick deodorant containing zirconium was applied once or twice daily on the skin of the axillas.

We now suspect that the cause of this unusual eruption on the axillas is zirconium, a metallic element similar to titanium and silicon. The history of contact with a stick deodorant containing zirconium is common to all four women, and it is a reasonable explanation for the localization of the eruption on the axillas. The course of the disease is unknown to us at this time. Gradual improvement of the eruption in the first patient leads us to believe that spontaneous cure, although slow, is likely.

FOREIGN BODY OF LONG STANDING

To the Editor:—A native of Scotland, who has lived in the United States for many years, has been under my observation for about 10 or 12 years, principally for recurrent episodes of pneumonitis, which were presumed to be initiated by a chronic bronchiectasis. These attacks would occur at least every six months and seemed to be of increasing severity. The patient recalled that she always "took pneumonia" easily, and she remembered her chronic productive cough as ever-present from early childhood. In the interim she married and raised three children, submitted to a cholecystectomy for cholelithiasis and cholecystitis, and was hospitalized once for a bronchoscopic examination, which was not performed because she had no sputum after a period of observation of 48 hours. Since she has been under my care I have suggested many times that a bronchoscopic examination would be enlightening, but, for some reason not clearly understood at this time, the examination was never performed. With the advent of antibiotics, her episodes of pneumonitis, while severe in the early stages, responded rapidly to therapy, and the need for more intensive investigation of the cause of the disorder seemed increasingly less important to the patient—and, I might add, to her medical consultant as well.

On Jan. 7, 1955, this patient suffered a violent paroxysm of coughing, during which marked dyspnea was present with cyanosis; as she described it, "I felt surely I could not ever breathe again." Finally, with a superphysical effort she expectorated a foreign body, which can be seen in the accompanying illustration. It resembled a piece of charcoal and was not particularly fragile. Upon further consideration the patient recalled an incident occurring in Scotland when she was 5 years of age. She was playing one day and eating beechnuts at the same time. She distinctly recalled choking on a beechnut kernel, after which she had labored breathing; her cough with the subsequent symptoms for 63 years dated from that time. For several days after expectorating this charred mass she had mild hemoptysis, but she has been asymptomatic since being free of annoying cough for the first time in 63 years. I have not searched the literature on the subject, but it seems that this case of a foreign body of this type remaining undetected in a bronchus for so many years must establish some sort of record.

THE AUTOPSY

To the Editor:—The letters and comments provoked by Dr. Starr's guest editorial (*J. A. M. A.* 160:1144 [March 31] 1956) testify to the sharpness of his criticism of current postmortem practice. There can be little doubt that, to the extent that university departments of pathology fail to apply modern techniques and investigative attitudes in the assay of autopsy material, Starr's dim view of the "routine" autopsy is justified. However, neither Starr's editorial nor the comments that it elicited make mention of the autopsy in nonuniversity hospitals, where the vast majority of postmortem examinations are conducted. In the state of Connecticut, by last available report, 605 autopsies were performed at the University Hospital, in contrast to more than 3,000 autopsies in 20 nonuniversity hospitals. In eight of the latter, which had no training program in pathology, an estimated 700 autopsies were reported. In the 12 other hospitals where accredited residency training programs in pathology were operative, there were 2,300 postmortem examinations. Deficiencies of budget and staff and of instrumentation and technical skills in most nonuniversity pathology departments make it virtually impossible for postmortem examinations to be pursued on the experimental plane that Starr advocates. Even though unhappily this may be so, the autopsy in these institutions still fulfills other important ends, which he mentions only cursorily.

In the hospital with neither university affiliation nor resident training program, the autopsy may be performed simply with a view to determining, if possible, the cause of death or to provide a spot check on the diagnostic accuracy of the clinical staff. Even these limited objectives have their value. In the nonuniversity hospital with a training program in pathology, these objectives are also fulfilled, but, in addition, the so-called

Rupture of the Heart After Myocardial Infarction. J. F. Maher, G. K. Mallory and G. A. Laurenz. New England J. Med. 255:1-10 (July 5) 1956 [Boston].

At the Mallory Institute, the pathology department of the Boston City Hospital, interest in cardiac rupture as a fatal complication of myocardial infarction was renewed by the observation of several such cases in rapid succession. This suggested an increased frequency of this complication and raised the question whether the newly introduced therapeutic methods favor cardiorrhexis. Recent or healing myocardial infarction was found in 183 of 1,928 autopsies during the two years ending June 30, 1954. Clinical histories were available in 178 of the 183 patients, and 21 patients with cardiac rupture were found among the 178 reviewed clinically. Eleven of the patients were men and 10 were women. Earlier reports also indicate that cardiac rupture occurs as often in women as in men, despite the prevalence of myocardial infarction in men. About half of the ruptures occurred during the first five days after the onset of chest pain due to myocardial infarction. Cardiorrhexis occurred in only 2 of the 66 hearts (3%) that, in addition to acute infarction, showed an old healed myocardial infarct, whereas there were 19 cardiac ruptures in 117 patients (16.2%) who had only acute or healing myocardial infarction. This agrees with earlier observations that myocardial fibrosis is much less common in infarction that terminates in cardiac rupture.

There were 123 patients who had some evidence of congestive failure, and 7 (5.7%) of these hearts ruptured, whereas of the 50 hearts not in failure 14 (28%) ruptured. Treatment with diuretics, antibiotics, or digitalis could not be considered responsible for the recent higher frequency of cardiac rupture. It may be expected, however, that the injudicious use of levarterenol or anticoagulants or the abuse of the bed-and-chair regimen might result in rupture of the heart. Prevention appears to be the only solution to the problem of cardiac rupture. Rest must be emphasized during the early period after infarction, when the diagnosis is being established. Hypertensive patients and those who have no evidence of heart failure in particular must be kept at rest if rupture is to be prevented.

The Distribution in England and Wales of Mortality from Coronary Disease. W. J. Martin. Brit. M. J. 1:1523-1525 (June 30) 1956 [London, England].

The rapid rise of mortality attributed to coronary disease during the past 30 years has been one of the chief features of the vital statistics of England and Wales. This report is concerned chiefly with the trend of mortality from coronary disease during the last 15 years. It is shown that at ages of 35 and over a twofold to threefold increase has occurred in England and Wales in the death rates attributed to coronary disease during this 15-year period. The death rate in males has increased more rapidly than that in females at the younger ages, 35 to 54 years. The regional distribution of deaths attributed to coronary disease is not very different from that of deaths from all causes, the death rates being highest in the northern counties. For both sexes mortality is high in the urban areas as compared with the rural, but the difference is more distinct for males. Although the 1951 analysis of mortality (1% sample) showed a steep gradient for mortality from coronary diseases with social class, the geographical differences in the mortality ratios in 1950 to 1952 cannot be explained by variations in the social class structure of the populations at risk. The proportion of males in social classes 1 and 2 in different areas was not correlated with the level of their mortality ratios, and it seems that some other characteristics must be responsible for the widely varying level of mortality in the different areas. In each type of area—county borough, urban district, and rural district—there was close correlation between the male and female standardized mortality ratios from coronary disease.

Serum Transaminase: New Aid in Diagnosis of Coronary Thrombosis and Hepatic Affections. N. U. Bang, K. Iversen and S. Madsen. Ugesk. læger 118:599-605 (June 2) 1956 (In Danish) [Copenhagen, Denmark].

In human serum, measurable amounts of transaminase are constantly demonstrable. Serum transaminase activity is increased in various disease conditions. Special interest attaches to the course of the reaction in acute myocardial infarct and diseases of the liver. Increased values are not found in infectious diseases, malignant diseases, metabolic diseases, or degenerative diseases when acute tissue degeneration is not present in the myocardium, skeletal musculature, or liver parenchyma. The values are considerably increased in acute myocardial infarct, rheumatic fever with active myocarditis, and especially in hepatic affections with parenchyma injury. The preliminary reports indicate that the glutamic oxalacetic transaminase increase in acute hepatitis begins as early as in the preicteric phase and seems to follow and mirror the clinical condition. According to a preliminary report, a moderately increased transaminase activity is found in occlusion jaundice as long as the occlusion lasts. Three cases, two in patients with coronary thrombosis and one in a patient with acute hepatitis, showed characteristic curves.

Pneumonia and Bronchopneumonia Treated by Sulfamides and Antibiotics. H. Durieu, F. de Clercq, A. de Coster and others. Acta clin. belg. 11:105-131 (March-April) 1956 (In French) [Brussels, Belgium].

The authors studied the therapeutic results obtained with sulfamides and antibiotics in patients with pneumonia and bronchopneumonia from records of the Clinique Médicale covering a 25-year period. Conclusions can have only an indicative value because of the disparities of the considered series and the unequal conditions of observation. The records examined were of 468 patients with pneumonia and 390 with bronchopneumonia. Of the patients with pneumonia, 126 were treated by sulfamides, 165 by antibiotics (usually penicillin), and 177 (the control group) by neither. The mortality rate in the control group was 30%, in the sulfamide-treated group 20%, and in the penicillin-treated group 5%. The seriousness of both diseases increases with age. Uremia indicates a poor prognosis, while leukocytosis seems to have little bearing on prognosis. No influence on prognosis is exerted by blood eosinophilia during the febrile phase of illness. It was encountered in 25% of the control group cases, in 13% of the sulfamide group, and in 57% of the antibiotic group. It was found in 80% of all 468 patients during convalescence. The mortality rate was higher when the patients were treated late in the course of the disease, this being especially true in those who were treated by sulfamides. Treatment during the first two days of illness seems to be a crucial factor in the mortality rate. Duration of the febrile phase is shortened in some of the patients treated with sulfamides or, especially, antibiotics. By the fourth day of illness 13% of the antibiotic-treated patients were apyretic, while only 4% of the control group and 4% of the sulfamide-treated group were apyretic at that time. Shortening of the duration of fever is the most obvious benefit derived from the antibiotics. Small doses (200,000 U.) seemed as active as the moderate (400,000 U.) or larger (1 million or more U.) doses

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

of penicillin. Signs of pulmonary consolidation regress a little more rapidly in treated patients, but by the third week the three categories of subjects had approximately the same (14-16%) proportion of significant pathological phenomena. Serious infectious complications, both local and distant, are less frequently observed in patients treated with penicillin. The use of large doses of penicillin is not justified, as the pneumococcus remains almost entirely sensitive to this drug. The fear among doctors of a regularly increasing resistance of the pneumococcus to penicillin is not verified by the findings of bacteriologists.

According to their records, the 390 patients with bronchopneumonia were divided into a control group of 254, a sulfamide-treated group of 35, and an antibiotic-treated group of 101. Since the sulfamide group was so small, valid comparisons are difficult and will have a very relative value. The mortality rate in the control group was 55%, in the sulfamide group 26%, and in the antibiotic group 16%. Although uremia is an ominous sign for prognosis, leucocytosis does not seem to have prognostic value. Contrary to the case in pneumonia, blood eosinophilia during the acute phase in bronchopneumonia seems favorable. Treatment with sulfamides and antibiotics moderately shortens the duration of fever, this effect being more evident with penicillin. Infectious complications are tremendously decreased by treatment with sulfamides and still more by antibiotics. The bronchopneumonia records showed 30% failures after treatment with sulfamides and antibiotics, whereas the pneumonia records showed 14% failures after these treatments. It is likely that the characters of the causal micro-organisms and the fragility of the host explain the high rate of failures in the bronchopneumonia cases. Penicillin may be used routinely in the beginning of the treatment, but it must be quickly replaced by a wider-range antibiotic if a therapeutic effect is not obtained after a few days of treatment.

Quantitation of the Activity of Rheumatoid Arthritis: 2. Recession of Morning Stiffness as Patients Go into Remission. J. Lansbury. Am. J. M. Sc. 232:8-11 (July) 1956 [Philadelphia].

Morning stiffness is an exceedingly common manifestation of active rheumatoid arthritis at all ages. A review of 100 consecutive cases showed that it was present in 97% of these patients at the time of the initial interview. Morning stiffness can be quantitated by observing its duration rather than its intensity. Most patients can readily distinguish stiffness from pain, and they can generally accurately identify its duration after rising in the morning. This paper considers "duration of morning stiffness" as it relates to the over-all activity of rheumatoid arthritis. The data presented were collected from records extending over a period of 10 years. The records of 45 patients personally observed by the author indicated that the average duration of morning stiffness at the time of the first office visit was 3.5 hours. There was a correlation between duration of morning stiffness and activity of the disease as measured by the sedimentation rate of erythrocytes, but the duration of morning stiffness appeared not to be related to age, sex, duration of disease, or hemoglobin concentration. The author presents three graphic analyses, which indicate that hours of morning stiffness decline in a regular trend as the patient goes into a remission. Duration of morning stiffness is, therefore, a valid index to the general or fibrositic component of rheumatoid activity and so deserves to be routinely recorded in progress notes.

Quantitation of the Activity of Rheumatoid Arthritis: 3. The Maximum 5-Minute Cutler Sedimentation Rate as an Index. J. Lansbury. Am. J. M. Sc. 232:12-16 (July) 1956 [Philadelphia].

The sedimentation rate has been accepted as a rough guide to the degree of systemic activity in cases of rheumatoid arthritis. Various methods for performing the test are in vogue, such as the Cutler, Westergren, Wintrobe, and Rourke-Ernstene techniques, but the results obtained with these various methods cannot be compared, since their values, for both the normal and the abnormal, differ from one another. The author uses the Cutler method, which differs from the others in that a wide-bore tube is employed. The graph obtained with the Cutler method furnishes two types of information: (1) the total fall of erythrocytes at the end of one hour, and (2) a series of 5-minute decrements that produce a curve from the starting point at zero to the 60-minute end-point. The shape of this curve gives information not apparent from the 60-minute end-point alone. The author has for years used the five-minute index as a measure of the activity of rheumatoid arthritis.

The maximum five-minute fall of erythrocytes observed by the Cutler sedimentation technique averaged 5.6 mm. in a series of 100 consecutive patients with rheumatoid arthritis at the time of their first interview. A statistical analysis of the five-minute erythrocyte sedimentation rate in 10 patients with rheumatoid arthritis going into remission indicated a trend toward normal, both for individuals and for the group, which is sufficiently regular to validate the Cutler five-minute erythrocyte-sedimentation rate as a quantitative index of systemic rheumatoid activity. Other sedimentation methods, such as the Rourke-Ernstene and Westergren, deserve to be similarly evaluated.

Rheumatoid Spondylitis and Aortic Insufficiency. D. P. Schilder, W. P. Harvey and C. A. Hufnagel. New England J. Med. 255:11-17 (July 5) 1956 [Boston].

The authors studied a large number of patients with aortic insufficiency who were being evaluated for surgical correction of this lesion. Rheumatoid spondylitis was present in 5 of the first 100 seen. These cases illustrate the association of rheumatoid spondylitis and aortic insufficiency and present some unusual features. The patients were remarkably similar in many respects. None had a history of syphilis. Only one had definite rheumatic fever, and one had peripheral rheumatoid arthritis. The heart disease and aortic insufficiency were severe; three patients died of it. All had free aortic insufficiency and hypertrophy of the left ventricle, and four had first-degree atrioventricular block. The rheumatoid spondylitis was advanced, and all patients were symptomatic with elevated sedimentation rates; two were anemic. There was an interval of many years between the onset of the spinal disease and clinical heart disease. Postmortem study in two patients showed aortic valves that were insufficient, thickened, and shortened, with fibrosis at the base but without commissural irregularity or obliteration. There was involvement of all layers of the aortic root, with intimal calcification in one patient. The mitral valves were normal, and no Aschoff bodies were discovered. It may be that rheumatoid spondylitis, a collagenous disease in the broad sense and closely allied to rheumatic fever and rheumatoid arthritis, occasionally causes heart disease with a predilection for the aortic valve, where it produces endocarditis and valvulitis. This would support the concept of a close relation between these diseases.

Changes in Concentration of Blood Lipids Following Prolonged Administration of Large Doses of Nicotinic Acid to Persons with Hypercholesterolemia: Preliminary Observations. W. B. Parsons Jr., R. W. P. Achor, K. G. Berge and others. Proc. Staff Meet. Mayo Clin. 31:377-390 (June 27) 1956 [Rochester, Minn.]

Diets low in fat content, administration of desiccated thyroid, use of certain vegetable sterols such as sitosterol, and administration of large doses of estrogens have been used to correct abnormal lipid metabolism when it is found in association with clinical atherosclerosis. Each of these procedures has resulted in partial or complete correction of the disturbed lipid metabolism in some patients, but frequently the results have been disappointing. The search continues for a simple, safe, and effective method of correcting abnormalities of lipid metabolism, although admittedly there is no positive evidence that such therapy would prevent the development or arrest the progress of clinical atherosclerosis. Altschul and associates found that the concentration of serum cholesterol was reduced in normal and hypercholesterolemic individuals after ingestion of nicotinic acid Previously the same investigators had noted a similar effect in rabbits when nicotinic acid was administered orally or parenterally. Interest in these results led the authors to study the long-term effects of large daily doses of nicotinic acid in patients with hypercholesterolemia.

Patients were selected for study if the pretreatment concentration of plasma cholesterol was consistently higher than 250 mg per 100 cc. The nicotinic acid was initially administered in total daily doses of 3 gm. The schedule of medication was either one capsule (500 mg.) given six times daily or two capsules given three times daily. Treatment was continued at this dosage for at least four weeks. In patients in whom the concentration of plasma chloesterol decreased to and remained at levels less than 250 mg. per 100 cc., the daily dose was reduced to 1.5 gm. In others, in whom the concentration of cholesterol failed to decrease significantly, the daily dose was increased to 4.5 gm., and in two patients to 6 gm.

The plasma cholesterol level decreased significantly in 9 of 13 patients observed for 12 weeks and in 3 of 5 other patients observed for 4 weeks. The beta-alpha$_1$ ratio was reduced in 11 of 13 patients observed for 12 weeks and in 4 of 5 other patients observed for 4 weeks. The concentration of total lipids in the plasma was reduced in most of the patients but to a lesser degree than was the concentration of cholesterol. Side-reactions, consisting of flushing and pruritus, tended to diminish rapidly after the first few days of treatment. Urticaria, nausea, and vomiting, which were observed in a few patients, subsided when the drug was withheld temporarily and did not recur when administration was resumed.

Recurrent Pulmonary Hemorrhage with Hemosiderosis: So-Called Idiopathic Pulmonary Hemosiderosis. A. J. Bruwer, R. L. J. Kennedy and J. E. Edwards. Am. J. Roentgenol. 76:98-107 (July) 1956 [Springfield, Ill.].

To date, approximately 43 cases of a disease referred to as idiopathic pulmonary hemosiderosis have been described in the literature. The term "idiopathic pulmonary hemosiderosis" is unfortunate because it does not draw attention to the fact that it is the pulmonary hemorrhages that are idiopathic, whereas the cause of the hemosiderosis, that is, the bleeding, is known. The condition has been called "idiopathic pulmonary hemosiderosis" in order to distinguish it from the cardiac type of pulmonary hemosiderosis, which is usually attributable to mitral heart disease or chronic left ventricular failure. Other terms that have been used to describe idiopathic pulmonary hemosiderosis are essential brown induration of the lungs, hemolytic anemia with pulmonary hemosiderosis, essential pulmonary hemosiderosis, and Ceelin-Gellerstedt syndrome. The authors present the histories of three new patients with clinical symptoms consistent with those of patients having so-called idiopathic pulmonary hemosiderosis. The results of autopsy studies in two of these patients are presented.

The authors stress the fact that this is an entity with characteristic clinical, roentgenologic, and pathological features. The ratio of females to males in the reported cases is about 3:2. The patient's age at onset of the disease was 5 years or less in the majority of cases reported. The commonest manifestation is recurrent pulmonary hemorrhage leading to anemia and pulmonary hemosiderosis. Pulmonary fibrosis may also be present. The disease may be acute and the result fatal in a matter of months, or it may be insidious and of prolonged duration. The prognosis is usually poor, although recovery is not unkown. It is suggested that the underlying cause of the pulmonary hemorrhage may be a hypersensitivity.

Fibroelastosis in Adults: A Review of the Literature and Report of a Case. S. R. Guraieb and R. H. Rigdon. Am. Heart J. 52:138-148 (July) 1956 [St. Louis].

Fibroelastosis (fetal endocarditis, endocardial fibrosis, congenital idiopathic hypertrophy of the heart, and congenital fibroelastosis) is a recognized pathological entity in infants, but few cases have been observed in adults. Data on the 24 cases of fibroelastosis in adults (16 years of age or over) found in a survey of the American and British literature are reviewed. The presenting clinical manifestations were those of myocardial failure in almost all of these patients. The authors report on a 38-year-old man who in 1953 had a generalized skin eruption that was diagnosed as "leukemia cutis" by biopsy. The eruption subsided after irradiation, but it later recurred. In January, 1955, the patient was hospitalized with the same type of skin eruption. A biopsy at this time showed a lymphomatous infiltration of the dermis that was considered to be a "malignant lymphoma." There was a similar lymphomatous infiltration of the bone marrow that was considered to be leukemia. He was treated with irradiation, Purinethol, and cortisone. Anemia, severe leukopenia, and thrombocytopenia developed four months before his death in May, 1955. Pathological studies revealed that the cardiac lesions were identical with those observed in infants. It is believed that even in adults the process is congenital. The histological findings in support of this opinion are the absence of any inflammatory reaction and the presence of elastic tissue and a thin band of cardiac muscle in the thickened endocardium.

The Prevention of Thromboembolic Complications in Myocardial Infarction by Anticoagulant Therapy: A Clinical-Pathologic Study. H. I. Glueck, H. W. Ryder and P. Wasserman. Circulation 13:884-895 (June) 1956 [New York].

Autopsy records of 151 patients who died of myocardial infarction in a large private hospital were reviewed. Seventy-six patients received anticoagulant therapy, and 75 patients did not. Embolic phenomena were of common occurrence in patients dying of myocardial infarction. Clinically, these were often overlooked. The utilization of anticoagulant drugs reduced the incidence of embolic complications from 41% in the "untreated" series to 9% in the "adequately treated" group. The findings of the pathologist showed that the fatal emboli were reduced from 21% in the untreated group to 4% in the patients receiving adequate therapy. Inadequate, delayed, or poorly planned therapy afforded the patients no protection from this complication. Thrombophlebitis was markedly diminished in treated patients, and fewer mural thrombi were found in patients who received adequate therapy. Extension of the infarct or occurrence of a new infarct were not influenced by anticoagulant drugs.

Hemorrhage was not a significant cause of death in the present series. Rupture of the ventricle was noted to occur in both groups regardless of therapy. The patients could not be rigidly classified on admission to the hospital in regard to their eventual prognosis. This observation, plus the difficulty of diagnosis and the unpredictability of the disease, confirmed the inference that the decision to use anticoagulant therapy should not be dependent upon rigid diagnostic criteria for infarction. The benefit to be obtained from these drugs during the acute phase of illness can be ascribed to the prevention of thromboembolic complications. They are therefore indicated whenever thromboembolism is a threat.

The Mechanism of Cough Syncope. H. D. McIntosh, E. H. Estes and J. Warren. Am. Heart J. 52:70-82 (July) 1956 [St. Louis].

The syndrome of cough syncope until recently was considered a rare form of fainting. Earlier investigators suggested that it was an epileptic equivalent or the result of a laryngeal reflex. Later, these theories were abandoned and a circulatory mechanism producing cerebral anoxia was accepted as an explanation. Twenty patients who had experienced cough syncope were questioned in detail regarding these episodes. Studies were undertaken on 13 of these patients to determine the effect on the cardiorespiratory system of single and paroxysmal coughs. The intrathoracic pressure was measured by an air-filled esophageal balloon. The systemic arterial pressure and the cerebrospinal fluid pressure were measured through indwelling needles. These pressures were recorded simultaneously by a suitable Statham strain gauge or a Sanborn electromanometer on a Sanborn four-channel direct-writing oscillograph. In some studies the "net" pressure, i. e., the arterial pressure minus the intrathoracic or spinal fluid pressure, was recorded by a Statham differential strain gauge. For comparison, similar studies were made on a heterogenous group of 100 patients with no history of cough syncope.

These studies suggest that syncope due to cough is the result of the transmission of markedly elevated intrathoracic and intra-abdominal pressure to the cerebrospinal fluid compartment causing an essentially equal rise of the latter pressure. This increased cerebrospinal fluid pressure, by increasing the extravascular pressure around the cranial arteries and veins, causes blood to be "squeezed" from the cranium. Thus, the brain becomes rapidly "bloodless," anoxia develops, and syncope may occur. The occurrence of cough syncope apparently depends on many variables. The magnitude and duration of the cough paroxysm, which depend possibly on the body build and the compliance of the pulmonary system, seem of primary importance. The facility with which blood may be "squeezed" from the cranial vessels is also of importance and apparently depends on the dynamic distensibility of the vascular system not subjected to an increased extravascular pressure, the cardiac output, the total blood volume, and other, at present unknown, factors. The susceptibility of the cerebral cortex to anoxia will determine the duration of time that a "bloodless" brain must be maintained for syncope to occur. The results of this study are in agreement with other reports which suggest that cough syncope is a common form of fainting.

Cardiac Pain from Esophageal Lesions. G. Bourne. Lancet 1:892-893 (June 9) 1956 [London, England].

The first of the two patients presented was a 54-year-old man, who had a sudden attack of pain in the chest at the level of the upper part of the sternum, whence it radiated down the left arm and up into the neck. Later in the day he had another similar attack, and two days later he had several more. All were relieved by morphine. Although on his first admission the diagnosis was of coronary thrombosis, suspicion was aroused during the second admission by the normal electrocardiogram and by the normal size and shape of the heart. Because it had been noticed that from time to time he swallowed air, the esophagus became suspect, and on radiography a diverticulum of its middle third was found. The second patient, a 67-year-old man, had symptoms of angina of effort. The pain in the chest radiated to both sides, but not to the arms or to the neck. It was induced by hurrying and by climbing hills or stairs, and it was not associated with shortness of breath. It lasted two or three minutes. The electrocardiogram, after considerable exercise by the patient, remained normal in the standard leads. The esophagus showed a sliding hiatus hernia on roentgenography. These two histories are put on record to draw attention to the necessity for a full investigation of the esophagus when pain that clinically appears attributable to coronary disease is not associated with any other abnormality, whether clinical, electrocardiographic, or radiological. The esophageal condition should be treated by advice about the proper mastication of food, by a low-residue diet, by use of aluminum hydroxide or bismuth before meals and belladonna, and by having the head of the bed raised on 9-in. blocks. The complete disappearance of symptoms after such treatment would argue for an esophageal rather than a coronary origin.

An Evaluation of Twenty-Two Patients with Acute and Chronic Pulmonary Infection with Friedlander's Bacillus. B. M. Limson, M. J. Romansky and J. G. Shea. Ann. Int. Med. 44:1070-1081 (June) 1956 [Lancaster, Pa.].

The typical pulmonary lesion produced by Friedlander's bacillus (Klebsiella pneumoniae) is a fulminating lobar pneumonia noted for its high mortality rate. Before the use of antibiotics it was fatal in from 80 to 90% of those affected. The use of streptomycin, chlortetracycline, oxytetracycline, or chloramphenicol has altered its prognosis, but the disease still presents many difficulties in management. Respiratory infections caused by Friedlander's bacillus have been classified as follows: (1) acute Friedlander's pneumonias, (2) acute mixed infections or secondary infections, and (3) chronic respiratory infections. In the latter two, Friendlander's bacillus has been the predominant organism. Twenty-two patients have been observed during the last two years at the George Washington University and Georgetown University Divisions of the District of Columbia General Hospital; 13 had acute Friedlander's pneumonia and 9 had acute and chronic mixed pulmonary diseases. The patients, all but one of whom were males, ranged in age from 16 to 70, most of them being in the middle-aged group; 15 were alcoholics, and 5 of these were in delirium tremens on admission. Nine of the 13 patients with acute Friedlander's pneumonia died. Three of those who survived were only moderately ill. Two patients received tetracycline and recovered within a week. The third was severely ill and had delirium tremens on admission. He received penicillin initially; on the third day, when the diagnosis was established, the therapy was changed to administration of streptomycin and chlortetracycline, with very good results within a week. The fourth survivor, who had arrested apical pulmonary tuberculosis, became ill with lobar pneumonia five days before admission. He received erythromycin initially, but streptomycin and tetracycline were substituted on the third day. Later, treatment was with streptomycin and chloramphenicol, and he made a slow but complete recovery on this course of treatment. The nine patients who died were alcoholics, with four in delirium tremens, and all were severely ill. There were nine patients suffering from acute and chronic mixed pulmonary diseases, and only one of these died. Therapeutic failures in the treatment of severe infections are usually due to the virulence of the organism, the factor of lowered resistance, the lack of an agent effective against the micro-organism, or delay in therapy when an effective drug is available. This is especially true of Friedlander's pneumonia. The sulfonamides have been generally disappointing, and penicillin has not been effective. The mortality rate has been reduced since the introduction of streptomycin. Tetracycline and chloramphenicol have also been found effective, but the number of cases is too small to be the basis of an accurate statistical evaluation. Friedlander's pneumonia should be suspected in alcoholics showing evidence of severe pulmonary infection, and treatment directed against Friedlander's bacillus should be instituted without delay.

A Clinical Appraisal of Radioiodine Tests of Thyroid Function. W. M. McConahey, C. A. Owen Jr. and F. R. Keating Jr. J. Clin Endocrinol. 16:724-734 (June) 1956 [Springfield, Ill.].

Tracer doses of radioiodine were given to 208 patients in whom various thyroid disorders had been diagnosed and to 181 euthyroid patients who served as controls. Ninety-two of the 208 patients had toxic diffuse goiter, 46 had adenomatous goiter without hyperthyroidism, 19 had adenomatous goiter with hyperthyroidism, 13 had myxedema, and 38 were initially suspected of having toxic diffuse goiter but were later judged to be euthyroid. Seven diagnostic laboratory procedures employing radioiodine were evaluated in terms of their economy, the time required, and the ease of administration and operation, as well as diagnostic precision. These were (1) percentage of the tracer dose collected by the thyroid in six hours; (2) percentage of the tracer dose collected by the thyroid in 24 hours, (3) percentage of radioiodine excreted in the urine in 24 hours; (4) the proportional rate of accumulation of radioiodine by the thyroid, as described by Keating and associates; (5) the proportional rate of disappearance of the isotope from the blood into all organs other than the kidneys, as described by Keating and associates, (6) proportion of radioactivity in serum that is organically bound 24 hours after a tracer dose, i. e., the conversion ratio, as described by Clark and associates, and (7) volume of plasma cleared of inorganic iodide by the thyroid per minute, i. e., thyroidal iodide clearance, as described by Berson and associates. The most precise tests for the diagnosis of toxic diffuse goiter were the six-hour thyroidal-collection test, the thyroidal iodide clearance test, and the conversion ratio. The first test is the simplest and the most rapidly performed and requires the least radioactivity; consequently, it is best for the requirements of a routine radioiodine test. Only two tests, the 6-hour and the 24-hour thyroidal-collection test, were of value in the diagnosis of myxedema. None of the seven tests was decisive in determining whether a patient with a nodular goiter had or did not have hyperthyroidism.

Direct Measuring of the Portal Pressure. C. Arullani and L Gabrielli. Policlinico (sez. prat.) 63:690-694 (May 14) 1956 (In Italian) [Rome, Italy].

The authors studied a method of measuring directly the blood pressure of the portal vein. Aspiration of material for biopsy and measuring of the portal pressure can be performed at the same time with a needle 15 cm. long and 0.2 mm. thick. Vitamin K may be given three days before the measurement to assure coagulation of the blood. The needle is introduced at the level of the trunk of the portal vein. The vein has been penetrated when there is a full flow of blood through the needle into the syringe. The syringe is then disconnected, and the needle is connected with the manometer. Except for patients with hypertension, the blood comes from the portal vein if the pressure is above 6 cm. H_2O. The blood is certainly not from the portal vein if the pressure is below 3 cm. The authors tried the method in 14 normal persons. Values below 3 cm. H_2O were obtained twice, between 4 and 6 cm. twice, and between 7 and 11 cm 10 times. Fourteen patients with severe hepatitis and four with steatosis had pressure values between 6 and 12 cm. Twenty patients with mild hepatic sclerosis and with hypertension had pressure values between 9 and 18 cm.: average 14.3 cm. Seventeen patients with atrophic cirrhosis of the liver had pressure values between 21 and 40 cm.: average 29.5. Difficulty in locating the portal vein, possibility of puncturing an artery, and difficulty in distinguishing between portal blood and suprahepatic blood are among the limitations of the method.

Retroperitoneal Hemorrhage Simulating an Acute Abdominal Lesion During Dicumarol Therapy. M. D. Reiter. West Virginia M. J. 52:205-207 (July) 1956 [Charleston].

Reiter reports on three patients in whom acute abdominal symptoms developed in the course of treatment with bishydroxycoumarin (Dicumarol). There was a sudden onset of constant, nonradiating, nonrhythmic pain involving the flank, accompanied by ileus and followed by a fall in the number of circulating red blood cells and in the hemoglobin level. Two of the patients showed hypoactive peristalsis, muscle guarding, and leukocytosis; rebound tenderness was a prominent sign in the third. These are the classic signs and symptoms of retroperitoneal hemorrhage. The first two patients later showed ecchymosis, a symptom that lent further weight to the diagnosis. The recognition of retroperitoneal hemorrhage during Dicumarol therapy is important, especially when the primary disease is a recent myocardial infarction and unnecessary surgery must be avoided.

Some disturbing factors in these patients were the absence of cutaneous or urinary bleeding and a prothrombin time that, while not normal, was not strikingly abnormal. The diagnosis could not be proved by histological section, since the patients came to neither surgery nor autopsy. The author emphasizes that, so long as Dicumarol therapy remains popular in the treatment of myocardial infarction, retroperitoneal hemorrhage may develop in other patients, the more so since hemorrhage from hypoprothrombinemia has no predilection for a special portion of the body and since Dicumarol intoxication is admittedly common.

Treatment of Diabetics with BZ-55. S. Di Lorenzo and A. Miola. Riforma med. 70:619-623 (June 2) 1956 (In Italian) [Naples, Italy].

Twenty-two diabetics were treated with BZ-55. Dosage was 2.5 gm. the first day, 1.5 gm. for the next 10 days, and 1 or 0.5 gm., depending on the patient, for the remaining days of treatment. Return to normal glycemia was noticed after 48 hours in some patients and after 6 to 10 days in others. BZ-55 was given after meals. There were no side-effects. Patients were from 42 to 72 years of age. Only four were below 45 years old. Insulin was withdrawn in 12 patients and satisfactorily replaced with BZ-55. The drug had no effect on the weight of the patients. Very good results were noticed in patients with mild disease. In only one patient was BZ-55 unable to replace insulin. The drug had no effect in a woman with a severe form of diabetes. The treatment lowered the blood sugar level and the diabetic hyperlipemia.

Viral Hepatitis: Descriptive Epidemiology Based on Morbidity and Mortality Statistics. I. L. Sherman and H. F. Eichenwald. Ann. Int. Med. 44:1049-1069 (June) 1956 [Lancaster, Pa.].

Viral hepatitis is one of the most important communicable diseases in the United States. Two separate entities are included under this term: infectious hepatitis and serum hepatitis. They are each produced by distinctly different infectious agents. The history, prior to 1952, of viral hepatitis, which is now included under the heading of infectious hepatitis in the national morbidity statistics, is obscure. Records for deaths attributable to infectious hepatitis are available since 1949 in the latest revision of the International Lists of Diseases and Causes of Death; deaths ascribed to serum hepatitis are included in the broad category of deaths due to accidents, poisoning, and violence. Within this category they are contained in two general classifications: those due to postimmunization jaundice and hepatitis and those due to therapeutic misadventure in infusion or transfusion. During World War II the disease was a major problem among the Armed Forces. Outbreaks of serum hepatitis were associated with the use of certain lots of yellow fever vaccine containing human blood serum as a buffer. It is known to be a much more severe disease than infectious hepatitis, with an appreciable death risk. The number of reported cases of viral hepatitis, comprising infectious and serum hepatitis, has increased during the four years of the present study, with the peak incidence occurring in the late winter or early spring months in all regions of the United States. The seasonal low has consistently occurred during the summer, and this has also been observed in the Scandinavian countries and in England. This cyclic behavior emphasizes the epidemic nature of infectious hepatitis; seasonal distribution of the recorded deaths in the United States, however, shows little variation during the year, suggesting that deaths may be due mainly to serum hepatitis. A geographic classification of reported case data by state and region of the United States by year suggests that there has been an actual increase in the incidence of the disease, along with improvement in the reporting of cases. Such data as have been obtained on incidence by age and sex indicate that the highest incidence occurs in persons under 15 years and that both sexes are equally susceptible to the disease. The recorded death data show increasingly higher rates with increasing age, indicating that hepatitis is more severe in older age groups or that the incidence of serum hepatitis increases in these age groups. There is an excess of deaths in females in the age groups between menarche and menopause and an excess of deaths in males in the age groups over 50 years. The reasons for these differences are not apparent.

Blood Sugar Lowering Sulfonamide Derivatives. G. R. Constam, D. Bonhôte, H. Fellmann and others. Schweiz. med. Wchnschr. 86:699-705 (June 16) 1956 (In German) [Basel, Switzerland].

Since November, 1955, carbutamide (Nadisan), a sulfonamide derivative, has been given orally to 60 women and 40 men with diabetes mellitus who were either treated ambulatorily at the Medical University Policlinic in Zurich or hospitalized in the Waid City Hospital in Zurich, Switzerland. Seventy of the 100 patients showed a good response to carbutamide; the remaining 30 responded unsatisfactorily or were therapeutic failures. The pancreas is possibly the point of attack by the sulfonamide derivative, which produces a drop in the blood sugar level. The mode and mechanism of action have not been elucidated. Blocking of the adrenals and of the glucagon present in the circulation can be definitely excluded. An inhibitory action exerted on the anterior pituitary does not seem likely. The effect of carbutamide may depend on the presence of endogenous insulin.

Carbutamide, designated BZ-55 by the German investigators, is suitable for the treatment of diabetes mellitus of less than five years' duration in sthenic patients over 45 years of age. The use of the drug is contraindicated in children, adolescents, and patients of asthenic type in whom the disease began before they reached the age of 45; in patients with acute complications, with precomatose or comatose conditions; in those with severe renal impairment; and in those with mild diabetes mellitus, who may obtain compensation with diet and exercises alone. Carbutamide may be given a trial in other patients with diabetes mellitus, and it is even indicated in patients of advanced age who are relatively resistant to insulin. The side-effects of carbutamide are mild and rare, but the occurrence of severe, fatal hypoglycemia and of uremia is possible. Consequently, carbutamide therapy should not be started without daily control of the blood sugar level. A change from insulin to carbutamide therapy requires hospitalization of patients who have previously been treated with insulin. Diet remains the basis for successful treatment with carbutamide. A diet poor in fats and relatively rich in carbohydrates (160 to 200 gm.) seems to provide favorable conditions for treatment with carbutamide. The possibility of late damage caused by carbutamide or gradual or sudden failure of the drug cannot be definitely excluded, since the patients have not yet been followed up for a sufficiently long period.

Steroid Therapy of Hypercalcemia and Renal Insufficiency in Sarcoidosis. R. W. Phillips and D. P. Fitzpatrick. New England J. Med. 254:1216-1222 (June 28) 1956 [Boston].

The authors report the successful treatment by steroid therapy of hypercalcemia in two patients with sarcoidosis and point out subsequent improvement in renal function. The first patient, a 28-year-old man, was given 100 mg. of cortisone daily for 14 days. The serum calcium level promptly fell to normal within five days, skin lesions disappeared, the appetite returned, and the patient became asymptomatic. Hypercalcemia did not recur during the two and a half years of follow-up study, although there was no further steroid medication. Renal insufficiency was present before treatment during the period of uncontrolled hypercalcemia. Improvement in renal function following cortisone therapy was minimal after three months, but at the end of two and a half years reversal of renal insufficiency had occurred, with return to nearly normal function. The second patient, a 48-year-old man, received 30 mg. of prednisone (Meticorten) daily for nine days and then 40 mg. daily for five days. The treatment failed to influence the elevated serum calcium level or the results of the urinary Sulkowitch test. Cortisone therapy (300 mg. daily for 11 days) was followed by a prompt fall of the abnormally high serum calcium levels to normal. Hypercalcemia did not recur during the 74 days of follow-up study, although there was no further steroid medication. This is admittedly not a prolonged period of observation; nevertheless, no immediate "rebound" occurred in the serum calcium level when cortisone was omitted. Renal function showed significant improvement within 45 days and had returned to nearly normal in 74 days.

The authors review data from other sources on correction of hypercalcemia in sarcoidosis with cortisone or corticotropin (ACTH) and call attention to the apparently uniform success. Maintenance steroid therapy does not appear routinely indicated, since relapse to abnormally high calcium levels does not necessarily occur. The amount of improvement in renal function with successful treatment of the hypercalcemic state was inversely proportional to the degree of renal impairment present. Little benefit was obtained in patients with advanced azotemia. Investigation of the status of calcium metabolism should be a routine procedure in all patients with sarcoidosis. If hypercalcemia is found, treatment with cortisone or corticotropin should be instituted. It is only by early use of these measures that renal insufficiency secondary to nephrocalcinosis can be prevented.

Pelger Anomaly: Pelger-Huet's Anomaly. E. Ó. Jóhannsson Ugesk. læger 118:583-588 (May 31) 1956 (In Danish) [Copenhagen, Denmark].

Pelger-Huet's anomaly is a familial anomaly with dominant inheritance and is independent of sex. It is known only by the blood picture. The typical changes in the blood picture make the anomaly easily recognizable, once it has been met with. The finding of the same blood picture in parents or children confirms the diagnosis. The hematological changes are characterized by inhibition of segmentation of the nuclei of both neutrophil and eosinophil granulocytes. There are about the same number of segmented and unsegmented nuclei among the neutrophil granulocytes. Most of the segmented nuclei have two segments, and only isolated nuclei have more segments. In Denmark and several other countries the anomaly was not described until recently, but it has long been well known in a number of countries. Cases in which the anomaly could not be established in the parents but was seen in the children are explained as recurrence of the gene by mutation. A case of Pelger's nuclear anomaly is reported in a patient in whom malignant lymphogranulomatosis was suspected. The anomaly was found in 5 of 13 members of the family, all of whom, except the patient, are well. There were no "Teiltrager" (partial carriers).

The Treatment of Barbiturate Poisoning With or Without Analeptics. J. E. Eckenhoff and W. Dam. Am. J. Med. 20:912-918 (June) 1956 [New York].

Data accumulated at the Copenhagen Narcotic Center show that supportive therapy alone is the method of choice in treating barbiturate poisoning. Mortality is strikingly low, and use of metrazol, picrotoxin, and other analeptics does not increase the survival rate and may even increase the death rate. Convulsions, vomiting with aspiration of gastric contents, and cardiac arrhythmias can be anticipated after the use of stimulant drugs. Analeptics may cause irreparable brain damage during anoxia by increasing cerebral oxygen demand in excess of available oxygen supply. The principles of supportive therapy are outlined, with emphasis on the importance of maintaining a patent airway. Comparison of treatment in two series of poisoned patients is difficult because of lack of standardization of basic treatment and inadequacy of criteria for classification of the severity of poisoning. A new method of treatment, hemodialysis, seems particularly promising, although sufficient data on its use have not appeared. The general problem is similar to that of treating a postanesthetic comatose patient, and it is suggested that a physician-anesthetist participate in the treatment of all cases of narcotic poisoning.

Sulfhemoglobinemia with Report of Case. E. Harsløf. Ugesk læger 117:551-553 (May 24) 1956 (In Danish) [Copenhagen, Denmark].

Severe sulfhemoglobinemia occurred in a patient who had been taking magnesium sulfate for 25 years. Since there had been no intake of substances forming methemoglobin, believed by most authors to be necessary for the formation of sulfhemoglobin, and since it is unlikely that magnesium sulfate alone can cause sulfhemoglobin, the case is presumably to be included under the so-called enterogenic cyanosis. In this condition, several cases of which have been reported, sulfhemoglobin is believed to be formed as the result of an intestinal disorder that causes the production of methemoglobin-forming substances in connection with hydrogen sulfide. The patient, who also had moderate anemia, together with reticulocytosis pointing to accelerated hematopoiesis, recovered after the magnesium sulfate was withdrawn and the intestinal function was regulated. Sulfhemoglobin is eliminated slowly, in the course of three or four months, in accordance with the normal breaking down of the erythrocytes, whereas methemoglobin disappears in a few hours or days.

Salt Loss in Chronic Renal Disease. A. E. Read. Brit. M. J 1:1399-1401 (June 16) 1956 [London, England].

Read reports on two patients with the "salt-losing syndrome." The syndrome in one of these patients was complicated by the appearance of a flaccid paralysis due to hyperkalemia. This responded dramatically to the intravenous administration of sodium chloride. The second patient was a woman aged 70, and in this patient the syndrome was accompanied by marked nitrogen retention. Despite this, the response to therapy with salt was most gratifying. The peripheral circulatory failure usually associated with severe sodium deficiency was absent in this case. Read stresses the importance of a thorough investigation of patients with "uremia." Analysis of blood and urine may reveal the presence of sodium depletion associated with excessive renal loss. The treatment of this aspect of the underlying renal condition is occasionally a life-saving measure. The ultimate prognosis depends on the severity of the primary lesion, usually a chronic pyelonephritis, but the salt-losing phase of the disease is very simply treated and may rescue the patient from what may appear to be a terminal phase of chronic renal failure.

SURGERY

Recent Ideas in Gastric Surgery. T. H. Somervell. J. Internat Coll. Surgeons 25:713-717 (June) 1956 [Chicago].

As a result of his experience with 6,000 patients operated on for duodenal ulcer, the author emphasizes the fact that the secretion of acid in a resting stomach or in response to a nervous stimulus, such as hunger, is to be considered entirely separately from the secretion of acid during the digestive period, which is not dependent on the vagi and is dependent on the hormone secreted by the pyloric antral mucosa. Consequently, the indiscriminate performance of vagotomy with gastrojejunostomy or some form of gastrectomy with a good free anastomosis in all cases of duodenal ulcer is to be deprecated. Highly acid fasting juice demands vagotomy. High acidity of the gastric juice in the course of the digestive period may be treated adequately by removal of the pyloric half of the stomach only. High acidity of the gastric juice throughout, i. e., in the resting phase and in the digestive phase, demands both vagotomy and hemigastrectomy Since recurrences of ulcer after resection depend on the presence of intact vagi, and since recurrences after vagotomy depend on the presence of the antrum, the combination of gastric hemiresection with vagotomy must be reckoned as the standard operation for duodenal ulcer in patients with hyperacidity.

Coarctation of the Aorta Associated with Patent Ductus Arteriosus. J. C. Cooley, J. W. Kirklin, O. T. Clagett and others. Circulation 13:843-849 (June) 1956 [New York].

The records of 193 patients in whom coarctation of the aorta was treated surgically at the Mayo Clinic were reviewed. In 14 instances (7.3%) the ductus arteriosus was grossly patent. Since the combination of patent ductus arteriosus and coarctation of the aorta poses special anatomic, physiological, and surgical problems, observations on these 14 patients are discussed. The results of operation in the group of eight patients having a patent ductus arteriosus associated with coarctation of the aorta and no pulmonary hypertension were good in every case except for one postoperative death. Of the six patients having pulmonary hypertension, patent ductus, and coarctation of the aorta, two died in the postoperative period. Of the four patients surviving operation, three obtained good results, with adequate lowering of the systemic blood pressure. One patient, in whom the ductus was divided without repair of the coarctation, obtained only a fair result.

The authors emphasize the fact that it is important to recognize before operation those patients in whom a patent ductus arteriosus is associated with pulmonary hypertension. In those with severe pulmonary hypertension and attachment of the ductus in the region of the coarctation or distal to it, considerable amounts of the blood going into the descending aorta may be coming from the pulmonary artery. The collateral circulation is sometimes poorly developed under these circumstances. Then cross-clamping of the aorta for a period long enough to allow an aortic resection and anastomosis might cause paralysis of the lower limbs. This catastrophe did not occur in any of the patients in this series. The anastomosis should, however, be made as quickly as possible. Moderate hypothermia was utilized in one case. The fact should be considered in the postoperative management of these patients that high oxygen concentrations lower the pulmonary artery pressure in most persons with pulmonary hypertension associated with congenital heart disease. For this reason, the patient is kept under high oxygen concentrations for a prolonged period after operation, in some instances from 7 to 10 days. Though this maneuver is on an empiric basis, it may lower the pulmonary artery pressure enough to take some of the strain off the right ventricle during the critical period.

The Hemodynamic Results of Surgical Correction of Atrial Septal Defects: A Report of Thirty-Three Cases. J. W. Kirklin, W. H. Weidman, J. T. Burroughs and others. Circulation 13: 825-833 (June) 1956 [New York].

Kirklin and associates describe the results of operation in the first 33 of a total of 59 patients with atrial septal defect and left-to-right shunt, who were treated at the Mayo Clinic before Dec. 1, 1955. All 33 patients had atrial septal defects with left-to-right shunting of blood across the defect; many had additional complicating features. Some had a degree of right-to-left shunting, as well. Only four patients were entirely asymptomatic. Thirty-one of the 33 patients were operated on with the atrial-well technique of Gross and associates, with minor changes in details of suturing. A suitable piece of noncompressed Ivalon sponge was used to close the defects. The technique was modified for the patients with associated and complicated defect. Hemodynamic data were obtained before, during, and after the operation. The results of operative closure of atrial septal defects were excellent in 27 cases, fair in 4, and poor in one. There was one postoperative death. On the basis of these results, it seems justified to advise repair of atrial septal defects in all patients with significant physiological derangement resulting from this anatomic malformation. In the subsequent 26 cases, bringing the entire series to 59 cases, closures have all been judged to be complete.

Gross Damage to the Portal Vein and Hepatic Artery During Cholecystectomy. N. R. Wyndham. Australian & New Zealand J. Surg. 25:292-295 (May) 1956 [Melbourne, Australia].

Division of the portal vein with delayed repair occurred in a 34-year-old woman who was subjected to a cholecystectomy. After the operation an increasingly large amount of blood came from the drainage tube. By the next day it was obvious that intraperitoneal bleeding had also occurred. For six days after the operation her condition became gradually worse, although the pulse rate and temperature did not vary significantly. On the seventh day her deterioration became more obvious. Her complexion was sallow, with some icterus. Bile and albumen appeared in the urine. On the 11th day, operation was undertaken as a desperate measure because of a sudden deterioration in her condition. A large quantity of old blood was evacuated, about half consisting of clots. The common bile duct and the hepatic artery were intact, but the portal vein had been completely divided. The hepatic end had been ligated, but the distal end was occluded by a clot. This was friable and was removed with a probe and sucker to a distance of 2.5 in. (6.25 cm.). Only a small trickle of blood resulted. The hepatic end of the vein was cleared in a similar manner and the continuity restored with fine silk sutures. Two years after the operation, the patient was well and free of all symptoms referable to the biliary tract.

Ligation of the common hepatic artery has frequently been performed for portal hypertention as a deliberate procedure. The only liver disease in the case reported here was due to a chronic biliary obstruction. The patient was a 49-year-old woman in whom a stricture of the common hepatic duct was found at operation. This was excised and repaired over a T-tube, the long limb of which was introduced through an opening below the stricture. A somewhat abnormal relation of the structures around the common bile duct was seen, the portal vein lying anterior and the common hepatic artery being anterior to the common bile duct. The immediate postoperative course was normal. On the 20th postoperative day the patient complained of epigastric pain and vomited a few ounces of blood-stained fluid. A diagnosis of intra-abdominal bleeding was made. At operation (one month after the first one) it was found that the bleeding came from a large hole in the side of the hepatic artery, which had been eroded by the T-tube. Complete obliteration of the artery with slik sutures was required. The results of ligation of the hepatic artery were awaited with some trepidation. The semicomatose, intensely jaundiced appearance of the patient was thought to be due to acute liver failure. Recovery was much more rapid than expected. In what way compensation for the loss of blood supply from the hepatic artery occurred is not clear. Apparently, numerous small vessels had penetrated the liver substance from the surrounding connective tissue. New systemic vessels were obvious at the last operation (required because of stricture of the duct), but these could have played little part in the immediate recovery phase. There has been no demonstrable damage to the liver due to the ligation of the hepatic artery in this case.

Aspects of Bronchial Adenoma. F. Holle and R. Schautz. Arch. klin. Chir. 281:583-597 (No. 6) 1956 (In German) [Berlin, Germany].

The authors discovered 7 bronchial adenomas among 100 pulmonary tumors. The bronchial adenoma stands in fifth place, when the solitary pulmonary foci are classified according to frequency. Tuberculomas, bronchial carcinomas, hamartomas, and malignant metastases are more frequent. Bronchial adenoma usually begins at a relatively early age, but its growth is slow. The tumor is extremely vascular and usually has its origin in the larger bronchi. Although the central and perihilar sections of the bronchial tree are the main areas of localization, adenomas may also occur extrabronchially and in the peripheral sections of the lung. They grow either in the form of a pedicled, cylindrical polyp extending into the bronchial lumen or within the bronchial wall growing through it toward the lumen and outward. The pedicled endobronchial polyps lead to gradual obstruction of the bronchus, which is intermittent at first and later becomes permanent. The mural adenomas, which grow through and beyond the wall, destroy the bronchial wall and the cartilages, but they remain separated from the mucosa and alveolar parenchyma by a layer of capsular connective tissue. Patients with bronchial adenoma usually have a long history of illness. Five of the authors' seven patients had had symptoms for more than seven years.

Pleuropulmonary suppurations that recur for years and finally produce a pleural empyema are the most characteristic clinical manifestation of a bronchial adenoma. Coughing, asthma-like during the two and a half years of follow-up study, although there was no further steroid medication. Renal insufficiency was present before treatment during the period of uncontrolled hypercalcemia. Improvement in renal function following cortisone therapy was minimal after three months, but at the end of two and a half years reversal of renal insufficiency had occurred, with return to nearly normal function. The second patient, a 48-year-old man, received 30 mg. of prednisone (Meticorten) daily for nine days and then 40 mg. daily for five days. The treatment failed to influence the elevated serum calcium level or the results of the urinary Sulkowitch test. Cortisone therapy (300 mg. daily for 11 days) was followed by a prompt fall of the abnormally high serum calcium levels to normal. Hypercalcemia did not recur during the 74 days of follow-up study, although there was no further steroid medication. This is admittedly not a prolonged period of observation; nevertheless, no immediate "rebound" occurred in the serum calcium level when cortisone was omitted. Renal function showed significant improvement within 45 days and had returned to nearly normal in 74 days.

The authors review data from other sources on correction of hypercalcemia in sarcoidosis with cortisone or corticotropin (ACTH) and call attention to the apparently uniform success. Maintenance steroid therapy does not appear routinely indicated, since relapse to abnormally high calcium levels does not necessarily occur. The amount of improvement in renal function with successful treatment of the hypercalcemic state was inversely proportional to the degree of renal impairment present. Little benefit was obtained in patients with advanced azotemia. Investigation of the status of calcium metabolism should be a routine procedure in all patients with sarcoidosis. If hypercalcemia is found, treatment with cortisone or corticotropin should be instituted. It is only by early use of these measures that renal insufficiency secondary to nephrocalcinosis can be prevented.

Pelger Anomaly: Pelger-Huet's Anomaly. E. Ó. Jóhannsson. Ugesk. Læger 118:583-588 (May 31) 1956 (In Danish) [Copenhagen, Denmark].

Pelger-Huet's anomaly is a familial anomaly with dominant inheritance and is independent of sex. It is known only by the blood picture. The typical changes in the blood picture make the anomaly easily recognizable, once it has been met with. The finding of the same blood picture in parents or children confirms the diagnosis. The hematological changes are characterized by inhibition of segmentation of the nuclei of both neutrophil and eosinophil granulocytes. There are about the same number of segmented and unsegmented nuclei among the neutrophil granulocytes. Most of the segmented nuclei have two segments, and only isolated nuclei have more segments. The general problem is similar to that of treating a postanesthetic comatose patient, and it is suggested that a physician-anesthetist participate in the treatment of all cases of narcotic poisoning.

Sulfhemoglobinemia with Report of Case. E. Harsløf. Ugesk læger 117:551-553 (May 24) 1956 (In Danish) [Copenhagen, Denmark].

Severe sulfhemoglobinemia occurred in a patient who had been taking magnesium sulfate for 25 years. Since there had been no intake of substances forming methemoglobin, believed by most authors to be necessary for the formation of sulfhemoglobin, and since it is unlikely that magnesium sulfate alone can cause sulfhemoglobin, the case is presumably to be included under the so-called enterogenic cyanosis. In this condition, several cases of which have been reported, sulfhemoglobin is believed to be formed as the result of an intestinal disorder that causes the production of methemoglobin-forming substances in connection with hydrogen sulfide. The patient, who also had moderate anemia, together with reticulocytosis pointing to accelerated hematopoiesis, recovered after the magnesium sulfate was withdrawn and the intestinal function was regulated. Sulfhemoglobin is eliminated slowly, in the course of three or four months, in accordance with the normal breaking down of the erythrocytes, whereas methemoglobin disappears in a few hours or days.

Salt Loss in Chronic Renal Disease. A. E. Read. Brit. M. J. 1:1399-1401 (June 16) 1956 [London, England].

Read reports on two patients with the "salt-losing syndrome." The syndrome in one of these patients was complicated by the appearance of a flaccid paralysis due to hyperkalemia. This responded dramatically to the intravenous administration of sodium chloride. The second patient was a woman aged 70, and in this patient the syndrome was accompanied by marked nitrogen retention. Despite this, the response to therapy with salt was most gratifying. The peripheral circulatory failure usually associated with severe sodium deficiency was absent in this case. Read stresses the importance of a thorough investigation of patients with "uremia." Analysis of blood and urine may reveal the presence of sodium depletion associated with excessive renal loss. The treatment of this aspect of the underlying renal condition is occasionally a life-saving measure. The ultimate prognosis depends on the severity of the primary lesion, usually a chronic pyelonephritis, but the salt-losing phase of the disease is very simply treated and may rescue the patient from what may appear to be a terminal phase of chronic renal failure.

SURGERY

Recent Ideas in Gastric Surgery. T. H. Somervell. J. Internat Coll. Surgeons 25:713-717 (June) 1956 [Chicago].

As a result of his experience with 6,000 patients operated on for duodenal ulcer, the author emphasizes the fact that the secretion of acid in a resting stomach or in response to a nervous stimulus, such as hunger, is to be considered entirely separately from the secretion of acid during the digestive period, which is not dependent on the vagi and is dependent on the hormone secreted by the pyloric antral mucosa. Consequently, the indiscriminate performance of vagotomy with gastrojejunostomy or some form of gastrectomy with a good free anastomosis in all cases of duodenal ulcer is to be deprecated. Highly acid fasting juice demands vagotomy. High acidity of the gastric juice in the course of the digestive period may be treated adequately by removal of the pyloric half of the stomach only. High acidity of the gastric juice throughout, i. e., in the resting phase and in the digestive phase, demands both vagotomy and hemigastrectomy. Since recurrences of ulcer after resection depend on the presence of intact vagi, and since recurrences after vagotomy depend on the presence of the antrum, the combination of gastric hemiresection with vagotomy must be reckoned as the standard operation for duodenal ulcer in patients with hyperacidity.

survivors have been followed for from 3 to 43 months. Substitution medicaments included, besides insulin, thyroxin, adrenocortical hormone, and also in some cases androgenic and estrogenic hormone. The blood pressure and the heart volume decreased. The glomerular filtration rate was lessened, while the renal plasma flow remained unchanged. The albuminuria was reduced. The vascular calcifications present before the operation were not affected, but new calcifications were not demonstrable after the operation. The material does not allow conclusions as to possible improvement in the renal condition. In some cases the visual capacity improved. Progress of the diabetic retinopathy was demonstrable in only one instance. The results so far are encouraging.

NEUROLOGY & PSYCHIATRY

Electroencephalography in Cerebral Apoplexy. B. Harvard and E. Skinhøj. Nord. med. 55:679-681 (May 17) 1956 (In Danish) [Stockholm, Sweden].

In the neurological department of Frederiksberg Hospital, routine electroencephalographic examination was carried out during the last two or three years in practically all patients with cerebral apoplexy as soon as the clinical condition allowed. Of the 147 patients examined, 14 showed certain signs of cerebral hemorrhage. In 54, cerebral thrombosis was probable, in 7, with heart disease complicated with perpetual arrhythmia, embolic apoplexy was likely; in 24, apoplexy was regarded as a crisis in an already present encephalopathy, arteriosclerotic or hypertensive; and in 48 differential diagnosis was not possible. In the main, no encephalographic picture was found to be specific for cerebral apoplexy; the focal and diffuse abnormalities resembled those found in other forms of brain disorder. The rare occurrence of spike activity is thought to indicate that the lesions are most often subcortical. There was a close connection between the electroencephalographic findings and the clinical condition and also the psychic condition after the acute insult was past.

Thirty-two of the 38 patients with marked delta focus and only 15 of the 53 with normal electroencephalograms were gravely affected psychically. The paralyses showed good remission in 6 of the patients with marked delta focus and in 33 of those with normal electroencephalogram. Patients with hemorrhages usually have severe focal abnormalities, as do those with embolism, while patients with thrombosis present only slight focal abnormalities or fully normal records. Electroencephalography can afford considerable help in the differential diagnosis between the different forms of apoplexy, but it is stressed that the examination of these patients, who are often exhausted, presents technical difficulties and a probably not negligible trauma for the patients. The examination is especially indicated for the patients for whom anticoagulant therapy is most desirable, i. e., patients whose prognosis for life is good but who, because of the extent of the paralyses, will be forced to lead a sedentary life for a long time. Here the attempt should be made before the start of anticoagulant therapy to make sure that there is no intracranial hemorrhage.

Cardiopathies, Electroshock, and Succinylcholine. M. Porot and E. Bisquerra. Presse méd. 64:1101 (June 16) 1956 (In French) [Paris, France].

Eleven psychiatric patients affected by more severe cardiopathies than those related to neurovegetative disorders or to hypertension without heart decompensation were treated by electroshock and did not suffer cardiac complications from it. Most of these patients, affected with valvular, permanently arrhythmic, or coronary heart disease, were treated by cardiotonics and vascodilators during electroshock. After light anesthesia and before electroshock, seven of them were given from 60 to 100 mg. of iodide of succinylcholine (celocurine), a curarizing preparation. These patients thus had the advantages of no preliminary spasm, considerable diminution of histamine liberation, only brief anoxia (as a result of artificial oxygenation), and, most important, great reduction of the muscular effort, that is the motor crisis of electroshock without curarization. Less aggressive psychiatric therapeutics should be tried on cardiac patients before electroshock. However, each case must be studied individually to see if the continued acute mental condition and psychiatric risk (especially suicide) that may be caused by not using electroshock are more serious than the risk of cardiac complications subsequent to electroshock. Since the latter risk is notably reduced by the use of the method of anesthesia and curarization with succinylcholine, cardiac contraindications for electroshock have become the exception.

Electroencephalography in Unilateral Subdural Hematoma in Adults. A. Lundervold and R. Nordlie. Nord. med. 55:681-686 (May 17) 1956 (In Norwegian) [Stockholm, Sweden].

The most typical electroencephalographic findings in chronic subdural hematoma is a focal reduction of voltage in the normal activity together with a maximum of slow waves over the hematoma. Less often the electroencephalogram can either show a reduction of the voltage or only focal slow waves. In exceptional cases, the maximum of pathological activity will be on the contralateral side, but in these cases the bilaterally synchronous waves are reduced over the hematoma, and correct focal diagnosis can also be made in these more difficult cases. Although the electroencephalogram is relatively typical in subdural hematoma, the findings are by no means pathognomic; other intracranial disorders can at times show a similar picture. The examination can, however, be of decisive significance both in diagnosis and perhaps particularly for localization of the pathological process in cases in which a subdural hematoma is suspected. For this reason and because the examination is painless, routine electroencephalography is carried out in the Rikshospital in all patients with suspected hematoma. Postoperative examination is made to determine whether the pathological activity persists. This is important in prognosis, perhaps especially so in the cases in which the clinical examination shows normal conditions. Electroencephalography can play an important part in connection with the clinical findings and possibly those of other supplementary examinations. Cooperation between the neurosurgical and the neurophysical departments is important.

GYNECOLOGY & OBSTETRICS

Anesthesia for Cesarean Sections at the University Women's Clinic in Jena. E. Rimbach. München. med. Wchnschr. 98:816-819 (June 8) 1956 (In German) [Munich, Germany].

The author describes experiences with anesthetic methods in 100 women subjected to abdominal cesarean section. In 50 of these peridural anesthesia was used and in the other 50 general anesthesia was employed (in 43 ethyl chloride anesthesia was used, and in 7 anesthesia was begun with hexobarbital [Evipal]). The peridural anesthesia caused no complications in either the mothers or the infants. General anesthesia was followed by asphyxia in a considerable number of infants. Four infants died within a few hours after delivery, most likely as the result of the general anesthesia; three of these four fatalities involved prematurely born infants. The author believes that general anesthesia is too dangerous in premature deliveries. It should be replaced by peridural anesthesia, which is induced by means of 50 mg. of tetracaine hydrochloride (Medicain).

Embolism by Amniotic Fluid. R. Garneau, J. Francoeur and F. Shooner, Laval méd. 21:793-808 (June) 1956 (In French) [Quebec, Canada].

The authors report a fatal pulmonary embolism by amniotic fluid in a 41-year-old multigravida. Her clinical symptomatology pointed to this hypothesis, confirmed five hours later by an autopsy. Noteworthy points are the highly pathological obstetric history of the patient (five miscarriages) and the dramatic character of the termination of her fifth pregnancy. This miscarriage was accompanied by abundant hemorrhage with slow formation of the coagulum, by mydriasis, and by vomiting, which might have indicated an attenuated form of amniotic fluid embolism. The sixth pregnancy was terminated at eight and one-half months, when the patient died suddenly of an amniotic fluid embolism in spite of endotrachael intubation and cardiac massage. At autopsy, a great quantity of small whitish clots (squamous debris and sealed-off pavement cells) were found in the blackish-red and uncoagulated blood of the pulmonary artery and in the right side of the heart. They were identified as debris of the amniotic liquid. Histological examination of the lungs revealed areas of atelectasis with *acidophilic serous effusion* and dust cells *in* some alveoli. In all the sections, a great number of arterioles and interalveolar capillaries contained granular debris and some lanugo. Some of these vessels were literally obliterated by masses of scales. These findings established the diagnosis of pulmonary embolism by amniotic fluid.

Intrafollicular Ovarian Pregnancy. M. L. Bobrow and L. B. Winkelstein. Am. J. Surg. 91:991-998 (June) 1956 [New York].

The case reported is the first proved instance of a primary intrafollicular ovarian pregnancy occurring at the Harlem Hospital among 587 patients operated on for ruptured ectopic pregnancy during the year 1943 to 1953. The patient was a 36-year-old Negro woman who had had three previous deliveries. A diagnosis of a ruptured ectopic gestation was made on the basis of the physical findings. Approximately 1,000 cc. of old and fresh fluid blood, together with large blood clots, was seen when the peritoneal cavity was opened. Exploration of the pelvis revealed a large mass, 20 by 15 cm., that was suspended from the uterus by the ligament of the ovary. The left tube and the ovarian mass were removed. The postoperative course was uneventful. Anemia resulting from loss of blood was corrected by transfusion. The extirpated specimen consisted of a soft cystic mass, measuring 12 by 6 by 7 cm., presenting on one surface a fallopian tube bound down by dense adhesions but anatomically separated from the cystic mass. Sectioning of the gross specimen revealed several cystic cavities, one of which was lined by a smooth shiny membrane, on its floor there was a large mass that appeared to be the maternal surface of a placenta. Further examination revealed amniotic fluid and a placenta with its membranes and cord that was attached to a fetus measuring 10 cm. from crown to rump. Microscopic examination showed infiltration of the corpus luteum by trophoblastic elements of the placenta from within the cavity of the corpus luteum itself. Examination of the cornual end of the tube showed the lumen to be obliterated as the result of chronic salpingitis. The final diagnosis was intrafollicular ovarian pregnancy and chronic salpingitis.

A review of the literature revealed 154 cases of true primary ovarian pregnancies. The final diagnosis of intrafollicular pregnancy rests with the operative and pathological findings. The causation of ovarian pregnancy is attributed to changes in the genital tract occurring as the result of pelvic infection. Proof of transmigration of the spermatozoa through the peritoneal cavity and ovarian maturation of the egg is demonstrated in the case described.

Amniotic Fluid Embolism as Cause of Death During and After Delivery. I. Martin. Geburtsh. u. Frauenh. 16:463-472 (June) 1956 (In German) [Stuttgart, Germany].

A 43-year-old woman was hospitalized for her fourth delivery. The course of the delivery seemed to be normal until she suddenly (about nine and one-half hours after onset of labor pains) complained of dyspnea and dizziness, became restless, and lost consciousness. In view of the increasing cyanosis of the mother, delivery was completed by forceps. Dyspnea and cyanosis continued after delivery, and the mother died despite all therapeutic measures. Autopsy revealed a patent foramen ovale. Compression of the cut surfaces of the lungs yielded granular particulate matter of yellowish color. The tentative diagnosis of embolism by amniotic fluid was confirmed by microscopic examination, which revealed the presence of elements characteristic of amniotic fluid in the lungs, heart muscle, and kidneys.

The author found 57 cases of amniotic fluid embolism reported in the literature. Rupture of the bag of waters seems to play an important part in its causation, because only after this occurs can amniotic fluid enter the maternal blood stream. Apparently, not every amniotic fluid embolism is fatal. Clinically, the diagnosis can only be suspected, and even at autopsy there is no macroscopic finding that corroborates this diagnosis; microscopic studies are generally necessary. A number of possible pathogenetic factors are mentioned. Embolism by amniotic fluid may escape detection because of the lack of characteristic symptoms. To obtain more information about its incidence, microscopic examination of the lungs should be carried out in every maternal fatality that occurs during or immediately after delivery. If the foramen ovale is found to be patent, the other vital organs should likewise be examined for the presence of the constituents of amniotic fluid.

PEDIATRICS

The Evolution of Infant Feeding and the Advantages and Disadvantages of Soured Milk Mixtures. W. B. Blue and W. C. Davison. Postgrad. Med. 20:41-48 (July) 1956 [Minneapolis].

The authors review the evolution of infant feeding and comment on the high mortality of artificially fed infants before the era of pasteurization, the numerous efforts to modify cow's milk, and the large number of proprietary infant foods available today. Particular attention is given to the work of Marriott, who simplified infant feeding by selecting soured whole milk or whole buttermilk (not the usual skimmed or fat-free commercial buttermilk) as a safe and digestible infant food. Marriott's original reason for using soured milk was that it diminished the work of digestion. Later, he suggested that its bactericidal action made it safer. A review of the various methods of feeding full-term and premature infants, both those who were normal and those who were ill and could not be breast-fed, led the authors to the use of evaporated milk soured with lactic acid at Duke Hospital of Durham, N. C. Lactic-acid evaporated milk can easily be prepared in the home from canned milk and it has many advantages.

Infants thrive on lactic-acid milk as well as they do on breast milk. Lactic-acid evaporated milk contains sufficient protein and calcium, but every child who is less than 3 years old should be given vitamins C and D. The milk is safe, because the evaporation process removes the risk of brucellosis, tuberculosis, typhoid fever, and other diseases that can be spread through dairies. The modification of the milk proteins by the evaporation process and acidification is also helpful for allergic infants. The addition of lactic acid prevents the growth of organisms that cause dysentery and of species of Salmonella with which flies or fingers may contaminate milk. Methemoglobinemia due to nitrate-containing well water does not occur in infants fed lactic-acid milk mixtures; this is a valuable asset in rural areas. The composition and quality of evaporated milk are much more constant than those of dairy milk. The cost of lactic-acid evaporated milk is half that of dairy milk or of many other infant foods. A disadvantage of lactic-acid milk is that concentrated lactic acid is poisonous, but using vinegar instead of lactic acid overcomes this difficulty. Some infants, especially those who previously have been fed with very sweet mixtures, dislike lactic-acid evaporated milk, but this difficulty can be overcome. All infants should be breast fed, not because human milk is necessarily better than other infant feeding mixtures but because it creates a sense of security and is of psychological advantage to the infants. When breast feeding is impossible, lactic-acid evaporated milk or vinegar evaporated milk is the best formula for infants.

The Effects of ACTH Given Intradermally to Infants with Hypertrophy of the Thymus. G. Zarbin and V. Baldi. Minerva pediat. 8:761-764 (June 2) 1956 (In Italian) [Turin, Italy].

Nine infants 3 to 16 months of age with hypertrophy of the thymus were treated for seven days with microdoses of corticotropin (ACTH). All except one were eutrophic. The characteristic symptoms presented were dyspnea, cyanosis, and postprandial vomiting. One child suffered a mild convulsive syndrome a few hours before admission to the hospital. Two had bronchitis and were given antibiotics before treatment with corticotropin. Radiological examination was made before and on the fourth and seventh days after the treatment. The clinical results differed from the radiological results. Symptoms disappeared in eight children after the treatment. Radiological observation showed that the size of the thymus had decreased in only three. Corticotropin was well tolerated. In some children the drug caused frequency of the bowels. The Thorn test was positive in five patients. In only two of these, the corticotropin therapy had reduced the hypertrophy of the thymus. The authors believe that intradermal administration of corticotropin in infants with hypertrophy of the thymus is of no particular value as far as reducing its size is concerned. Coritcotropin had only a general stimulating effect.

Considerations on the Use of Chlorpromazine in the Prophylaxis and in the Therapy of Transfusional Reactions. A. Coletta and F. Iafusco. Pediatria 64:236-244 (April) 1956 (In Italian) [Naples, Italy].

The authors studied the effect of chlorpromazine on a post-transfusional reaction syndrome characterized by shivering and hyperthermia. The syndrome is caused by the pyrogenic or the allergic effect of the transfused blood. It is centered in the neurovegetative system. Chlorpromazine in a therapeutic dose of from 1 to 3 mg. per kilogram of body weight per day does not have any significant side-effect. The effect of the drug was studied in 25 children from 4 months to 10 years of age. They had dystrophic syndromes or different types of anemia. The quantity of blood transfused was from 50 to 200 cc. Twenty children suffered the classic symptoms of the syndrome. Ten minutes or more after the transfusion they started shivering and trembling, became pale, had cyanosis and headache, and vomited. Temperatures rose suddenly to 102 and 104 F (38 and 40 C). Two children had some hypotension. Five children had intense pruritus followed by an eruption on the skin. A dose of 4 mg. per kilogram of body weight per day was given. The symptoms were checked soon after the first intake of the drug. The temperature became normal in about one hour. The drug caused drowsiness and perspiration. Breathing became less frequent and deeper. The prophylactic effect of the drug was studied in 30 children who had previously suffered transfusional combined with allergic reactions. A dose of 4 to 8 mg. was given to 20 children half an hour before the transfusion. The other 10 children were kept as a control group and did not receive the drug. Two children in the experimental group had mild and short post-transfusional reactions. Seven children in the control group suffered the classic effect of the post-transfusion reaction syndrome.

DERMATOLOGY

Contact Sensitivity to Inappreciable Exposures. F. C. Combes and G. E. Morris. Indust. Med. 25:289-290 (June) 1956 [Chicago].

This paper emphasizes the limited exposure that induces in some patients a recurrence of an eruption due to allergens to which they have been previously sensitized. The first of the patients had been employed by a manufacturer of antibiotics for nine months when a dermatitis of her hands, wrists, forearms, and face, for which she was hospitalized, developed. As the dermatitis was attributed to contact with penicillin, her job when she returned to work was restricted to packing sealed ampuls. Nevertheless, she experienced a recurrence almost immediately, and it became necessary to discontinue all contact with penicillin. Subsequently, however, she experienced recurrences of urticaria or dermatitis when she only shared a room with a patient who received an injection of penicillin or when she used the same toilet as a person who had recently had an injection of penicillin. She could not even walk past the plant manufacturing antibiotics where she had formerly worked without having a recurrence of urticaria. A second patient, who had also become sensitized to penicillin while working in the production of antibiotics, experienced a recurrence of conjunctivitis and periorbital dermatitis after working next to a girl who was sucking a penicillin lozenge.

Another case of extreme sensitivity concerned a man in whom a contact dermatitis had developed after working with naphtha; later the eruption recurred merely from entering a building where solvent fumes were present. Another man, who had become sensitized to phenol formaldehyde resins, had a recurrence of a vesiculoerythematous eruption after he talked to his coworkers, who had the fumes on their clothing. In a boy with a history of atopic dermatitis, the odor of lobster caused swelling of eyes and face.

THERAPEUTICS

The Effect of BZ-55 on Biochemically Uncontrolled Diabetes Without Insulin Treatment. B. S. Leibel. Canad. M. A. J. 74:979-982 (June 15) 1956 [Toronto].

A series of clinical trials with BZ-55 is presented. The five diabetic patients selected were those who might be presumed to have enough endogenous insulin to preserve clinical stability in the presence of protracted and abnormal biochemical findings. The method of investigation consisted of a comparison of blood sugar levels before and after BZ-55 therapy was instituted. Although their diseases were clinically similar, only three of the five patients responded to therapy. Maximum benefit from BZ-55 may be delayed for longer than two weeks.

Experience with Reserpine in the Treatment of Alcoholism. N. S. Ritter. Quart. J. Stud. Alcohol 17:195-197 (June) 1956 [New Haven, Conn.]

The present study was not concerned with the effect of the alkaloid reserpine on the acute alcoholic state but rather on the patients' drinking behavior over a period of time. The aim was to discover whether or not the drug exerted any specific action on psychological mechanisms operative in alcoholics. The patients were referred to the clinic by the magistrates of the home term court in New York City. Each patient was seen one evening per week by the internist assigned to the clinic. The patient was asked how he felt, if he was taking the prescribed medicament, and how many drinks he would estimate he had had during the preceding week. The only objective physical evaluation made was a blood presure reading. The patient was given a week's supply of medicament. Patients were randomly selected and given either reserpine or a placebo. Among 180 alcoholics studied during a one-year period, the effect of reserpine could be compared in 39 with the effect of a placebo in 36 controls. Although a sizable majority of both groups of patients seemed to improve, no decided difference between them was discernible. Both groups seemed to do better than before the start of therapy. During the past two years other forms of oral therapy have been used for similar patients, and the impression was that the fact that the patient is seen weekly and has some personal interest taken in his condition and that there is some form or oral therapy—be it with vitamins, a placebo, or reserpine—helps patients to cut down considerably on their drinking.

Synergism Between Meperidine (Demerol®) and Scorpion Venom. H. L. Stahnke. Arizona Med. 13:225-227 (June) 1956 [Phoenix, Arizona].

Physicians who have had experience with patients who have sustained scorpion stings have noted an increase in convulsive activity after the administration of morphine. Death in some of these cases should not be attributed to the scorpion venom alone but rather to the combined action of these agents. When similar reactions were reported following the use of meperidine (Demerol), the author made a pilot test of this combination, the results of which suggested a synergistic effect between meperidine and the venom of the scorpion, Centruroides sculpturatus. Experiments on rats revealed that, whereas the median lethal dose of C. sculpturatus venom alone is 0.96 mg. per kilogram of body weight in the rat, the median lethal dose of the venom drops to 0.714 mg. per kilogram when 50 mg. per kilogram of meperidine is administered, and when 100 mg. per kilogram of meperidine is administered the median lethal dose drops to 0.387 mg. per kilogram. This venom, as well as that of the rattlesnake (crotalus), is a neurotoxin, and neither morphine nor meperidine would be desirable analgesic agents for patients who have been poisoned with such toxins, at least not during the first 24 hours after the venenation. Consequently, the use of these analgesics is also inadvisable whenever a patient has suffered a venomous sting or bite and the offending animal has not been identified.

The Use of Aramine in Clinical Shock. G. H. Stechel, S. I. Fishman, G. Schwartz and others. Circulation 13:834-836 (June) 1956 [New York].

The use of metaraminol bitartrate (Aramine), a sympathomimetic amine [levo-1-(m-hydroxyphenyl)-2-amino-propanol] in normal subjects in 1951 had indicated the effectiveness of this drug as a vasopressor agent and had suggested certain advantages over other commonly used vasopressors. Aramine has now been used in 250 patients with clinical shock admitted to the first division medical service, Kings County Hospital Center, Brooklyn, N. Y. A group of 42 patients studied included a high percentage of poor-risk patients. It was found that, with administration of 300 mg. of the drug per 1,000 ml. of 5% dextrose in water, a rise in blood pressure to adequate levels could be anticipated within five minutes. Lack of response within 10 minutes usually indicated complete failure of vasopressor therapy. In many instances, therapy with Aramine was maintained for long periods of time (24 days in one case). It was noted that, after withdrawal of Aramine, the blood pressure gradually fell to levels that caused some alarm, and it seemed advisable to readminister Aramine immediately. It was found, however, that reinstitution of therapy was unnecessary in most instances, for the blood pressure gradually became readjusted to the withdrawal of the pressor agent over a period of hours. Advantages of Aramine over other pressor agents in the pilot study were verified in the present study, and several new advantages were noted, such as the fact that the blood pressure rose rapidly to the desired level, but not to the excessive levels so often observed with other pressor agents. When Aramine was withdrawn, the fall in pressure was a gradual one over a period of from 10 to 15 minutes, as contrasted with the precipitous drop in pressure often seen on withdrawal of other pressor amines. This characteristic is of particular advantage in cases where extended therapy is necessary. In no instance was there any deleterious result from infiltration of the tissues by infusion fluid containing Aramine.

PATHOLOGY

Amino-Aciduria in the Megaloblastic Anaemias. K. J. Keeley and W. M. Pohtzer. J. Clin. Path. 9:142-143 (May) 1956 [London, England].

Keeley and Pohtzer examined the urine of seven African women who were hospitalized with proved megaloblastic (but not pernicious) anemia before treatment was started. One-dimensional chromatography on urine specimens obtained in the morning showed normal amounts of amino acids. The control specimen of urine from a European patient with untreated pernicious anemia showed an excess of amino acids. The authors suggest that urinary chromatography be used to differentiate Addisonian from other megaloblastic anemias.

The Blood Pyruvic Acid Level in Renal Diseases and in Uraemic Coma. J. Kleeberg and S. Gitelson. J. Clin. Path. 9:148-152 (May) 1956 [London, England].

Sixty patients were examined with the aim of ascertaining whether pure renal diseases alter the normal blood pyruvic acid level; whether kidney diseases change the known response of the blood pyruvic acid level in other disorders; whether the blood pyruvic acid level in patients with uremic coma is different from that in patients with other kinds of coma who do not exhibit signs of renal failure; and whether hypertension, which is present in the majority of patients with nephritis, influences the blood pyruvic acid level by itself. The determination of blood pyruvic acid levels revealed normal values in 24 of 26 patients with uncomplicated chronic nephritis and chronic urinary infection regardless of whether the renal function was impaired or not. Even in patients with uremic coma and severe acidosis, the blood pyruvic acid level was at most at the upper limit of normal. The blood sugar values were normal in these patients, and no glycosuria was found. Normal blood pyruvic acid and blood sugar values were also found in 16 patients with essential hypertension who had no signs of renal damage or complications.

Elevated blood pyruvic acid levels in renal disease were obtained only in four patients who also had severe complications, such as cerebral hemorrhage, hypertensive encephalopathy, or pulmonary edema. The hyperpyruvicemia in them was accompanied by hyperglycemia and was regarded as a "stress" phenomenon. Hyperpyruvicemia was also present in six patients with cerebral coma and in eight patients with hepatic coma who had no signs of renal insufficiency. The excretion of pyruvic acid in the urine in five uremic patients was within normal limits. It is concluded that renal disease per se is unlikely to influence the blood pyruvic acid level. When hyperpyruvicemia occurs in patients with renal disease, especially in those in coma, it is presumed to be due to some other disorder known to cause hyperpyruvicemia. The level of the pyruvic acid in the blood may be of aid in the differential diagnosis of various types of coma. Pyruvic acid seems not to be a causative factor in renal acidosis.

RADIOLOGY

Practical Aspects of the Problem of Protection Against Radiation in General Roentgen Diagnosis. F. Fossati. Minerva med. 47:749-754 (March 17) 1956 (In Italian) [Turin, Italy].

Local and general biological injury is caused by excessive radiation in roentgen diagnosis. The effects manifest themselves late and may be hereditary. Protection is possible if necessary precautions are taken. Some of the effects are superficial lesions, hematological and hemapoietic alterations, formation of malignant tumors, obesity, reduction in fertility, and shortening of the length of life. The permissible professional maximal dose is 0.3 r per week, or, 48 hours of work per week. A special instrument measuring the radiation should be always worn by the radiologist. Lead should be interposed between the operator and the mechanism for radiation when it is not possible to keep at a safe distance. Protective measures could be introduced into the machines for roentgendiagnosis. Operators should wear special protective garments. Tubes should be covered with protective material. Intensity of radiation should not exceed 100 mr/h. at a distance of 1 m. from the focus. Radioscopy should be brief, with maximal opening of the diaphragm. Radioscopy with non-self-centering ducts must be avoided. The operator must be accustomed to the radioscopic vision from the beginning of the examination. Filtration and the distance from skin to the focus should be increased in order to protect the patient. Maximal radiation doses per exposure should be 0.1-0.2 r for the thorax, 2-3 r for the skull, 3-4 r for the digestive system, and 2-4 r for the spine; for kymography of the heart, the maximal dose should be about 4 r.

Nephrocalcinosis in Poliomyelitis with Respiratory Paralysis, with Special Regard to Possibilities of Tomographic Diagnosis. R. Stenstrom. Nord. med. 55:647-649 (May 10) 1956 (In Swedish) [Stockholm, Sweden].

Nephrocalcinosis was demonstrated by tomography in 9 of 32 poliomyelitis patients with respiratory paralysis admitted to Aurora Hospital between March, 1944, and January, 1955. The examinations were started in April, 1955. Eight patients were examined for the first time during respirator treatment after an average of six months in the respirator, calcinosis was established in four of these. Twenty-four patients, with an average of two months of respirator treatment, had been out of the respirator an average of six and a half months before the first examination. Of the eight, two patients with calcinosis and one patient without calcinosis have died. The calcinosis was most often in the cranial pole of the kidney. A certain relation seemed to exist between the degree of osteoporosis and the occurrence of calcinosis. Urinary infections were more frequent in the patients with nephrocalcinosis than in those without demonstrable calcifications. Nephrocalcinosis was often wholly or partly reversible after treatment. Application of tomography allows small calcifications to be discovered in an early and localized stage even though the patient's condition does not permit urography.

BOOK REVIEWS

Campbell's Operative Orthopaedics. Volumes I and II. Editor: J. S. Speed, M.D., Associate editor: Robert A. Knight, M.D. Third edition. Cloth. $40. Pp. 1103; 68; 1105-2124; 68, with 1323 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1956.

When the original volume was first written over 15 years ago by Dr. W. C. Campbell there was much comment about the value of the book. There had been a great need for this type of book in orthopedics, and the original book fulfilled that need well. With the many changes that took place during World War II, and as new procedures were established, revision was needed, and this was accomplished in the second edition. This third edition is perhaps the most outstanding book of its kind that has ever been published. The co-authors are to be congratulated for the excellence and completeness of the book. As in previous editions, the subject matter is excellently arranged and the illustrations are outstanding. The authors' decision to have special chapters contributed by eminent authorities adds to the general value of the work. The cost of these volumes is high, but, considering the amount of material contained in them, it is not excessive. The book should be made available to all universities and orthopedic departmental libraries for use of the house staff. It is an excellent reference book for practicing orthopedists and should be one of the first textbooks that the younger orthopedist purchases. Each chapter is a complete unit, and a given operative procedure can be reviewed without studying more than one or possibly two sections of the book.

Hunterdon Medical Center: The Story of One Approach to Rural Medical Care. By Ray E. Trussell, M.D., M.P.H., Executive Officer of Columbia University School of Public Health and Administrative Medicine, Columbia University, New York. Half-cloth. $3.75. Pp. 236, with 9 illustrations. Published for Commonwealth Fund by Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, England, 1956.

This well-written book is a fascinating story of the effort to solve the problem of community medical care in a rural county in New Jersey. The author was the first director of and had a close association with the project for five years. In the beginning, this county, with a population of 45,000 people, had no hospital within its confines. The planners of this project believed that there was a need for such an institution and proceeded with imagination and hard work to develop a center. It is interesting and informative to read about the early experiences in the education of the people of this county regarding the needs for good medical care. Equally interesting is the emphasis on the fact that here was an opportunity to set up a center that would play an active part in providing comprehensive medical care for the citizens of the county and that, in addition, would focus attention on preventive medicine.

There are many details in this book concerning the period of development of the center—such as the effort that produced a successful financial campaign, which could be profitably followed by other communities considering the same problem, and the extent to which the people contributed even in a small way. The fundamental principles included attracting more general practitioners, having the patients in the area remain in their community for their comprehensive medical care, and enabling the institution to carry on research concerning the health of the citizens. Another important feature was the affiliation with the New York University Medical Center, in regard to both the reference of patients and the rotation of the house staff from the New York University to the center. The latter proved to be of mutual benefit. The extent to which the community has participated in the everyday running of the center is evidenced by the fact that there are so many volunteers working in the hospital.

There is so much of interest and there are so many stimulating ideas in this book that it would be wise for those contemplating the establishment of community hospitals to read it. In this day of emphasis on community action in the problems of medical care, long-term illness, and preventive medicine, this book should be invaluable. It represents not only planning but also actual experience over a two-or-three-year period since the center was established. The last chapter is devoted to the accomplishments of the center and to a frank discussion of the problems that are yet unsolved. The experiment represents a valuable contribution to the question of community medical care and clearly points the way to possible practical application of this experience to any rural community.

The Pregnancy Toxemias or the Encymonic Atelositeses. By G. W. Theobald, M.A., M.D., F.R.C.S. With chapter on Adrenal Cortex by John Dawson, M.B., Ch.B., M.Sc. Cloth. $15. Pp. 488, with 56 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1956.

The author has presented the basic facts about the toxemias of pregnancy and has collected an extensive bibliography from which he has quoted freely. The book is divided into four parts. In the first are discussed the physiology of normal pregnancy, capillary circulation, water metabolism, edema, water diuresis during pregnancy, blood pressure, essential hypertension in the nonpregnant and pregnant woman, and the relationship of the posterior pituitary gland and the adrenal cortex to normal pregnancy. The second part has a chapter devoted to the toxemias of early pregnancy and another chapter to accidental hemorrhage, but the bulk of this section is devoted to the histological pathology of eclampsia and changes in metabolism leading to this disease. The third part is devoted to the various hypotheses that have been advanced to explain eclampsia. One chapter is devoted to the mechanical theories and another to the toxemic theory. The endocrine glands as a causative factor are discussed, and the relationship of the crush syndrome and renal ischemia are considered in another chapter. Three chapters are devoted to the placental hypothesis and four to the nutritional mechanical hypothesis. The fourth part deals with antenatal care in the prevention of eclampsia. One chapter deals with the treatment of preeclampsia, and four chapters are devoted to the treatment of eclampsia. The book is well written and sets forth clearly the present state of our knowledge regarding this disease. One might disagree with the recommendation of spinal anesthesia and/or lumbar puncture in the treatment of persons with severe eclampsia. The maternal mortality of 5.6% with treatment by a modified Stroganoff method under the author's management is not impressive. The use of local infiltration anesthesia in various operative procedures is not sufficiently stressed. The danger of blood transfusion in persons with eclampsia should be mentioned, and the value of venesection is underestimated. The overuse of hypertonic glucose solution is properly criticized.

Essentials of Dermatology. By Norman Tobias, M.D., Dermatologist, St. Louis State Hospital, St. Louis. Fifth edition. Cloth. $8. Pp. 651, with 212 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; 2083 Guy St., Montreal, Canada, 1956.

This textbook should remain popular with medical students and practitioners, as it has through four previous editions. The paragraphs, at the end of each chapter, on nursing aspects should make it of value to nurses also. The author has concentrated on the dermatoses encountered most frequently in practice, but he also discusses briefly many of the less common skin diseases. The rarities have been omitted. A surprising amount of information has been packed into a relatively small volume and presented in a very readable manner. Of particular value is the chapter on dermatological therapeutics, in which the author explains the general principles of topical and physical therapy and presents numerous therapeutic maxims reflecting a wealth of clinical experience. In this edition the chapters on the most common dermatoses have been expanded, the sections on therapy have been brought up-to-date, and 25 new photographs have been added. An occasional minor change in text might be suggested, such as more exact specification of dosage in a few sections and elimination of an occasional vague expression such as "general tonic treatment." In most places, however, discussions of therapy are current, specific, and adequate. These comments in no way detract from the general merit of the book, which can be recommended.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

Angiocardiographic Interpretation in Congenital Heart Disease. By Herbert L. Abrams, M.D., Assistant Professor of Radiology, Stanford University School of Medicine, San Francisco, and Henry S. Kaplan, M.D., Professor of Radiology, Stanford University School of Medicine. Publication number 279, American Lecture Series, monograph in Bannerstone Division of American Lectures in Pediatrics. Edited by John A. Anderson, M.D., Professor and Head, Department of Pediatrics, School of Medicine, University of Minnesota, Minneapolis. Cloth. $11.75. Pp. 233, with 163 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1956.

This book is based on a series of 350 angiocardiograms that cover almost all the various types of congenital cardiac defects. The angiocardiographic reproductions are excellent. Adjacent to each angiogram is a detailed black and white diagram with complete text clearly indicating the author's interpretation. An entire chapter is devoted to each congenital cardiac defect, including a brief but concise discussion of the pathological physiology and clinical features. This is then followed by the illustrations and the text on the angiocardiographic interpretation. Another chapter is devoted to technique, equipment, opaque mediums, and principles of angiocardiographic interpretation. This should be read by all who contemplate doing this type of work. Although the volume is small, it is filled with valuable information for those interested in opaque visualization of the heart and great vessels.

Modern Treatment Yearbook 1956: A Yearbook of Diagnosis and Treatment for the General Practitioner. Edited by Sir Cecil Wakeley, Bt., K.B.E., C.B., Senior Surgeon, King's College Hospital, London. Cloth. $6. Pp. 344, with 47 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; published for Medical Press by Baillière, Tindall & Cox, Ltd., 7-8 Henrietta St., Covent Garden, London, W.C.2, England, 1956.

This book is a symposium of the views of British clinicians on current methods of diagnosis and prevention of disease and forms of treatment. Thirty-seven contributors have each provided a chapter that deals with one of the many pathological conditions and medical problems commonly encountered in general practice. A chapter discussing the use of antibiotics is included. Some of the chapters are followed by references for collateral reading. A general index is provided at the end, with principal page references in bold-face type. For the most part the discussions are critical and are written with the simplicity and clarity of style for which the British are noted. In some instances the comments seem more appropriate for students than for experienced clinicians. British trade names and preferences in nonproprietary terms that are applied to certain drugs limit the usefulness of the book for American readers. The book does not mention some of the newer drugs known to American physicians nd thus cannot be regarded, for American doctors, as entirely epresentative of current knowledge in this field.

Clinical Laboratory Diagnosis. By Samuel A. Levinson, M.S., M.D., Ph.D., Director of Laboratories, University of Illinois Research and Educational Hospitals, Chicago, and Robert P. MacFate, Ch.E., M.S., Ph.D., Chief, Division of Laboratories, Board of Health, City of Chicago. Fifth edition. Cloth. $12.50. Pp. 1246, with 244 illustrations. Lea & Febiger, 600 Washington Sq., Philadelphia 6, 1956.

This book has now passed through sufficient editions to become familiar to those interested in laboratory medicine. It contains a wealth of material for the person in the laboratory as well as for the man in practice and provides a useful and practical source of reference on a host of subjects ranging from laboratory findings of special interest in relationship to the mouth to those in connection with the gastrointestinal tract and the kidneys. Also included is a great deal of information pertaining to metabolism, the blood, immunology and serology, cerebrospinal fluid, transudates and exudates, and the sputum. Those interested in general bacteriological skin tests and other biological examinations, laboratory methods in pediatric procedures, tropical diseases, milk and water analysis, histological techniques, and legal medicine and toxicology likewise will find much of practical importance. In addition to the two authors, there are five collaborators bringing special knowledge from their respective fields. This book deserves the attention it undoubtedly will receive from practitioners and laboratory personnel.

Progress in Hematology. Volume I. Edited by Leandro M. Tocantins, M.D., with 27 contributors. Cloth. $9.75. Pp. 336, with illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1956.

This summary of the present status of certain developments in hematology consists of 16 well-documented articles written in textbook style. There has been no such summary since Piney's book in 1927. The subjects covered are the absorption of vitamin B_{12}, parenterally administered iron, exchange transfusion in erythroblastosis fetalis, the life span of erythrocytes, abnormal hemoglobin, radioactive colloidal gold in the treatment of severe acquired hemolytic anemia, radioactive phosphorus in primary polycythemia vera, autoimmune thrombocytopenias, surgery in hemophilia, acute fibrinogen deficiencies, factors affecting hemostasis in gastrointestinal hemorrhage, the blood in lupus erythematosus, chemotherapy of leukemia, the biochemistry of leukocytes, hematological recovery from irradiation injury, and agammaglobulinemia. The material is well presented and gathers, in convenient form, data widely scattered in medical journals. The book should be welcomed by all workers interested in hematology.

Modern Trends in Orthopedics (Second Series). Edited by Sir Harry Platt, LL.D., M.D., M.S., President, Royal College of Surgeons of England, Manchester. Cloth. $12.50. Pp. 331, with 226 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1956.

This is the second volume dealing with modern trends in orthopedics and is part of a series of books that includes each of the major fields of medicine and surgery. Each of the orthopedic volumes was edited by Sir Harry Platt, who states in the introduction: "In this new volume, a number of topics of contemporary interest have been deliberately selected in order to focus attention on problems less widely ranging than those which form the content of the first series of Modern Trends in Orthopaedics." The text is beautifully written and printed, and the illustrations are clearly reproduced. The various chapters deal with reconstructive surgery of the hip, peripheral nerve injuries, the role of antibiotics in the treatment of bone and joint tuberculosis, congenital dislocation of the hip, muscle and tendon transposition in poliomyelitis, internal derangements of the knee, traumatic paraplegia, Pott's paraplegia, displacement of the upper epiphysis of the femur, contractures of the hand, and fractures of the neck of the femur. This is a book that all orthopedists should have in their library.

Collagen Diseases Including Systemic Lupus Erythematosus, Polyarteritis, Dermatomyositis, Systemic Scleroderma, Thrombotic Thrombocytopenic Purpura. By John H. Talbott, M.D., Professor of Medicine, University of Buffalo School of Medicine, Buffalo, New York, and R. Moleres Ferrandis, M.D., Training Fellow in Arthritis of Western New York Chapter of Arthritis and Rheumatism Foundation. Cloth. $6.50. Pp. 232, with 30 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1956.

This monograph is the culmination of the interest that the senior author has had in collagen diseases for many years. It is a concise description of these maladies, covering the historical, pathological, and clinical aspects and treatment. The colored plates are beautifully illustrative of the subject matter. The manuscript is well written, with a personal touch that makes for easy reading. Factual statements are supplemented with ample references, and the bibliography is more than adequate. The earnest enthusiasm with which the material is presented makes this monograph outstanding. This book can be highly recommended to those interested in collagen and rheumatic diseases.

The Biochemistry and Physiology of Bone. Edited by Geoffrey H. Bourne. Cloth. $20. Pp. 875, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1956.

This book, each chapter of which has been prepared by one or more recognized authorities, includes the best of most of the research that has been done in the field of biochemistry and physiology of bone during the past 25 years. Twenty-eight scientists have participated in writing it. The editor is widely known for his interest in this subject and has succeeded in producing a well-ordered arrangement of the material. There is an extensive bibliography and an author index as well as a subject index. This is a reference book rather than a textbook, and it should be of great value to every student or teacher who is interested in a better understanding of bone in health and disease.

QUERIES AND MINOR NOTES

ACETYLSALICYLIC ACID (ASPIRIN) AND ANTICOAGULANTS

To the Editor:—*What is the relative effect on clotting time of acetylsalicylic acid (aspirin) and the anticoagulants usually prescribed, such as Dicumarol. If acetylsalicylic acid is effective in this respect, what may be considered comparable dosage? Presuming that there is a comparable dosage, is there likely to be any untoward effect using such dosage of acetylsalicylic acid? Clinicians have said that there is almost never a vascular thrombosis (coronary included) when the clotting time is high. Please give an opinion on this.* *M.D., Pennsylvania.*

Answer.—Link and associates (*Am. J. Physiol.* 159:40-46, 1949) demonstrated that salicylic acid in the rat induces a hypoprothrombinemia that can be prevented by natural or synthetic vitamin K. In the rat the potency of salicylic acid was only about one-twentieth that of Dicumarol. S. Shapiro and his co-workers (*Proc. Soc. Exper. Biol. & Med.* 53:251-254 [June] 1943) demonstrated that the fundamental observations made on the rat also apply to man. Significant hypoprothrombinemia, similar to that produced by therapeutic doses of Dicumarol, has been observed after administration of 6 to 10 gm. of salicylates daily. With continued administration of salicylates, the prothrombin time tends to return to normal. Since the dosage of salicylates necessary to produce a hypoprothrombinemia that could prevent thrombosis is high enough to give rise to toxic effects on the central nervous system and to a disturbance of the acid-base balance or of the electrolyte structure of the plasma, it would appear hazardous to use salicylates for the induction of a therapeutic hypoprothrombinemia. Experience has shown that the incidence of thromboembolic phenomena can be greatly reduced by the judicious use of anticoagulants such as Dicumarol. However, on occasion, thrombosis has been observed to occur while the patient's prothrombin time was kept within the protective range of hypoprothrombinemia.

SEDATION BEFORE ELECTROSHOCK THERAPY

To the Editor:—*I would appreciate advice as to whether a mental patient, receiving electroshock therapy with succinylcholine (Anectine) chloride, should receive previous sedation with a barbiturate. If so, which kind and what dosage would be recommended?* *M.D., Nebraska.*

Answer.—The decision as to whether a patient should receive sedation previous to electroshock therapy should be made independent of whether the therapist administers succinylcholine. The administration of a sedative drug should be indicated by the patient's anxiety concerning the treatment. There are some patients whose anxiety states require sedation, with or without muscle relaxant; with other patients it is unnecessary. For short procedures such as electroshock therapy, intravenously given barbiturate and, above all, thiopental sodium are the drugs of choice. Since the effect of succinylcholine develops before that of the intravenously given thiopental sodium, it is preferable not to give both drugs at the same time. Another important point is that succinylcholine is hydrolyzed by alkaline solutions such as the solution of thiopental sodium; therefore, the solution of succinylcholine should not be mixed with the solution of the thiopental sodium in the same syringe. When administering the combined medication of thiopental sodium and succinylcholine, the dose of the succinylcholine judged to be adequate for the patient has to be determined. A test dose of 10 mg. may be given to serve as a guide to the patient's requirements and the promptness of his recovery. If this dose produces only the relaxation of the eyelids, or of the extremities (a moderate relaxation), then the patient usually requires 20 mg. for an adequate effect, while the patients who show only minimal relaxation after the test dose probably require 30 to 40 mg. The satisfactory method of induction of anesthesia is to administer the thiopental sodium slowly, until the eyelid reflex is abolished. At this time the dose of succinylcholine can be given through the same needle but from a different syringe. When both thiopental sodium and succinylcholine are administered, the aim is to adjust the dose of each drug so that the convulsion is a slight one and is followed almost at once by the return of active breathing. It seems, according to Price and Rogers (Correspondence, *Brit. M. J.* 1:1027, 1952), that, owing to the rapid action of succinylcholine, a smaller dose of thiopental sodium can be used than with other relaxants. As to the time element, the injection of succinylcholine should follow the injection of the barbiturate in 10 seconds to two minutes. After administration of the succinylcholine, the lungs are inflated with oxygen for 45 seconds; a gauze roll is then placed between the teeth, the relaxed jaw is held against it, and the electroshock therapy is given at once. It is needless to emphasize that either thiopental sodium or succinylcholine may produce respiratory arrest. Therefore, they should be used only by those skilled in the administration of controlled respiration and endotracheal intubation and only when facilities for these procedures and for adequate respiratory exchange with oxygen are immediately available.

CONJUNCTIVAL SENSITIVITY TO TOBACCO SMOKE

To the Editor:—*What is the best treatment for a conjunctival hypersensitivity to tobacco smoke? This condition has developed gradually in a 47-year-old woman who has a history of allergy to timothy grass and orchard grass pollens. Her vision is hyperopic and somewhat astigmatic, which is easily corrected by glasses. Examination of the conjunctivas shows them to be infected at such times. They gradually return to normal, but the symptoms recur regularly each time she is exposed to this irritant. She has shown some favorable although transitory response to treatment with cortisone eye drops.* *M.D., New York*

Answer.—Treatment of conjunctival hypersensitivity should include: (1) avoidance of tobacco smoke, both use and exposure; (2) local application of antihistaminics such as prophenpyridamine maleate, with or without cortisone; (3) patch tests and desensitization; (4) oral use of antihistaminics such as chlorprophenpyridamine maleate; and (5) appropriate treatment of structural and functional ocular and extraocular disease. The treatment of the secondary infection obviously depends on the organisms involved. A stained conjunctival scraping should be made to determine cells and organisms.

SLIDE CULTURE FOR TUBERCLE BACILLI

To the Editor:—*Please describe the technique of the "slide culture method" for demonstrating Mycobacterium tuberculosis. How does the accuracy of the slide culture compare with that of the usual cultural methods?* *M.D., Ohio.*

Answer.—Following is the technique of the "slide culture method" as described by Pryce (*J. Bact. & Path.* 53:327, 1941). Method 1: A 4-in. Petri dish is selected with a flat or slightly hollow bottom surface. The sputum is spread on this and dried. The film is treated with 15% sulfuric acid for five minutes. The acid is removed with a pipet and the floor flooded with about 5 cc. of sterile distilled water from a test tube. This is allowed to act for a minute or so and the washing repeated. The medium is then added and the dish placed in the incubator for a week. As medium, one can use 5 cc. of citrated blood and either 5 cc. of water, or, better, a 1% solution of saponin. When incubation is completed, the medium is washed off with water and the film

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

stained with Ziehl-Neelsen stain. Counter staining with methylene blue may be omitted. The culture is examined under the low power of the microscope while wet with water or xylene. Method 2: One or more circular patches of sputum are smeared on a glass slide and allowed to dry. A ring of Bakelite, hard fiber, or glass is immersed in melted petroleum jelly and, after draining off the excess, is applied to the glass about each patch of sputum. With a Pasteur pipet, 15% sulfuric acid is placed in the well of the ring, allowed to act for five minutes, and then removed. After the pipet is washed out, the well is filled with distilled water. Two or three washings suffice, but each change of water should be left in for a few minutes. After the final washing, the medium is added—anything from 5 drops to 1 cc. or more, according to the capacity of the ring. The culture may be incubated open to the air in a moist chamber, or closed by applying a coverslip previously immersed in petroleum jelly. Variations in this technique have been reported by Lowry and Berry (*Am. J. Clin. Path.* 20:273, 1950). The slide culture method is not as sensitive or efficient in detecting tubercle bacilli as the usual culture methods. It would not be satisfactory in a diagnostic laboratory doing large numbers of cultures. Probably its best use is in research work.

HIGH BLOOD CHOLESTEROL LEVEL

> TO THE EDITOR:—*A 31-year-old woman has had a high blood cholesterol level since October, 1951. Her blood cholesterol level was 411 mg. per 100 cc. in November, 1951. She was put on a rigid diet, and, in December, 1951, the cholesterol level dropped to 387 mg. per 100 cc., on March 23, 1955, it was 360 mg. per 100 cc. She has been checked every month since that time, and the lowest it has been is 310 mg. per 100 cc. The patient has been treated with Monichol since October, 1955, but the cholesterol level remains high. Could you offer any suggestions for treatment?*
>
> *Leland F. Zatopek, M.D., La Grange, Texas.*

ANSWER.—The response of the blood cholesterol level in the patient described to a rigid low-cholesterol diet is about what can be expected in the average patient. This relatively small drop in blood level is due to the fact that cholesterol can be synthesized by the body from simple foodstuffs, therefore, the dietary cholesterol is only a minor factor in the serum level. In addition to diet, thyroid may be effective in lowering the cholesterol level, particularly if some degree of hypothyroidism is present. No other established and satisfactory methods are at present available.

TREATMENT OF ASCARIASIS

> O THE EDITOR:—*What is the best treatment for persistent Ascaris lumbricoides? A man and wife, with no children, both have the infestation. Repeated treatment with Crystoids has yielded no results. How soon after Crystoid therapy should Ascaris disappear from the stool?*
>
> *Francis M. Lenhart, M.D., Defiance, Ohio.*

ANSWER.—Crystalline hexylresorcinol usually is considered the drug of choice in the treatment of ascariasis, but certain factors must be taken into consideration. 1. Potency of the drug. If the hard gelatin capsules are old they may not dissolve in the gastrointestinal tract and would therefore be ineffective. The preparation should be fresh and should dissolve high in the small intestine so all of the worms will be exposed to the drug. 2. Preparation of the patient. The patient should be on a light, residue-free diet the day before treatment and receive a saline purgative the night before treatment. Two hours after treatment is administered a second saline purgative is given. 3. Reinfection. Sometimes it is difficult to differentiate between failure of treatment and reinfection. If the infection has persisted for more than one year, reinfection has undoubtedly occurred, for the survival time of a mature Ascaris worm in the human intestine is relatively short, rarely exceeding a year.

Two other preparations have proved of value: piperazine (Antepar) citrate and Hetrazan (1-diethyl-carbamyl-4-methyl-piperazine citrate). Methods of treatment are as follows: 1. Crystalline hexylresorcinol (0.1-or-2-gm. hard gelatin capsules). Adult dose is 1 gm. in one dose, on an empty stomach, preceded and followed by a saline purgation as described above. 2. Piperazine citrate. Brown and Sterman (*Am. J Trop. Med.* 3:750 [July] 1954) report good results in children weighing over 60 lb. by giving piperazine citrate, 10 cc. (2 teaspoonfuls) twice daily for seven consecutive days. 3. Hetrazan. Etteldorf and Crawford (*J. A. M. A.* 143:797 [July 1] 1950) report excellent results using Hetrazan in a dose of 6 mg per kilogram of body weight three times daily for seven days. Ghanem (*Tr. Roy Soc. Trop. Med. & Hyg.* 48:73 [Jan.] 1954) reports good results using Hetrazan for 3 to 15 days. He states further that the migrating larvae of Ascaris probably are killed also. The advantage of piperazine citrate and Hetrazan is that the patient requires no preparation and no purgation. The advantage of crystalline hexylresorcinol is that the treatment is completed in one day. Reinfection should be prevented by proper personal hygiene and sanitary disposal of excreta. After the eggs are passed they become infective in 15 to 20 days but may remain viable on the soil for months or even years.

ANTIHYPERTENSIVE MIXTURES

> TO THE EDITOR:—*A man, aged 69, had a transient apoplectiform attack. His blood pressure is 230/100 mm Hg. Treatment with Mio-Pressin 1 brought his blood pressure down to 190/80 mm. Hg. He has been taking it now for 12 days. How long should he continue medication, and are there any dangerous side-effects?*
>
> *M.D., New York.*

ANSWER.—It would be undesirable to lower the arterial pressure beyond the point where it is now. This is a patient with arteriosclerotic hypertension in whom the diastolic pressure, as is to be expected, is not high. Too much lowering of pressure in such persons may lead to inadequate perfusion of the brain. Mio-Pressin, like any of the mixtures of antihypertensive drugs, fails to allow the flexibility of dosage of the individual drug components required for proper management of hypertension.

CANDIDA INFECTION OF BLADDER

> TO THE EDITOR:—*What is the best management of a 40-year-old woman with persistent Candida infection of the bladder, a normal upper urinary tract, and a few granulations about the neck of the bladder?*
>
> *M D., Texas*

ANSWER.—Persistent infection of the bladder caused by Candida occurs infrequently. On the other hand, Candida infection of the vagina is frequently observed, particularly during pregnancy. It may be assumed that infection of the bladder with Candida is secondary to similar infection of the vagina. It would, therefore, be advisable to eliminate the possibility of a persistent vaginal infection. Involvement of the bladder usually responds to lavage with a solution of gentian violet (1:1,500) or a weaker solution of acriflavine. Recently, a new drug, nystatin, has been found to be of value in treating Candida infection. Daily irrigations of the bladder with a solution made by dissolving one tablet of nystatin in a liter of water may be tried. Granulations of the neck of the bladder should be treated by topical application through the cystoscope with a 1% solution of gentian violet. It should also be remembered that bacteria commonly found with cystitis may be obscured by the Candida infection. Should these bacteria be discovered after the Candida infection has been removed, antibiotics should be administered according to the type of bacteria found.

PRECORDIAL PAIN IN MORPHINE ADDICT

> TO THE EDITOR.—*Seven months ago a 59-year-old morphine addict had an acute myocardial infarction. At present her condition is fairly good, but she still complains of periodic pain. Is it correct (according to the Federal Narcotic Law) to prescribe for her, at least from time to time, a narcotic for relief of pain?*
>
> *Julian Movchan, M.D., Oakwood, Ohio*

ANSWER.—The Federal Narcotic Law does not prohibit a physician from administering opiates to a former addict, or to an actively addicted person, for the relief of pain. The law requires that the physician prescribe or dispense narcotics "in the course of his professional practice only." This has been interpreted by the courts to mean that the physician must be acting in good faith, e. g., prescribing narcotics for what he believes will benefit his patient. The regulations set up to carry out the purposes of the narcotic law do prohibit the prescribing of narcotics for the mere maintenance of addiction, but this prohibition would not appear to apply in the case described. Although there is no legal reason why narcotics could not be given to the patient mentioned, careful consideration should be given to the actual need for narcotics. If the pain is that of angina, it could probably be relieved more quickly and more efficiently by glyceryl trinitrate than by morphine. Furthermore, *the repeated use of narcotics in any chronic disease* can lead to addiction. Since this particular patient is a former addict, the danger would be very great. The patient certainly should never be given narcotics for self-administration. In the event that the patient developed status anginosus or another infarct, opiates should, of course, be used. In such a situation the doses should be the smallest that would give an adequate degree of relief from pain. Additional doses should be given only as needed, and administration of the drug should be discontinued as soon as the patient's condition permitted.

PREPARATION OF SKIN FOR SURGERY

To the Editor:—*What antiseptic is most widely used now for painting the abdomen before surgery? Does thimerosal (Merthiolate) still hold first place, and what is its relative value in comparison to benzalkonium (Zephiran) chloride?*

M.D., Oregon.

Answer.—At present there are many agents for preparation of the skin of the operative site. Any one of these agents is satisfactory for this purpose if used properly. The area should always be cleaned well with soap and water the night before operation. If a chlorinated hydrocarbon is to be used, a soap containing this agent should be employed. In the operating room any one of the mercurial antiseptics, such as thimerosal, is a satisfactory preparation if the skin has first been cleaned with alcohol and ether. If a chlorinated hydrocarbon such as hexachlorophene is used, it is important that no other agent be employed after its application that might interfere with the protective film that is left by the chlorinated hydrocarbon. If a quaternary ammonium compound such as benzalkonium chloride or benzethonium (Phemerol) chloride is used, it must be remembered that these agents are inactivated by soap. Resorcinol compounds might be used, but these are not as good as the foregoing three groups of agents. If hexachlorophene is used, it is well to wet-wash the operative site with this agent for about five minutes; then the area should be painted with this agent and the excess dried with a sterile towel.

SENSITIVITY TO AMINOPYRINE

To the Editor:—*How does aminopyrine cause leukopenia or agranulocytosis? What, if any, are the chemical, enzymic, or vitamin changes in bone marrow, blood, or tissues before and/or during the development of granulopenia?*

M.D., Texas.

Answer.—When Madison and Squier (*J. A. M. A.* 102:755-759 [March 10] 1934) pointed out the relation between aminopyrine and the development of severe leukopenia they suggested it might be on the basis of drug sensitivity. Later, Dameshek and Colmes (*J. Clin. Invest.* 15:85-97 [Jan.] 1936) were able to produce extreme granulocytopenia in patients who had had previous attacks of the disease by injecting a small amount of the drug intradermally. It was postulated that the leukopenia occurred as a result of a sensitivity reaction in which a drug-protein linkage was involved. Moeschlin and Wagner (*Acta haemat.* 8:29-41 [July-Aug.] 1952) have done work suggesting that, as a result of this sensitivity, agglutinins are produced that cause striking agglutination of leukocytes. These, in turn, are filtered out rapidly in the lung. Moeschlin has shown that giving a patient sensitive to aminopyrine a small dose of the drug and then transfusing the patient's blood into a nonsensitive individual will produce a striking reduction in the leukocytes in the nonsensitive individual. The actual mechanics in changes in the bone marrow are probably on the basis of an emptying out of the cells from the bone marrow, so that, with prolonged administration of the drug after the reaction occurs, the cells in the marrow are at more and more immature levels.

KEROSENE SWALLOWED BY CHILDREN

To the Editor:—*Where liquid hydrocarbons, such as kerosene and furniture polish, have been swallowed by children, is gastric lavage indicated? If indicated, what technique will avoid the possibility of getting more of the hydrocarbon over into the trachea in the process?*

Harry D. Baernstein Jr., M.D., Racine, Wis.

Answer.—Current recommendations regarding gastric lavage in cases in which kerosene or related petroleum distillates have been swallowed by children are controversial. Experienced physicians make opposing recommendations for and against emptying the stomach. Reported experimental evidence is also conflicting and has been variously interpreted. A manual on accidental poisoning in childhood, published by the American Academy of Pediatrics but not an official academy statement, suggests that prompt and early lavage in cases of kerosene ingestion would be beneficial. If this lavage is carried out with the child properly restrained, flat on a table with the head lower than the feet (Trendelenburg position), the opportunities for getting the hydrocarbon into the trachea are considerably minimized. However, a substantial number of individual members of the Academy of Pediatrics and others feel this may increase the likelihood of tracheal aspiration and consequent pulmonary complications.

INTELLIGENCE TESTS

To the Editor:—*Where can I find the psychometric tests that are acceptable today and what they mean? Is the Minnesota multiphasic test one of these?*

A. L. Henricksen, M.D., Van Nuys, Calif.

Answer.—Psychometric test is a term generally applied to those tests that deal with the measurement of intelligence. The Minnesota multiphasic test is not an intelligence test but, rather, seeks to evaluate personality traits and classify the subject according to the pathological trends indicated by his response to the test. The most frequently used psychometric or intelligence tests are the Wechsler-Bellevue intelligence scale, forms I and II; the Wechsler adult intelligence scale; and the Wechsler intelligence scale for children. For children and adolescents the revised Stanford Binet (1937 revision) is also commonly employed. The personality tests in general use today are the Rorschach, the thematic apperception test, the Bender gestalt test, the Minnesota multiphasic test, and a number of sentence-completion tests. There are several books that deal with the theory and application of both the various intelligence and personality tests that are most frequently used in clinical practice today. Among these are "An Introduction to Projective Techniques" (Anderson, H., and Anderson, G.: New York, Prentice-Hall, Inc., 1951); "Projective Techniques" (Bell, J. E.: New York, Longmans, Green & Co., Inc., 1948); and "Appraising Personality" (Harrower, M.: New York, W. W. Norton, 1953). The textbooks indicated above, as well as the individual tests and test materials, are available from the Psychological Corporation, 522 Fifth Ave., New York.

TRANSFUSIONS

To the Editor:—*Can blood transfusions be given routinely with 5% dextrose solution running in the same tube at the same time? In surgery the anesthetist seems to prefer to give dextrose and saline solution in one bottle and blood in another, each connected by a wide tube to a single tube through which the infusion is given into a single vein.*

M.D., Alabama.

Answer.—It is inadvisable to give simultaneous infusions of dextrose solutions and whole blood. De Gowin and others (Blood Transfusion, Philadelphia, W. B. Saunders Company, 1949, p. 278) call attention to the danger of extravascular hemolysis resulting from the mixture of stored blood and dextrose solutions. Wilson (*Am. J. Clin. Path.* 20:667 [July] 1950) reports a transfusion reaction traceable to the clumping that occurs in a mixture of dextrose solution and citrated whole blood. Dreyfus and Salmon (*Presse méd.* 60:845 [June 7] 1952) point out the danger of clumping and of increased fragility of red blood cells exposed to dextrose solutions.

FEET OF DANCERS

To the Editor:—*An abstract in* The Journal *(Dec. 27, 1952, page 1732) on "Studies on the Feet of Dancers" indicated that the feet of children who performed modern dances nearly all were splayed or flat and that these children had other difficulties presumably due to the lack of proper support of the foot. A patient, aged 11, has been particularly active in this field, and I feel that her feet are gradually becoming more splayed and flat. How can further changes in the feet be prevented?*

M.D., New Jersey.

Answer.—Toe slippers will, of course, keep the foot narrow and small, but they tend to contract the foot and cause talipes equinus, talipes cavus, and contracture of the toes. This is true when the dancing is carried out over a long period of time. Modern dancing allows full, free use of the foot and increases its strength, but it does allow the foot to spread. If a child's foot is strained during this process, it, too, will be subjected to a type of deformity—usually hallux valgus. The idea in modern dancing is to have absolute freedom of the body, including the foot. Modern dancing when carried out on soft sand at the beach or on a lawn would not result in a deformity. It is conceivable that a shoe could be made that would prevent the foot from spreading. It would have to be soft-soled and laced. Instructors in modern dancing are of the opinion that unless the foot of a child is strained in dancing, the foot will not spread. If properly taught, modern dancing will increase the strength of the foot and improve the appearance. Exponents of modern dancing have well-appearing, perfectly normal feet to prove this. It would seem, therefore, that the best advice to prevent further changes in the feet of a child would be to permit a limited amount of dancing sufficient to increase the strength, but not sufficient to permit strain. It must be kept in mind that there are contributing factors to the spread of the foot besides the dancing. There may be an initial weakness or a congenital tendency toward flat feet, poor muscle tone, or excessive body weight.

DIETHYLSTILBESTROL FOR ORCHITIS

To the Editor:—*Would you please inform me as to the status of diethylstilbestrol in the prophylactic treatment of the orchitis secondary to mumps in males at and past the adolescent stage?*

Henry C. Zingher, M.D., Rushville, Ill.

Answer.—Hoyne, Diamond, and Christian (*J. A. M. A.* 362 [June 25] 1949) reported highly favorable results with use of 5 mg. of diethylstilbestrol daily in both prophylactic and therapeutic treatment of mumps orchitis. They observed a rather rapid therapeutic response, decrease in morbidity, and shortening of the convalescent period from three to five days. In none of their patients was operation necessary. Treatment is probably worthy of trial in some patients. Gellis, McGuinness, and Peters (*Am. J. M. Sc.* 210:661 [Nov.] 1945) used gamma globulin obtained from the convalescent mumps serum in a series of patients with mumps and obtained a significant decrease in orchitis.

CARE OF NEWBORN INFANTS

To the Editor:—*In this hospital a newborn baby is placed on the mother's abdomen and the cord is clamped with a Ziegler clamp and cut. The baby is then wrapped in a warmed receiving blanket and transferred to an electrically heated resuscitator, where suction of the oropharynx is performed After a variable length of time the baby is carried in the nurse's arms to the nursery, 122 ft. away on the same floor, and en route is shown to any of the family in attendance. The rectal temperatures of the babies so handled, on arrival in the nursery, are frequently in the 96-97 F (35.5-36.1 C) range. It has been suggested that an infant incubator be used in the delivery room to prevent heat loss by the newborn infant and that the baby be transported to the nursery still in the incubator. Any comments in reference to our present procedure would be appreciated.*

M.D., Virginia.

Answer.—In the "Standards and Recommendations for Hospital Care of Newborn Infants, Full-Term and Premature" (Evanston, Ill., American Academy of Pediatrics, 1954), section 6 on immediate care in the delivery room states, "A warmed incubator or heated bed is required for a newborn infant. This should be of a type approved by the Council on Physical Medicine of the A.M.A. and the Underwriters Laboratory as explosion proof." Under transfer to nursery is this statement: "Transfer should be by a route which is as free of contact with other persons as possible. There should be a moveable oxygen supply for infants whose respirations are not normal. A moveable heated bed should be available when needed."

SUBJECTIVELY AUDIBLE PULSATIONS

To the Editor:—*A 69-year-old woman with essential hypertension and relatively severe arteriosclerosis has been taking 0.1 mg. of reserpine twice a day. Her average blood pressure before treatment was 230/140 mm. Hg and is now 150/95. Her main problem is persistent throbbing in her head with each heartbeat. The throbbing is bilateral and worse at night. Barbiturates control this fairly well but are unacceptable to the patient because of the associated drowsiness. Is there any other treatment?*

Dale R. South Jr., M.D., Troy, Ohio.

Answer.—Awareness of the pulse, in the head, ears, or elsewhere in the body, occurs independently of arterial hypertension and/or arteriosclerosis as well as coincident to these disorders. It is not a symptom of circulatory impairment but is a common complaint in persons who are apprehensive about their health, particularly if the fears are focused on cardiovascular disease. In cardiac neurosis this symptom is frequent. Since it is subjective and associated more with apprehension of impending catastrophe than with actual present distress, it often resists therapy. Drugs are not the answer, nor is the answer simple reassurance without convincing explanation of the variability in somatic awareness associated with psychic stress. Careful inquiry regarding the onset of this complaint will usually reveal an association with some experience intensifying anxiety. The psychotherapy of the neuroses cannot be outlined here, nor would a general discussion be profitable. Each instance must be handled individually. It is most important that explanation of the insignificance of the phenomenon be clear, detailed, convincing, and sincere. If the awareness of the pulse is felt to be significant, anxiety is intensified and the symptom is perpetuated. Diversion of attention will more often than not erase the sensation. This can be used as objective evidence in instructing the patient.

SENSITIVITY TO ASPIRIN

To the Editor:—*In patients who are clinically sensitive to aspirin, what drugs may be safely employed as antipyretic and analgesic substitutes?*

M.D., California.

Answer.—Patients who are allergic to aspirin can usually take sodium salicylate, acetophenetidin, acetanilid, and aminopyrine. However, not infrequently such patients fail to tolerate some of these drugs also. Apamide (N-acetyl-*p*-aminophenol) is a good substitute for aspirin.

JOINT PAIN IN PATIENT WITH PURPURA

To the Editor:—*In* The Journal, *April 21, 1956, page 1438, is a question under the heading, "Joint Pain in Patient with Purpura." In the answer the consultant made an important omission of differential diagnosis. It seems to me that any patient receiving cortisone or related steroids, especially when therapy is continued for a long time, who develops symptoms of generalized bone and muscle aches and pains, should be considered first of all to have iatrogenic hypercortisonism or hypocortisonism. In the past this syndrome related to steroid therapy has not been properly recognized. It has been described by Slocumb in* Proceedings of the Staff Meetings of the Mayo Clinic *(28:655, 1953), by Freyberg in the book* "Corticotropin, Cortisone, and Hydrocortisone" *(Philadelphia, Lea & Febiger, 1953), and by Hench and Ward in "Medical Uses of Cortisone, Including Hydrocortisone and Corticotropin" (New York, Blakiston Company, 1954).*

Defense Department Seeking Medical Fee Data • •
Mintner Foresees New Drug Laws Next Year • •
AEC Official Reports on Radioisotopes • •
Selective Service Asks Residency Review • •

COLLECTION OF DATA ON MEDICAL FEES

The Defense Department, with the cooperation of the American Medical Association, is collecting nationwide information on prevailing medical care charges in each state as an essential step in putting into effect the new military dependent medical care program, which under the law is scheduled to be in operation by Dec. 8. All state medical societies are being supplied with copies of a department pamphlet, "Nomenclature for Proposed Medical Charges," and are being asked to (*a*) complete the schedule of charges as far as practicable, (*b*) indicate the geographical areas of the state in which charges apply if the state insists upon a variable fee schedule, and (*c*) send the form to Dr. George F. Lull, A. M. A. Secretary-General Manager.

The nomenclature consists of 115 pages listing and defining specific medical procedures. The state societies are expected to fill in the blank spaces with the charges prevalent for each. To facilitate collection of basic information, the societies are asked to first fill out charges for about 200 of the more common procedures, indicated by asterisks, with the remainder to be completed later. Navy Captain J. V. Noel, chairman of the Defense Department's task force handling the new program, points out in a foreword that in preparing the form extensive use was made of the A. M. A.'s Standard Nomenclature of Diseases and Operations, the California Medical Association's "Relative Value Schedule," and the Blue Cross-Blue Shield's "Actuarial Statistical Manual." The objective is to arrange for the care of military dependents who will not be cared for in military facilities. The department has tentatively decided to employ a system of reimbursement of physician's and hospital's charges plus the cost of administration to the agency selected to handle the hospital and medical facets of the program.

"This [fee] schedule applies only to services performed under the supervision of a physician," the department points out. "It is realized that the list is not all inclusive. For procedures not listed, or those for which it does not seem feasible to establish a charge but are within the scope of the law, payment may be made subject to a physician's report. Payment for treatment of non-surgical conditions will be on a hospital visit basis."

"Those procedures which are authorized to be performed by a physician for dependents who at the time is not a patient in a hospital are included in this schedule, but have not been listed separately. Prior to the effective date of this program, these specific procedures will be identified by the Secretary of Defense." Only outpatient care will not be furnished under the program, although a few procedures that can be carried out in a physician's office equally effectively as in a hospital are permitted.

ADDITIVES IN FOOD

Bradshaw Mintner, retiring Assistant Secretary of Health, Education, and Welfare, believes the next Congress will pass legislation to control additives in food. Mr. Mintner outlined his views in an address before the food, drug, and cosmetic law division of the American Bar Association. "This matter of chemical ingredients in food in my opinion is one of the really serious and important public relations problems of the foods industry," he said. "It will never be solved satisfactorily as long as there is any question or doubt that all food ingredients are not as completely safe as it is humanly possible to make them. The only solution, in my opinion, is a law that requires adequate testing for safety before the food additive is put on the market—and there should be no loopholes in this requirement."

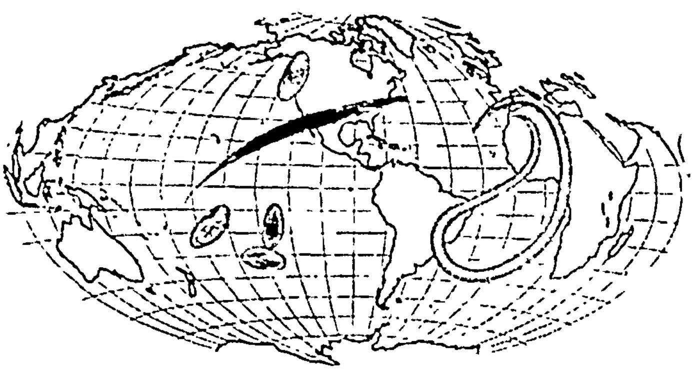
Mr. Mintner reviewed the long hearings on additives conducted by the House Interstate and Foreign Commerce Committee, noting that despite the clearly defined points of controversy the hearings showed there was a wide area of agreement as to the objectives of the proposed law. He said he believes there is every reason to expect a satisfactory law can be worked out by the next Congress. The Assistant Secretary disclosed that, although the last Congress increased appropriations for the Food and Drug Administration by a million dollars, most of this has been offset by increased costs of operations. The result is the addition of just five more budget positions in the FDA.

MEDICAL USES OF RADIOISOTOPES

Among some of the more outstanding contributions of the atomic age to medicine is the therapeutic use of artificially produced radioisotopes, reports Dr. Charles L. Dunham, director, division of biology and medicine, Atomic Energy Commission. Addressing the Rocky Mountain Cancer Conference, Dr. Dunham summarized ways in which radioisotopes are being used throughout the field of medicine. The internists are using radioactive phosphorus (P^{32}) and other radioisotopes to diagnose and treat a variety of diseases. Neurosurgeons are finding radioactive iodinated human serum albumin and radioarsenic important tools in the diagnosis and localization of brain tumors. Ophthalmologists, plastic surgeons, and genitourinary surgeons all find radioisotopes valuable in their practices.

(Continued on page 22)

From the Washington Office of the American Medical Association.



Washington News—Continued

The diseases of "maturity" become increasingly important as the methods for the control of the infectious diseases are more and more effective, Dr. Dunham said. Therefore, the possible future applications of tracer studies in intermediary metabolism hold promise for medical practice. "Precise knowledge of the various disturbances of carbohydrate, lipid and protein metabolism, so little understood today, will bulk large in our efforts to control atherosclerosis, hypertension and perhaps even neuropsychiatric disorders," he declared. Among the indirect contributions of the atomic age to medicine is the information on radiation effects on the biological system. Premature aging and cancer are two of the effects of overexposure to ionizing radiation, continued Dr. Dunham. The Oak Ridge Institute for Nuclear Studies and the Argonne Cancer Research Hospital at the University of Chicago School of Medicine are playing important parts in research into these problems. Dr. Dunham emphasized that, in the event of an atomic war, the physician must be prepared to evaluate and treat radiation casualties whether he is in military or civilian practice.

SELECTIVE SERVICE REVIEW OF RESIDENCIES

A bulletin from the headquarters of the National Selective Service urges state directors to review the files of all physicians in residency programs who have not requested deferment under the military or Public Health Service residency training programs. Directors are instructed to report their findings to the National Selective Service headquarters. "It has been noted that some physicians who have completed internships and are in residency training but who are not in a residency training program of the Armed Forces or the Public Health Service have been given occupation deferments," the bulletin says. "It has also come to the attention of this headquarters that many young physicians who have completed their internships are not applying for commissions or for acceptance in such residency training programs on the theory that their local boards will either defer them or not process them for induction."

EFFECT OF RADIATION ON GENETICS

A 20-man study group on the effect of radiation on human genetics has made a report to the World Health Organization, portions of which were made public in Washington by the Pan American Sanitary Bureau. WHO organized the study group as part of its program in the field of public health aspects of peaceful uses of atomic energy. Study group chairman was Dr. Alexander Hollander, biological director of Oak Ridge National Laboratory. Another group earlier this year studied radiological units and radiological protection.

The Hollander committee noted that in recent years great advances had been made in the study of heredity and that experience with living creatures ranging from micro-organisms to mammals confirmed the previous observations that mutations are induced by radiation. The bureau added that the group found "strong grounds for believing these genetic effects to be cumulative so that in the long run a small amount of radiation received by each of a large number of individuals could do an appreciable amount of damage to later generations."

A question to which the group devoted close attention was the need for accurate measurement and recording of exposures to radiation, in order to provide background information needed for analyzing the genetic effects. The group learned that in one hospital where such recordings were started there had been a 30% reduction in the total exposure of the staff, and also some reduction in exposure of patients.

PERSONNEL

Dr. Robert Leslie Smith, deputy director of the health office of the Federal Civil Defense Administration, has been assigned to the FCDA's Washington office. Dr. John M. Whitney, health office director, said Dr. Smith will seek to strengthen the civil defense health services through colser working relationships with professional health organizations, the Department of Defense, and other federal agencies. . . . HEW has named Miss Cecile Hillyer chief of the division of training in the Office of Vocational Rehabilitation. Miss Hillyer will supervise efforts to fill serious shortages of professionally skilled persons needed to expand and improve the state-federal program of vocational rehabilitation. . . . Brig. Gen. M. Samuel White, M. C., U. S. A. F., has been assigned to the Office of the Surgeon General as director of staffing and education. He replaces Brig. Gen. Otis O. Benson, who has become commandant of the School of Aviation Medicine, San Antonio, Texas. General White's last assignment was as the air surgeon of the Tactical Air Force.

MISCELLANY

One of the first x-ray tubes used by Wilhelm Konrad Roentgen has been placed on permanent exhibition at the U. S. National Museum, Smithsonian Institution. The tube was purchased from a private owner in Germany and presented to the Smithsonian Institution by the General Electric Company's x-ray department of Milwaukee. . . . The Atomic Energy Commission has reduced its prices for two radioisotopes that are used widely in the field of biology and medicine. New prices became effective July 1 for carbon-14 and iodine-131. . . . The latest volume in the Army Medical Service clinical series tells the story of abdominal surgery performed in forward Army medical units and of the resuscitation of men severely wounded in battle. The volume, "General Surgery," is based primarily upon clinical cases handled and follow-up studies made by members of the second auxiliary surgical group in the Mediterranean Theater in World War II and is the second of two volumes on this subject in the clinical series.

USE OF POLIOMYELITIS VACCINE UNDER EPIDEMIC CONDITIONS

REPORT OF OUTBREAK OF POLIOMYELITIS AMONG NAVAL PERSONNEL AND DEPENDENTS IN HAWAII

Capt. Robert S. Poos (MC), U. S. Navy
and
Neal Nathanson, M.D., Atlanta, Ga.

• *A program of vaccination against poliomyelitis was undertaken among 7,760 Navy families in Hawaii because there was reason to fear that an outbreak, until then concentrated in a single Navy housing area, might spread. The vaccinations were limited to married Navy personnel and their dependents and began Oct. 5, 1955. Epidemiological observations made during the epidemic showed that military and civilian nurseries were important in spreading poliomyelitis among preschool children, from whom the infection spread to their parents, older children, and other adults. After the mass vaccination program, attack rates were lower in vaccinees than in the unvaccinated population, although this difference was not statistically significant. Epidemiological and clinical data did not reveal any evidence of a provoking effect due to injections of poliomyelitis vaccine.*

An emergency poliomyelitis vaccination program was started in October, 1955, during a poliomyelitis epidemic among U. S. Navy personnel and their dependents in Hawaii. (Throughout this report, "Navy" refers to both U. S. Navy and U. S. Marine Corps.) This paper presents some of the observations made during the epidemic and is the first reported study of the mass vaccination of a population in which poliomyelitis was occurring at an epidemic rate.

Previous reports have shown that a formalinized virus vaccine is effective in the prevention of paralytic poliomyelitis.[1] However, these reports were limited to evaluations of the use of poliomyelitis vaccine during periods of relatively low incidence of the disease. There has been considerable discussion and some difference of opinion about the possible danger of the use of the vaccine when the incidence of poliomyelitis is high. The ability of the immunizing injections of diphtheria, pertussis, and tetanus antigens to provoke paralytic poliomyelitis was first reported in 1950 and has been repeatedly confirmed.[2] These reports have shown, with one exception, that provocation is associated with injections given within one month of onset of paralysis and that paralysis frequently involves the inoculated extremity. The provoking phenomenon has also been produced experimentally in monkeys by Bodian.[3] Therefore, there has been concern that injections of poliomyelitis vaccine during the "polio season" or at a time of high incidence of the disease might show a similar ability to provoke paralysis.

This problem was considered by the vaccine advisory committee of the National Foundation for Infantile Paralysis, by special consultants, and by representatives of certain professional groups at a meeting on June 18, 1955. The organizations represented included the American Medical Association, the American Academy of Pediatrics, the American Academy of General Practice, the American Public Health Association, the Association of State and Territorial Health Officers, and the U. S. Public Health Service. The unanimous opinion of the group[4] was that "the total preventive effect of the vaccine in a period of rising poliomyelitis incidence should be much greater than the possible hazard from the provoking effect of the injection." Those present also concluded that "the benefit to be gained by poliomyelitis immunization, in contrast to the small potential risk of provocation, increases in proportion to the severity of the poliomyelitis incidence, since a larger number of paralytic cases should be prevented during the entire period of the epidemic." Those concerned were confident that the severity of the Pearl Harbor epidemic could be modified, and the decision to carry out the Navy vaccination program was made with the knowledge that there was a small potential risk of provocation. An examination of all aspects of the present experience that relate to the provoking effect is made in a later section of this report.

From the U. S. Navy Preventive Medicine Unit No. 6, U. S. Naval Base, Pearl Harbor, Territory of Hawaii (Captain Poos), and the Communicable Disease Center, Public Health Service, U. S. Department of Health, Education, and Welfare (Dr. Nathanson).

Read before the Section on Preventive and Industrial Medicine and Public Health at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

Epidemiological Background

An estimated 43,660 Navy personnel and their dependents reside within Honolulu County. This population is composed of 16,500 single personnel, 7,760 married personnel, 7,760 dependent wives, and 11,640 dependent children. Approximately 90% of the married adults are in the 20-40 year age group. There are numerous opportunities for the introduction of an infectious disease into this resident population. Throughout the year, many thousands of Navy personnel aboard ships are in the area for a few days or weeks. Also, many Navy families in transit between the United States and Pacific stations visit Hawaii for a few hours or days. Since the usual tour of duty in this naval district is two years, about half of the resident Navy population leaves each year and is replaced by new arrivals. The monthly rate of arrival and departure varies with the season, rising to about 6% in the summer and falling to about 3% during the remainder of the year. In addition, although the majority of families live in Navy housing areas, they actively participate in all phases of civilian community life. Finally, and most important, is the fact that frequent and intimate contacts between civilian and military children of preschool age occur in civilian day nurseries, several of which are in constant use by Navy families in the Pearl Harbor area.

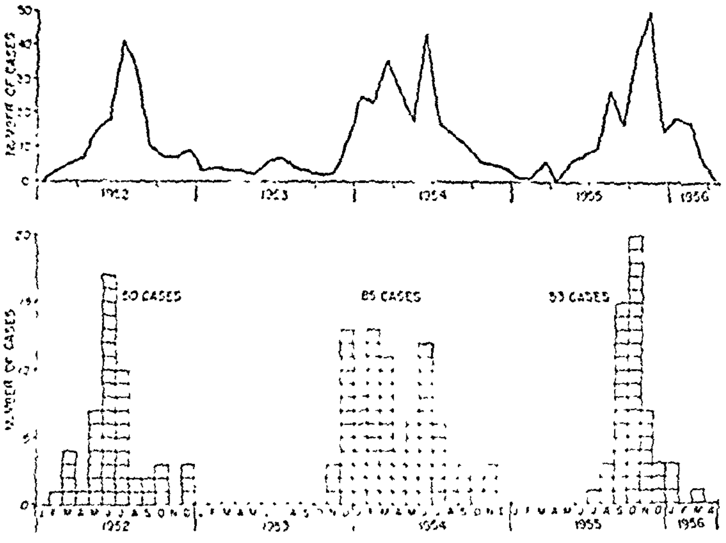

Fig. 1.—Total reported cases of poliomyelitis in Hawaii from 1952 to 1956 (top) and cases among Navy personnel and dependents (bottom).

Many opportunities are available for the spread of infectious disease after introduction into the resident Navy population. Approximately 80% of the families live in Navy housing areas, where the active social life ensures frequent household contact between members of different family units. In each family there are, on the average, between one and two children, and in about 50% of the families there are infants or children of preschool age. An important source of intimate contact for these infants and preschool children is provided by the unofficial Navy nurseries and care centers operated as a community service for Navy families six days and three evenings weekly. Some Navy dependent children spend time in both civilian and military nurseries. All of these nurseries continued normal operations during the epidemic except the largest (Pearl Harbor Nursery), which was closed on Oct. 6, 1955. When this nursery was reopened two months later, admission was restricted to children who had received two poliomyelitis vaccinations. The resident Navy population is an excellent one for the epidemiological study of disease. Military medical care is available for personnel and dependents, both in Navy dispensaries and in the Tripler Army Hospital. Thus, the great majority of illnesses in the population are observed, treated, and recorded in these medical facilities. Detailed clinical records are kept on all individuals receiving medical care, and special records were made on all participants in the vaccination program.

During the past six years, three distinct outbreaks of poliomyelitis have occurred in Hawaii. These outbreaks are shown in figure 1, which presents the monthly incidence reported for Hawaii (taken from the Morbidity and Mortality Weekly Reports of the National Office of Vital Statistics) and monthly totals of cases among Navy personnel and dependents (taken from records of Preventive Medicine Unit No. 6 and the Tripler Army Hospital). Data from these sources are not strictly comparable, since total cases are tabulated by date of report, while cases among Navy personnel and dependents are tabulated by date of onset. It is apparent that during each outbreak of poliomyelitis in Hawaii a simultaneous outbreak occurred among Navy personnel and dependents. This suggests that poliomyelitis infections are spread between the civilian community and the Navy population. Records of the Territorial Department of Public Health show that since 1948 the incidence of poliomyelitis among military dependents residing in Hawaii has been considerably higher than in the local civilian population. The occurrence of poliomyelitis in Hawaii prior to 1953 has been reviewed by Enright.[5]

In a review of case records from the 1953-1954 epidemic among Navy personnel and their dependents, some significant observations were made. Of the total group of 85 cases with onsets in 1953 and 1954, 40 occurred in dependent children, 41 in married personnel and wives, and only 4 in single personnel. Moreover, of the 41 cases occurring among married adults, 36 (88%) involved families with one or more children under 5 years of age, although only about half of all families had children in this age group. These observations formed the basis of the decision to include married adults as well as children in the 1955 poliomyelitis vaccination program.

The 1955-1956 Epidemic

An outbreak of 53 cases of poliomyelitis, with two deaths, occurred between July 29, 1955, and March 2, 1956, among Navy personnel and dependents residing in Honolulu County on the island of Oahu, Territory of Hawaii. These cases, occurring in a population of 43,660, represented an attack rate of 121 per 100,000. The chronological development of the epidemic is presented in table 1 and figure 2. The 23 cases designated in figure 2 by a solid circle will be discussed in a later section dealing with vaccine effectiveness. Of the total of 53 cases, 2 had onset in the 30-day period ending Aug. 5, and 4 in the period ending Sept. 4, with a rapid rise to 13 cases in the period ending Oct. 4, and 24 cases in the period ending Nov. 3. In the next 30-

day period, ending Dec. 3, there was an abrupt drop to four cases, with only six scattered cases during the subsequent three months. Vaccinations were started on Oct. 5, so that the drop from 24 to 4 cases occurred about one month after initiation of the vaccination program. Of the total of 53 cases, 30 (57%) were paralytic. Paralytic and nonparalytic cases ran a parallel time course, both reaching a maximum in October.

† With one death.

Figure 3 is a map of Honolulu County (island of Oahu) with the 53 cases shown according to residence of patient at time of onset. In the Pearl Harbor area there is a central concentration of housing (Navy housing areas 1, 2, and 3, Makalapa, Moanalua, and shipyard), with two additional housing areas (Pearl City and Radford Terrace) at some distance from the central group. About 40% of Navy families live outside the Pearl Harbor area, in the city of Honolulu, Kaneohe, Barber's Point, Nanakuli, and other sections not shown. Sixteen of the first 18 cases were among residents of the Pearl Harbor area. Eleven of the 16 cases in the Pearl Harbor area occurred in 530 officers' families residing in Navy housing area 1. The total attack rate from Aug. 26 to Sept. 30 for the resident population of Navy housing area 1 was 591 per 100,000.

Fig. 3.—Distribution of cases of poliomyelitis.

Of the 11 patients from Navy housing area 1, 10 had a history of close contact with infants who had recently spent time in the Pearl Harbor Nursery. An intensive epidemiological study of the spread of poliomyelitis infection in a nursery school and to occupants of an apartment has been reported.[6] Although there were no recognized cases in Navy housing area 1 after Sept. 30, new cases developed later in adjacent housing areas, as shown in figure 3. This figure shows that 43 of the 53 cases during the epidemic were among residents of the Pearl Harbor area.

The character of the epidemic is further described in table 2, which presents paralytic and nonparalytic cases by age and marital status of the patients and shows the populations from which they were drawn. All patients classified as having nonparalytic poliomyelitis were hospitalized, and the diagnosis was established after careful observation and only if the patient had systemic symptoms, meningeal signs, and cerebrospinal fluid lymphocytosis. Among children, the highest attack rates were in the 0-4 age group, with progressively lower rates for ages 5-9 and 10-14. Among married adults, the rates were higher for ages 20-29 than for ages 30-39. It is striking that rates among

Total	295	159	110	...	391	264	68	...	30	121

married adults were over four times greater than rates among single adults. This difference, significant at the 0.002 level, is discussed below. (See the monograph by Francis and co-workers[1a] for a review of the statistical methods used to compare rates.)

A further analysis of rates among married adults is presented in table 3. Cases in males and females and total populations are broken down according to ages of children in the family, with a further analysis of females according to pregnancy status. A factorial analysis is also presented. This analysis shows that (1) regardless of sex or pregnancy status, parents of children aged 6 months to 3 years had a significantly higher rate than married adults without children in this age group; (2) among dependent wives with children aged 6 months to 3 years, rates were significantly higher for pregnant than for nonpregnant women; and (3) among parents of children aged 6 months to 3 years there was no significant difference between rates for husbands and wives. Thus, it appears that the significant difference in rates among married compared to single adults is due to the very high rates in parents of children 6 months to 3 years and in pregnant women. As a corollary, the rate for married adults without children (37 per 100,000) is very close to that for single adults (30 per 100,000).

In each of the five cases among single Navy personnel there was a history of close contact, 10 to 15 days prior to onset of illness, with preschool-age children while visiting in the homes of Navy families in the Pearl Harbor area. Since relatively few single personnel have occasion to visit Navy families, these observations suggest that those adult patients with poliomyelitis who were not themselves parents of young children may have developed poliomyelitis through contact with young children having inapparent infections.

Prophylaxis Programs

Gamma Globulin.—By Sept. 15, a total of nine cases among Navy personnel and dependents had been reported. Of these nine cases, four had occurred during September among residents of Navy housing area 1. At this time, an urgent request for gamma globulin was made because of fear of an impending epidemic in this housing area. By Sept. 25, when the gamma globulin prophylaxis program was started, five additional cases had occurred among residents of the area. Between Sept. 25 and 28, a total of 1,518 of the 1,830 adults and children in the area were given gamma globulin (0.2 cc. per pound of body weight, with a maximum dose of 30 cc.). Subsequently, two cases occurred among recipients of gamma globulin, one nonparalytic case in a patient who developed symptoms three days after receiving gamma globulin, and one paralytic case in a patient who on hospitalization gave a history of mild symptoms occurring three days prior to receiving gamma globulin.

Vaccination.—By the end of September, there was serious concern that the outbreak of poliomyelitis, concentrated mainly in Navy housing area 1, might spread with equal severity to the 4,120 families in adjacent Navy housing areas. On the recommendation of the preventive medicine officer, an emergency request for poliomyelitis vaccine was made to the surgeon general, U. S. Navy, on Sept. 27, 1955. In response to this request, a special allotment of the supply of vaccine allocated to the Navy under the federal interstate distribution plan was provided for use in Hawaii. This allotment was supplemented by a supply of vaccine originally designated for first and second-grade school clinics but found to be in excess of demand, which was made available through the cooperation of the Territory of Hawaii Board of Health and the National Foundation for Infantile Paralysis.

With special effort directed to stimulation of maximum voluntary participation, the emergency poliomyelitis vaccination program for all married personnel and dependents was started on Oct. 5, 1955. In notices, information bulletins, and at a press conference, the important features of the Navy vaccination program were outlined. Special emphasis was put on the fact that the program was being started at a critical time, when new cases were becoming more frequent. At the time of vaccination, a record was prepared for each vaccinee. The following data were recorded: name, age, family status, address, lot number of the vaccine used, the arm inoculated, and the date of vaccination. Those who reported symptoms of minor illness, especially fever, sore throat, or gastrointestinal upset, or who gave a history of contact with a patient with poliomyelitis were not vaccinated but advised to return later for vaccination. During the first 15 days of the program, approximately two-thirds of the estimated 27,160 married personnel and dependents received a first intramuscular inoculation of 1 cc. of poliomyelitis vaccine, and by Nov. 18, 1955, 45 days after start of vaccination, about 80% of the married personnel and their dependents had received first inoculations (fig. 4). Second inoculations were started on Oct. 26, 1955, and, by Dec. 3, over three-fourths of the vaccinated group had received a second inoculation.

* Single personnel excluded

† NV, not vaccinated; V, vaccinated Data refer to first inoculations only In period Oct 26 through Dec 3, most vaccinees received a second inoculation, so that majority of vaccinated individuals in study from Dec 4 through Jan 2 had received two inoculations

Poliomyelitis surveillance forms were completed on vaccinated patients who developed poliomyelitis. Blood and stool specimens were collected from a number of these patients and their contacts and forwarded to the virus and rickettsia laboratory, California State Health Department. This laboratory reported that type 1 poliomyelitis virus was isolated in tissue culture of the stool specimens of five patients and four contacts.

The vaccination program was limited to married Navy personnel and their dependents. Single Navy personnel were not included, because, as mentioned above, an analysis of the epidemic of 1953-1954 had shown that 41 of 45 cases in adults occurred in married personnel and wives. This decision was justified by the 1955-1956 experience, when 29 cases occurred in adults of whom 24 were married personnel and wives. The five cases among single personnel (all unvaccinated) and the population from which they are drawn are not considered in the remainder of this report, which is devoted to a description and analysis of the vaccination program.

Careful tabulations were made to follow the vaccination program throughout the 90-day study period from Oct. 5, 1955, through Jan. 2, 1956. The study group included all married Navy personnel and dependents resident on Oct. 5, 1955, with the exception of the population of Navy housing area 1, most of whom had received gamma globulin. Also excluded were 201 children inoculated prior to Oct. 5, 1955. The study population was divided into adults and children, and the computations described below were carried out separately on these two subgroups. The total number of Navy personnel on active duty and their dependents resident in Hawaii during the period of the epidemic was available. Housing-office records indicated that an average Navy family had 1.5 children. Using this factor, it was possible to calculate the population of married adults and children resident at the beginning of the vaccination program. This factor was later verified by an accurate census of a representative housing area. The total population was then corrected by subtraction of the population of Navy housing area 1 and adjusted for attrition due to departures. In this way, the study population was estimated for each day from Oct. 5, 1955, through Jan. 2, 1956.

From the vaccination record cards, cumulative numbers of first inoculations were tabulated by individual days, and all nonvaccinees were transferred to the vaccinated group on the day of first inoculation. The following adjustments were then made: 1. Residents of Navy housing area 1 were subtracted, according to date of first inoculation. 2. New arrivals taking up residence after Oct. 5, 1955, were excluded. 3. A correction was made for attrition of the vaccinated population. These adjusted data gave the total number of vaccinees at risk for each day of the study. The unvaccinated population was then calculated on a daily basis by subtraction of vaccinees from the total population. For both vaccinated and nonvaccinated populations, daily totals were grouped to show the number of person-days of risk during successive 15-day periods, beginning Oct. 5, the first day of the vaccination program. These data appear in table 4. This table also shows person-days of risk for the first 30 days of the study period and for the whole study period. These totals are used to calculate some of the attack rates discussed below.

‡ Vaccinated one day after onset of symptoms

§ Includes one patient receiving two inoculations; all other vaccinated patients received a single inoculation

‖ Patients with onset of illness Oct 5 through Jan 2 who were excluded from the study because they arrived in Hawaii after Oct 5 are noted in parentheses

¶ After Nov 18 essentially all first vaccinations were given to new residents who had arrived after Oct 5

Evaluation of Effectiveness

Table 5 presents cases of poliomyelitis among vaccinated and unvaccinated adults and children by paralytic status and date of onset. As mentioned above, the five cases among single personnel are excluded.

This leaves a group of 48 cases, of which 18 had onset prior to Oct. 5, 4 had onset after Jan. 2, and 26 had onset during the study period (Oct. 5 through Jan. 2). Of the 26 patients, 3 are excluded because they arrived in Hawaii after Oct. 5. The remaining group of 23 patients (indicated by solid circles in figure 2) corresponds to the study population described in the previous section. Evaluation of the vaccine is based on study of these 23 patients, of whom 9 were unvaccinated and 14 vaccinated. Of the 14 vaccinated patients, 2 had received two inoculations prior to onset, 11 had received one inoculation prior to onset, and one had received a single inoculation one day after onset of mild prodromal symptoms.

Table 6 presents an evaluation of vaccine effectiveness. This table considers the 23 cases defined above, and rates are calculated on the total number of vaccinated and unvaccinated person-days of risk for the 90-day study period. With the exception of nonparalytic cases among adults, rates among vaccinees are consistently lower than rates among nonvaccinees. However, none of these differences are statistically significant. As noted above, estimates of vaccine effectiveness have appeared in previous reports.[1]

‡ Limited to patients among the resident population on Oct. 5 and whose disease started in the period Oct. 5, 1955, through Jan. 2, 1956.
§ Rates per 100,000 person-days of risk.

Of the 14 patients in the study group who had been vaccinated, 13 had onset of their disease within 30 days of first vaccination, 7 had onset within 14 days of first vaccination, and one later reported the occurrence of mild symptoms one day before first vaccination. In addition, of these 14 vaccinated patients, 12 had received only one inoculation prior to onset. From the clinical data available, a comparison of the severity of cases in vaccinated and nonvaccinated persons can be made. Of the total group of 17 vaccinated persons, 9 had paralytic diseases, and, of these 9, only 2 (22%) required a tracheotomy and respiratory aid. One of these two patients had been vaccinated only one day before onset. By contrast, of the total group of 36 unvaccinated patients, 21 had paralytic disease, and, of these 21, 8 (38%) required respiratory aid and a tracheotomy.

Evaluation of the Provoking Effect

It has already been noted that the severe outbreak of poliomyelitis in Navy housing area 1 ended just prior to the initiation of the vaccination program. If the 11 cases from this area and the 5 cases among single personnel (not eligible for vaccination) are excluded, a group of 37 cases remains. In figure 4, these cases are presented by date of onset. This figure shows that the incidence of poliomyelitis was rising rapidly in this segment of the population during the 15-day period from Oct. 5 through Oct. 19, when almost 75% of this group received a first inoculation. Thus, the circumstances in which the vaccine was used were particularly favorable for the demonstration of a provoking effect. Since a provoking effect should be most marked shortly after vaccination, a comparison is made of cases occurring in vaccinated and unvaccinated persons during the first 30 days of the program. During this period there were 13 cases (7 paralytic and 6 nonparalytic) among vaccinees and 8 cases (4 paralytic and 4 nonparalytic) among nonvaccinated individuals. This similarity in the percentage of paralytic cases among vaccinated and unvaccinated groups does not suggest a provoking effect.

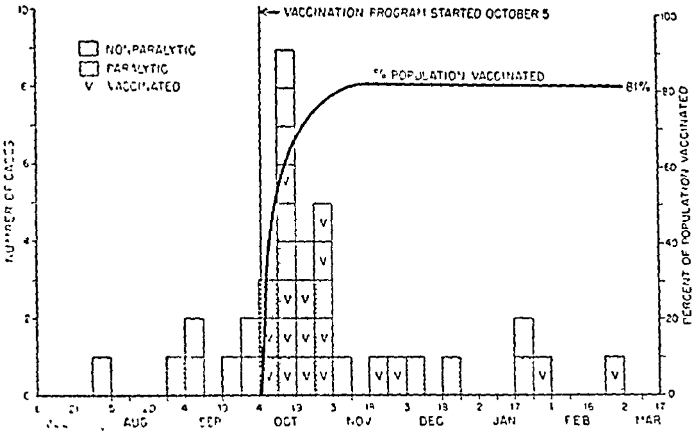

Fig. 4—Poliomyelitis among married Navy personnel and dependents in relation to vaccination program. Navy housing area 1 is excluded.

A comparison of case rates in vaccinated and nonvaccinated persons can also be made for this 30-day period (table 7), with the number of person-days of of risk taken from table 4 and the cases from table 5. In the calculation of these rates, only 12 of the 13 cases in vaccinees are considered, since one vaccinated patient was not in residence on Oct. 5 and was therefore excluded from the study population. No difference between attack rates for vaccinated and unvaccinated individuals was observed. These data suggest that vaccinees did not show any increased susceptibility to clinical poliomyelitis in the first 30 days after initiation of the vaccination program. Another approach to the search for a provoking effect can be made through an analysis of the family rosters that were completed on all patients with poliomyelitis as part of the epidemiological investigation of the outbreak. The 48 cases occurring among married Navy personnel and dependents involved 46 families (2 double-case families and 44 single-case families). There were among these 46 families a total of 135 adults and children who were contacts of an index patient. Of these 135 contacts, 51

Table 7.—*Case Rates During First Thirty Days of Program*

Vaccination Status	Person-Days	Cases	Rate
Vaccinated	446,982	12	2.68
Not vaccinated	298,795	8	2.68

were vaccinated and 84 unvaccinated. Since the majority of vaccinated contacts had received a first inoculation within 30 days of exposure to the index patient, a provoking effect, if present, would have resulted in a higher paralytic attack rate among vaccinated than among unvaccinated contacts. Observed attack rates were similar in the two groups, since one paralytic case occurred among the 84 unvaccinated contacts and one nonparalytic case among the 51 vaccinated contacts.

Although the above epidemiological analysis does not suggest a provoking effect, it is important to look at the clinical character of the total group of cases in vaccinated persons. This is done in tables 8 and 9. In table 8, the vaccinated patients are presented according to paralytic status and interval from inoculation to first symptoms. Of the 17 vaccinated patients, 9 (53%) had paralytic disease. By comparison, of the 36 nonvaccinated patients, 21 (58%) had paralytic disease. Again, there is no evidence that injections of poliomyelitis vaccine provoked paralysis. Of the nine paralytic cases in vaccinees, one was bulbar, one was bulbospinal, and seven were spinal. Of the eight patients with spinal lesions, five showed involvement of legs only, two developed quadriplegia, and one (bulbospinal) was first noted during convalescence to have minimal involvement of the uninoculated arm. This distribution is similar to the distribution of paralysis among patients with naturally occurring poliomyelitis. In particular, there is no preponderance of patients with arm involvement. This is of importance, since all vaccinees were inoculated in the arm, and a provoking effect, if present, would have increased the frequency of arm involvement. Table 8 also shows the intervals from inoculation to first symptoms for the 17 vaccinated patients. When one case where there was history of onset before inoculation and 2 cases where there was an interval of over 30 days are eliminated, 14 cases with intervals of 0 to 28 days remain. When these cases are grouped by seven-day periods, it is seen that in successive periods there were four, four, three, and three cases, respectively, giving no suggestion of a provoking effect.

Table 8.—*Cases Among Vaccinees by Paralytic Status and Interval from Inoculation to First Symptoms*

* Data from Langmuir and co-workers.[16] Two cases in which site of inoculation was not known are excluded from lower section of table.

† Data from Bodian.[3] Fifteen cases in which exact date of first paralysis was not known are excluded from upper section of table.

‡ Includes one patient inoculated twice and classified by interval from second inoculation to onset of paralysis.

Data on inoculation poliomyelitis in man are taken from a report by Langmuir and co-workers[16] on 61 cases of paralytic poliomyelitis occurring among individuals inoculated with residual viable virus in poliomyelitis vaccine prepared by Cutter Laboratories. Data on provoked poliomyelitis are taken from a report by Bodian[3] on 248 Cynomolgus monkeys given 100 to 1,000 TCID$_{50}$ of virulent Mahoney virus by the intracardiac route, with provocation induced by introduction of a needle into the right calf, with or without inoculation of various irritating materials. In both inoculation polyiomyelitis and provoked poliomyelitis, the majority of resulting paralytic cases developed with first paralysis in the inoculated extremity at an interval of 4 to 14 days after inoculation. Of the nine vaccinated Navy personnel and their dependents with paralytic cases, only three had onset of paralysis 4 to 14 days after inoculation, and none developed initial paralysis in the inoculated extremity. In neither respect is there any suggestion of a resemblance to inoculation poliomyelitis or provoked poliomyelitis.

Evaluation of the provoking effect is completed by an analysis of the relationship between the site of inoculation and extent of final paralysis. Of the nine vaccinated patients who developed paralytic disease, eight were inoculated within 30 days of onset. During the illness of these eight patients, paralytic poliomyelitis developed in two of the eight inoculated arms and in three of the eight uninoculated arms. Thus, prior inoculation of an extremity did not increase the frequency of paralytic involvement of that extremity. This finding is in sharp contrast to studies of the provoking effect of certain other immunizing injections.[2]

Summary and Conclusions

As the result of epidemiological observations on outbreaks of poliomyelitis occurring between 1953 and

1956 among Navy personnel and dependents in Hawaii and of experience with a voluntary mass vaccination program started during the 1955 epidemic, certain tentative conclusions can be drawn: 1. Military and civilian nurseries are important in the spread of poliomyelitis infections among Navy infants and children of preschool age, who subsequently may infect their parents, older children, and other adults. 2. Among the total group of adults, attack rates were significantly higher in parents of children aged 6 months to 3 years than in single personnel or in married adults without children in this age group. On review of a previous epidemic among Navy personnel and dependents in Hawaii, similar observations were made. Among dependent wives with children aged 6 months to 3 years, rates were significantly higher in pregnant than in nonpregnant women, while no significant difference was observed between rates in husbands and nonpregnant wives. 3. After the mass vaccination program, attack rates were lower in vaccinees than in the unvaccinated population, although this difference was not statistically significant. 4. Epidemiological and clinical data did not reveal any evidence of a provoking effect due to injections of poliomyelitis vaccine. 5. Further studies on the use of poliomyelitis vaccine under epidemic conditions will be necessary if the tentative conclusions of this study are to be firmly established.

NEWER DRUGS IN THE TREATMENT OF HYPERTENSION

EXPERIENCE WITH RAUWOLFIA DRUGS AND PROTOVERATRINE

James E. Gibbons, M.D., John C. Muller, M.D., William W. Pryor, M.D.
and
Edward S. Orgain, M.D., Durham, N.C.

• *The effects of certain preparations of Rauwolfia were studied in 58 patients who had hypertension in various degrees of severity. The doses, initially small, were gradually increased until a fall of blood pressure or unpleasant symptoms occurred and were reduced when troublesome side-effects appeared. In the 58 patients so treated, the group fall in mean blood pressure amounted to 12 and 15 mm. Hg for the recumbent and the standing positions respectively. Minor side-effects were observed in 48 and severe mental illness in 4 of the patients. In 19 patients the addition of a Veratrum preparation to the therapy caused further reductions of only 2 and 3 mm. Hg for recumbent and standing blood pressures, although the dosage was large enough to cause alarming symptoms in two. In seven patients who received Veratrum preparations alone, no consistent hypotensive response was obtained. The need of watchfulness and of individual adjustment of dosages was clearly demonstrated.*

New drugs, utilized alone or in various combinations, are currently employed with increasing enthusiasm in the treatment of hypertensive vascular disease. The most useful drug or the most effective combination for all hypertensive patients remains unsettled, due principally to lack of satisfactory hypotensive effect or to disagreeable and even hazardous reactions from the drugs. It therefore seemed worthwhile, in one of a series of studies on hypotensive agents, to investigate the efficacy of several Rauwolfia drugs and protoveratrine when administered alone and in combination.

The mild hypotensive effect of Rauwolfia serpentina, first described by Indian workers in 1931, is attributed to peripheral vasodilatation from central inhibition of the sympathetic nervous system and possibly a direct action on the vessel wall.[1] Introduced into this country by Wilkins[2] in 1952, preparations now available include the crude root of Rauwolfia serpentina, a semipurified alseroxylon fraction, and the pure alkaloid, reserpine. Several reports attest to their hypotensive action and their principal usefulness in mild hypertensive vascular disease.[3] The simplicity of oral administration and the desirable tranquilizing effects have led to their widespread acceptance by the medical profession. The production of serious mental illness has only recently been stressed.[4]

From the Department of Medicine, Duke University School of Medicine, and the Cardiovascular Service, Duke Hospital.

Several biologically standardized preparations of Veratrum viride and Veratrum album are available, including the pure alkaloids, protoveratrines A and B. These compounds, presumed to act by reflex parasympathetic stimulation,[5] have been recommended particularly to enhance the hypotensive effects of Rauwolfia drugs and hydralazine.[6] It is the purpose of this paper to report our experience in the treatment of 58 patients with hypertensive vascular disease treated with Rauwolfia compounds and protoveratrine, alone and in combination.

Material and Methods

Previous publications from this hospital[7] have outlined methods of study and follow-up of hypertensive patients. The present series of 58 patients comprises 33 males and 25 females, ranging in age from 22 to 78 years (average 47.7 years), treated with Rauwolfia compounds for periods of from 3 to 14 months (average 6 months). The group average pretreatment blood pressure was 188/112 mm. Hg (mean 137) recumbent, and 175/111 mm. Hg (mean 132) standing. (Mean blood pressure is here defined as the number obtained by adding one-third of the difference between diastolic and systolic pressure to the diastolic pressure.) As outlined by Page[8] and Goodyer,[9] the patients' conditions were graded according to a "severity index" based on the following data: level and duration of blood pressure, changes in the fundi, renal function, and evidences of cerebral vascular disease, cardiac enlargement, heart failure, or coronary disease. Graded in this manner, conditions of 19 patients were classified as grade 1 (mild), of 37 patients grade 2 (moderate), of one patient grade 3 (severe). and of one patient grade 4 (malignant).

Rauwolfia compounds were administered orally two to four times daily in divided doses. Doses used were initially small, then gradually increased until a fall in blood pressure or unpleasant symptoms occurred, and reduced when troublesome side-effects appeared. The final ranges and average daily doses were reserpine (Serpasil), 0.5 to 4.0 mg. (average 1.5 mg.); reserpine (Serpine), 0.6 to 2.4 mg. (average 1.4 mg.); and Rauwolfia (Raudixin), 200 to 750 mg. (average 400 mg.). Both hypotensive reactions and side-effects of the three drugs were approximately comparable.

Protoveratrines A and B (Veralba) or protoveratrine A and B maleates (Provell maleate) were administered in divided doses, beginning with 0.25 mg. three times daily after meals and increasing to 0.75 mg. three times daily; rarely could patients tolerate more than 1 mg. as a single dose, and few could tolerate more than 0.5 mg. given three to four times daily. Maximum tolerated doses were given for periods of from 2 to 10 months (average 4.8 months). In 19 of these 58 patients, protoveratrine was also used after a variable period of Rauwolfia therapy alone. The average recumbent blood pressure for the 19 patients before the addition to therapy of protoveratrine was 197/104 mm. Hg (mean 134).

Results

For the group of 58 patients treated with Rauwolfia compounds alone, the average blood pressure after treatment was 173/101 mm. Hg recumbent (mean 125) and 155/98 mm. Hg standing (mean 117). This group fall in mean blood pressure of 12 mm. Hg recumbent and 15 mm. Hg standing does not reflect accurately the effectiveness of these drugs. In table 1 the patients are grouped on the basis of the pretreatment mean recumbent blood pressure, and here the magnitude of fall in mean recumbent blood pressure for each group is indicated as well as the number of patients whose blood pressures fell to "normal." (Normal is here defined as a mean recumbent blood pressure of 115 mm. Hg or less.) The tabulated data reveal reduction of blood pressure to normal levels in 19 of the 58 patients (33%). Considering only the patients with moderate and severe conditions (groups 2 and 3), 13 of 34 patients (38%) had "definite" blood pressure responses. (A definite response is here arbitrarily defined as a fall in mean recumbent blood pressure of more than 20 mm. Hg.) This result is in agreement with the recent review by Goodyer,[9] who noted that hypotensive effects were observed in 39% of 218 patients treated by five different groups. The "severity index" gradings were altered by the blood pressure responses in that, in 17 of 37 patients, grade 2 (moderate) conditions became grade 1 (mild) conditions, and, in the single patient with a grade 4 (hypertensive) condition, the illness became grade 3. During the period of observation reported, no changes were observed in the major clinical manifestations of hypertensive vascular disease, i. e.. coronary disease, cardiac enlargement, and renal disease. Minor fluctuations in the electrocardiographic tracings and observations of the ocular fundi seemed insignificant and did not further alter the severity index gradings. Our results indicate Rauwolfia compounds to be useful in the more severe forms of hypertension as well as in the mild, labile group.

As reported by others. side-effects from Rauwolfia drugs are common and include nasal stuffiness, weight gain, drowsiness, fatigue, loss of initiative. dreams, nightmares, jitteriness, and occasionally mild diarrhea. Such minor symptoms were observed in 82% of patients but were usually controlled by reduction of dosage. However. four patients (6.9%) from the present group, reported in detail elsewhere,[4] developed severe mental illnesses characterized by anxiety. agitation. and depression. These cases emphasize the importance of large daily doses administered for prolonged periods as well as a history of previous psychiatric illness as probable etiological factors.

In our own cases, the intensity of the eosinophilia paralleled the degree of allergic sensitivity, and there is hardly any doubt it was provoked by an allergic reaction taking place in the tissues. While it is true that the skin is the principal shock organ in allergic contact dermatitis, we have encountered individuals with constitutional reactions that were suggestive of a more generalized state of sensitization than is usually presumed in this form of allergy. There was evidence, for instance, that the muscle could react allergically, giving rise to painful symptoms that disappeared as the patient became hyposensitized by further injections. The possible existence of noncutaneous shock tissues when a contact allergen is given by an abnormal route (intramuscularly) raises a very interesting question, which is at the core of the problem of how the pulmonary infiltrates are formed in eosinophilic pneumonitis. Is the lung a primary shock organ and the infiltrate a consequence of an allergic reaction taking place there, or is there an alternative mechanism? If one reasons according to the custom of finding the simplest formulation to explain all the known data, then we shall set aside the likelihood of a primary hypersensitivity reaction in the lung, for such an explanation does not include the cases of eosinophilic pneumonitis that are of nonallergic origin. There is another explanation that has the further advantage of revealing why allergy is so often associated with the syndrome, though not, in our opinion, directly causative of it.

The eosinophilia, whether allergic or not, is, according to the hypothesis we are proposing, an indispensable and central element in the pathogenesis of the lung lesions. Vaughn's[4] studies are particularly instructive in providing an understanding of how eosinophilia can directly lead to pathological changes in the lung. He experimentally produced eosinophilia in nonsensitive guinea pigs by several different methods and found, by periodic histological study, that the eosinophils concentrated earliest in the lungs, later in the small intestines, and still later in the spleen. Histologically, the lungs showed consolidation, atelectasis, and congestion, with numerous eosinophils in and about the blood vessels and bronchi. These changes might easily have given rise to radiopacities had roentgenographic studies been done. Actually, since eosinophilic pneumonitis is a benign self-resolving disease, practically nothing is known about the histopathological alterations in the lung, save that they are massive enough to be revealed by chest x-rays. Until someone is enterprising enough to perform lung biopsies during the active stages, we will continue to remain ignorant on this score. In our opinion, the findings recorded in a few autopsy studies[5] probably reflect more the chronic changes of the underlying disease, usually asthma, or are open to criticism on the question of diagnosis.

Surveying the available clinical and pathological evidences, we might reconstruct the pathogenesis of eosinophilic pneumonitis as follows: The initial event is an eosinophilia, often allergic (such as asthma, intestinal parasitism, or drug allergy), but sometimes of other cause. Incidentally, it is altogether inadmissible to regard every drug reaction as allergic; the popular habit of blaming allergy for every exotic or otherwise inexplicable response is scientifically contemptible and productive of the greatest confusions. The eosinophilia provoked by drugs may have nothing to do with allergy; accordingly, when eosinophilic pneumonitis follows the administration of a drug, it is obligatory that the observer prove the allegation of allergy. In our own cases, we administered an agent to which the subjects were known to be hypersensitive and, indeed, the eosinophilia was in direct proportion to the degree of clinical hypersensitivity. It is only fair to remark, however, that, when huge amounts of 10% solution of 3-pentadecylcatechol in sesame oil (8 cc.) were given in one week to nonsensitive persons, a moderate eosinophilia up to 15% developed. Either the oil, the 3-pentadecylcatechol, or both, might have been responsible, but normally such an amount would be administered to sensitive persons over a period of months; furthermore, when the routine hyposensitization procedure was followed, the mildly sensitive individuals did not respond with an eosinophilia, which we take to mean that the eosinophilia regularly observed in the highly sensitive persons was truly allergic. Perhaps the oil potentiated the eosinophilogenic property of the allergen (3-pentadecylcatechol).

Regardless of how the eosinophilia comes about, it would seem according to Vaughn's findings[4] that the lungs and, less importantly, other viscera have a tendency to trap or filter out the eosinophils in some unknown way, possibly because eosinophils have an affinity for structures with high histamine reserves, of which the lung is supposed to be one.[6] Corollary evidence is afforded by Bierman and co-workers,[7] who showed a mechanism exists in the lungs for trapping leukocytes, though, unfortunately for our purposes, they did not study eosinophils. In the person destined to develop eosinophilic pneumonitis, this mechanism is overwhelmed—perhaps the eosinophils crowd in in enormous numbers and cannot be disposed of, leading to inflammatory responses. Perhaps similar events are taking place in other tissues, but, in such a transient syndrome, detection would be difficult. In fact, Ampuran[8] in India, who has observed in excess of a thousand cases of eosinophilic pneumonitis in association with intestinal parasitism, affirms that the manifestations are more widespread than commonly appreciated, especially in regard to gastrointestinal symptoms.

We particularly wish, as a result of our own experience, to raise the question of incomplete or abortive forms of eosinophilic pneumonitis. We encountered a number of patients who developed hacking cough and marked eosinophilia whose chest films showed definitely increased hilar markings, interpreted by the radiologist as consistent with the findings in "drug allergy." These symptoms and signs subsequently disappeared, more slowly than in classical eosinophilic pneumonitis, possibly because we continued the routine administration of 3-pentadecylcatechol, thereby maintaining the stimulus to eosinophil production. Following our thesis, we suggest that these cases also represented pulmonary eosinophil-trapping of a lesser degree and should be incorporated into a less rigid concept of eosinophilic pneumonitis. We do not subscribe to the belief that there is any natural relationship between this syndrome and polyarteritis nodosa.

One of our bona fide cases deserves special mention, because, after recovery, we undertook the injections of 3-pentadecylcatechol again until the patient was hyposensitized. The pneumonitis did not recur, even though the eosinophilia persisted.

Summary

Experience with seven cases of eosinophilic pneumonitis (Löffler's syndrome) developing during poison ivy hyposensitization stimulated an appraisal of the mechanism of production of pulmonary infiltrates. Our view is that the infiltrates are due to trapping of eosinophils in the lung and not, as commonly believed, to an allergic pulmonary reaction. Moreover, we hold that abortive forms of this syndrome may exist as drug reactions. These concepts require further experimental verification.

NEW DRUGS AND AN ERA OF ANALGESIA AND AMNESIA

John S. Lundy, M.D., Rochester, Minn.

• *The array of agents now available for anesthesia and analgesia should be exploited to the utmost. Anesthesia starts the evening before an operation, with an interview that helps to decide the entire plan for premedication and subsequent procedures; this plan must be one that leads to the objective more certainly and safely than any other conceivable means. In the evening, the patient generally receives a tranquilizer such as promethazine and a somnifacient such as ethchlorvynol. In the morning, the premedication commonly consists of promethazine, morphine, and atropine. General anesthesia proceeds with thiopental sodium or with a muscle relaxant, oxygen, and nitrous oxide. Dosages must be such as to avoid respiratory difficulties; it is better to allow the patient to breathe for himself. In the postoperative period promethazine is used for its antinauseant effect and for its synergism with analgesic drugs. New drugs useful for producing amnesia, for blocking sensory nerves, and for combating shock are available, and improvements are being made in equipment for monitoring the patient's condition, communicating with other departments, and transporting the patient within the hospital.*

Today, as it has ever been since the time of Adam's rib, we are concerned about the control of pain. For many years we have had the means to control pain, but sometimes this could be done only at the risk of producing untoward results, such as addiction of the patient or even death from overdosage Hence, even though the conquest of pain had been largely achieved, problems of great magnitude remained We need have no hesitation in acknowledging the fact that impressive contributions to the solutions of these problems were made in the laboratories of pharmaceutical companies.

Caution an Indispensable Ingredient

In fact, progress has been such that we now rarely hear it said that physicians generally are kept up-to-date mainly through the detail man of the pharmaceutical house. Once this was so to some degree, now it is not. What has happened, rather, is that the pharmaceutical houses have established themselves as important contributors to medical practice Almost uniformly they give exhaustive consideration to the factor of safety before they allow a preparation to reach the market.

One of the outstanding examples of such caution was provided by Dr. J. F Biehn, of the Abbott Laboratories, in the work that was done with thiopental (*Pentothal*) sodium before it was marketed. The product was not permitted to be sold until Dr. Biehn was satisfied as to its clinical application. More than two years elapsed before the agent reached the market, but the soundness of his decision is reflected in the success this drug has enjoyed over all the world.

Actually, I am glad to make this tribute to the pharmaceutical industry, because I have been impressed on many occasions with the contributions of that important field of endeavor to medical practice, particularly in my own field. I have also observed, on the other hand, that, when this paramount principle of caution has not been followed by a pharmaceutical maker, the confusion that results sometimes is associated with needless morbidity and even death. I therefore urge that even greater caution be exercised in the investigation of anesthetic drugs. The handling of anesthetics is similar to the handling of firearms—even a little carelessness may result in injury or death

---

Chairman's address, read before the Section on Anesthesiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

Premedication and Anesthesia an Inseparable Duality

Relief of pain during surgical operation or obstetric delivery of course has long been the province of the anesthesiologist and the anesthetist. But this is too simple a reduction of terms. There is infinitely more to relief of pain than the definition of it. I have a very definite idea about the administration of an anesthetic agent, and so I think the entire array of agents available for anesthesia should be exploited to the utmost. For example, I believe that the anesthesiologist who gives the anesthetic should order the preliminary medication and see the patient beforehand. If the operation is to be done in the morning, the anesthesiologist or his representative, who has been trained in his ways and thinks as he does, should see the patient the evening before the operation. At that time anesthesia is started, so far as I am concerned. This means that preliminary medication and the administration of the anesthetic are an inseparable duality. Premedication is prescribed in such a way and in such a dose that the patient reaches the precise stage of tranquility that I wish to exist when he is placed on the operating table. Thenceforward, with minor exceptions, the course of events ought to be almost inevitable: anesthesia should proceed so smoothly that the state of anesthesia at a given moment can be predicted by the clock. This means that the person in charge, like a conscientious airman, previously has filed a flight plan that, when carefully followed, leads to the objective more certainly and more safely than any other conceivable means.

At bedtime the average adult patient will receive from me a dose of 25 mg. of promethazine (Phenergan) by mouth. Of course, chlorpromazine (Thorazine) can be used, and, in addition, 500 mg. of ethchlorvynol (Placidyl), 400 mg. of methyprylon (Noludar, 3,3-diethyl-5-methyl-2, 4-piperidinedione), 1.5 to 3 grains (0.1 to 0.2 gm.) of pentobarbital (Nembutal), or 400 mg. of glutethimide (Doriden, α-ethyl-α-phenyl-glutarimide). The combination of promethazine with one of these other agents usually results in an exceptionally good night of sleep for the patient. Meprobamate (Equanil or Miltown) is a new drug that induces tranquility but has no synergistic effect on any other agent. It can be used in place of promethazine or chlorpromazine, and, if this is done, no change in the technique of anesthesia is required.

On the morning of the operation I like to call on the patient and ask him how he slept, so that I may know how effective the drug was that he received the night before. Usually, for an adult patient, I repeat the dose of 25 mg. of promethazine, giving it intramuscularly, and I administer ⅛ or ⅙ grain (8 or 10 mg.) of morphine and 1/150 grain (0.4 mg.) of atropine. The dose of morphine at this time ought not to be as large as that customarily used, because, even in a good-sized, robust adult patient, the use of ¼ grain (15 mg.) of morphine often will mean that after anesthesia has been induced ventilation may be inadequate or may stop.

Caution in Dosage

When the plan just described has been used, particular care must be exercised in the dose of anesthetic agent employed. For example, when the patient is brought to the operating room, he already has had two doses of promethazine. This increment often makes it possible to reduce the needed amount of an anesthetic agent, such as thiopental sodium, to half the amount usually employed. Hence, if a muscle relaxant such as succinylcholine (Anectine or Quelicin chloride) has been used, nitrous oxide, at the rate of 7 liters per minute, and oxygen, at the rate of 3 liters per minute, will be administered by intubation, so that an arterial oxygen saturation of 100% is obtained. Here trouble may arise: it is a bit difficult, when this arrangement is first put into effect, to avoid administering the anesthetic agents too rapidly and in such a dose that respiratory depression or cessation of respiration develops. Such respiratory difficulties probably are not dangerous, since all anesthesiologists are now familiar with the technique of controlled respiration, which is produced by pressing on the breathing bag. This means that adequate ventilation can be maintained with ease, especially if an intratracheal tube is in place. Yet it is certainly better to allow the patient to breathe for himself. This is particularly important from the standpoint of the pH of the blood. I do not know to what degree marked changes in the pH of the blood could contribute to mortality, but that factor might be a reason why autopsy often does not offer an explanation of the cause of death of an anesthetized patient. When a patient breathes by himself, I feel very much safer about variations in the pH of the blood.

In the postoperative period, promethazine seems to control nausea and vomiting very well, particularly if it is administered along with pain-relieving drugs. Pain-relieving drugs also can be used in less than large doses, and the reduction is desirable. A drug such as promethazine or chlorpromazine, which has a synergistic action on pain-relieving drugs, may cause some of the mild, nonaddicting pain-relieving drugs to suffice in cases in which they have been inadequate previously. For the most part, it has been possible to neutralize the nausea associated with the use of morphine, but the constipating effect persists. Levorphanol (Levo-Dromoran) tartrate in a dose of 2 mg., with promethazine, has been of value in this respect. It is, moreover, particularly effective against posthemorrhoidal pain.

Bright New Spectrum of Anesthetic Agents

Interestingly enough, since promethazine has been used at the Mayo Clinic in preliminary medication for hemorrhoidectomy before sacral block done with either procaine hydrochloride or piperocaine (Metycaine) hydrochloride, only 2 of 300 patients were observed to have nausea and vomiting. One patient vomited once only; the other patient remained nauseated for half an hour but did not vomit. To me such a result is very dramatic, because over the years that I have employed sacral block anesthesia, nausea and vomiting followed it with such inveterate frequency that I always had a tank of oxygen available at the head of the table. The nurse anesthetist could thus administer oxygen from a bag, with a mask attached to it by a length of tubing. A needle valve permitted the oxygen to flow rapidly enough to keep the bag inflated. This device gave much relief to patients who were nauseated and who were inclined to vomit. We almost never use it now.

Ethoheptazine (heptacyclazine, WY-401) is more effective with promethazine than without it. It is a variation of meperidine (Demerol) hydrochloride brought about by the insertion of an extra carbon in the nucleus. Another drug, anileridine (Leritine), which is a variation of meperidine, is more potent in the control of pain than meperidine itself. I feel that, while I cannot condemn the use of meperidine for preliminary medication, I am opposed to its use in the postoperative period for more than a day or two, and I think it should not be used for chronic pain. My reason is that, once the patient shows any tendency toward addiction, withdrawal symptoms follow the short period of relief from pain obtained with meperidine. The insidious sequence is that greater and greater doses are required, until some addicts take as much as 3,000 mg. of the drug per day and reach a point at which convulsions occur.

A very useful drug that is less provocative of addiction is methadone hydrochloride. This generic term is used by some firms. One firm markets it under the name of Dolophine. Methadone often is prescribed for persons addicted to the use of meperidine while meperidine is being withheld from them, because they more easily tolerate the withdrawal of methadone than the withdrawal of meperidine.

A variety of drugs that show real promise have been introduced rather recently. Among these drugs is alphaprodine (Nisentil) hydrochloride. This drug contributes much to the safety of anesthesia. Another new drug, Viadril (21-hydroxy-pregnanedione sodium succinate), is very singular. I have been able to administer it with ordinary preliminary medication without use of promethazine. A dose of 1 cc. of a 1% solution of Viadril per pound of body weight is injected through a large needle (15 gauge) into the vein in the antecubital fossa without a blood-pressure cuff on the arm, but with the forearm elevated, so that the drug runs downhill rapidly. Even so, while the drug is being infused, the patient will complain that he has pain in the arm in which the vein is located. When this occurs I irrigate the vein with a parenterally given fluid such as isotonic solution of sodium chloride or a 5% solution of dextrose in water. The necessity for such action is a deterrent to the use of this agent. However, since it is a steroid made from Mexican yams, with a formula almost identical to that of testosterone, except that Viadril has a succinate group in it, the dosage can be somewhat reduced if promethazine has been given beforehand. Moreover, curare can be used to keep the dose of the drug small, since there is little or no laryngeal spasm when Viadril is employed—an important feature in intubation.

Analgesia and Amnesia

Another new drug that I have used is Dolitrone (5-ethyl-6-phenyl-metathiazane-2,4-dione). This is an agent of considerable promise both in anesthesiology and in any field in which hypnosis and analgesia are important. With a full dose of this drug, usually used intravenously in a 2.5% concentration, satisfactory anesthesia can be produced. Curare can be used with it, because Dolitrone does not produce laryngeal spasm. If half an anesthetic dose is used, analgesia and amnesia are produced, and if half the analgesic dose is administered, amnesia is produced. The amnesic state may not be recognized by either the anesthesiologist or the patient at the moment, but subsequently the patient says he does not remember anything. This would be particularly useful during procedures in the course of which patients should be interrogated.

The amnesic state is extremely useful for patients who dread the induction of local anesthesia or a nerve block. The potentialities seem almost boundless; I have used Dolitrone to advantage particularly in patients who are to have teeth extracted under local anesthesia but who will not tolerate the injection of a local anesthetic and do not wish to remember anything of the extraction. I also have used Dolitrone to advantage in patients who are to undergo sacral block anesthesia and who are completely intolerant to that method. I have used Dolitrone for patients who could not, because of some injury or deformity, assume the position necessary for the operation.

Here, again, however, the native caution of the anesthesiologist must come to the fore. For example, I administered Dolitrone to a patient whose injuries in an automobile accident subsequently prevented her from lying in the so-called Buie position for sacral block anesthesia and hemorrhoidectomy. A small dose of Dolitrone was injected into a vein in the back of the hand. When the patient assumes this position, which resembles the Kraske position, the drug must ascend from the small veins to the large ones. Under such circumstances thrombophlebitis is likely to develop in the vein that is the site of injection. Hence. when either Viadril or Dolitrone is used, this difficulty of irritation of a vein must be overcome. This is a challenge directed peculiarly at the anesthesiologist, for laboratory research may not be conducive to a ready solution. Sometimes it is difficult to produce a lesion in a research laboratory and then deal with it. The thrombophlebitis associated with the use of Dolitrone and Viadril will continue to appear unless we can find some means to counter it prophylactically.

I once administered Dolitrone to a patient sitting in an operating chair who gagged so severely that the surgeon could hardly infiltrate the tonsillar pillars with an anesthetic agent preliminary to tonsillectomy. The surgeon finally gave up and called me, saying, "Do something." The situation was new to me, but I injected 12 cc. of a 2.5% solution of Dolitrone in 12 minutes into a vein in the back of the patient's hand. He remembered the insertion of the needle but nothing more, although he sat up and opened his mouth when asked to do so. He said he could recall no part of the procedure until he was shown the removed tonsils. In this patient the same vein was used that had been employed in the other patient but, interestingly enough, no difficulty ensued. The position of the patient during operation of course was entirely different.

On another occasion the same surgeon asked me to "do something" for a woman who became hysterical during his attempt to operate on her nose. Local anesthesia had been used. I administered 6 cc. of a 2.5% solution of Dolitrone and brought her under control.

Hazards, New and Old

By reducing the dose of the anesthetic agent by means of preliminary medication, we enhance the safety of the patient. However, there are other measures concerning the safety of patients. Surgical patients who have been *given cortisone* previously but are no longer taking it must be prepared for the stress of operation by receiving cortisone two or three days before they are operated on, on the day of operation, and for two or three days after operation. Not all operations are elective, however, and not all patients are prepared properly, and so it is fortunate that we have lyophilized hydrocortisone (Solu-Cortef). An intravenous injection of 100 mg. of this drug dissolved in 2 cc. of water may be given to a patient who is in a *state of neurogenic or surgical* shock. If the response is poor, adrenocortical extract should be used.

I cannot emphasize too strongly the responsibility of the physician to advise his patient that he is receiving cortisone, if this agent is being administered. In the face of an *impending operation*, the patient *is expected to notify a surgeon* that he has received cortisone, but that is not possible unless the patient himself knows what he has received.

It is very helpful indeed to administer lyophilized hydrocortisone to any patient, whether or not he has received cortisone, who does not respond properly to the administration of blood, dextran, parenterally given fluids, or stimulants or a combination of these. What we need badly is some means of marking the soles of the feet, or some other usually covered area, as in a tattoo, to set forth indelibly a patient's blood group and Rh factor so that, in an emergency, the correct blood can be given quickly.

A very important contribution to those of us who employ massive doses of drugs, and particularly narcotic agents, was the development of nalorphine (Nalline, N-allylnormorphine) hydrochloride, a drug that will neutralize the effect of morphine very quickly when given intravenously. However, it does have the disadvantage that, if the patient has taken a large *overdose of, say, a barbiturate* and the nature of the drug is unknown, the use of nalorphine would markedly increase the depression rather than relieve it. This might be regarded as an aid in inverse character, since it might help to establish that the drug the patient had taken was not morphine. Yet, until very recently, we had nothing that would neutralize the nalorphine except morphine, but few of us would have enough courage to administer that drug for such a purpose.

Recently an agent called Lorfan tartrate (3-hydroxy-N-allylmorphinan) has been developed, which is antagonistic to a number of drugs and is without other effect. It has increased the safety with which we can manage patients who, either accidentally or purposely, receive an overdose of these depressant drugs.

Refinements of Older Techniques

Diagnostic and therapeutic block anesthesia is receiving some of the attention it deserves. Papers and books on the subject are appearing more frequently. This situation is gratifying to me, for over the years I have been convinced that more attention needs to be paid to patients who complain chiefly of pain. The first impulse of some is to refer these patients to a psychiatrist, but it is not mine. Rather, I try to find the pathway *of pain with the aid* of nerve-blocking agents, if necessary. I have advocated the use of roentgenograms to identify the place at which the point of a needle lies. I still think that the principle unquestionably is right, but unfortunately it is not generally employed. Surely, if an injection is worth attention at all, it is worth doing well. The roentgenogram is convincing to the neurosurgeon when it suggests that certain nerves be cut, and it makes a fine record, so that if the block needs to be repeated, the needles can again be placed as they were in the first roentgenogram. Subsequent injections probably could be done with accuracy any place in the world, if the original roentgenogram were forwarded to the physician concerned. When sympathetic nerves are to be blocked semipermanently, as they are in an alcohol sympathectomy, then a sweating pattern should be made two or three days after the block has been done. Then, if the effect of the alcohol wears off, another sweating pattern can be made and, if it is seen that the sweating has returned, the block can be repeated. Conversely, if the sweating pattern is unchanged, no advantage will accrue from another block.

Pain associated with a postoperative incision and scar or *even with a tear, such as might occur in the* vault of the vagina when forceps have been used in obstetric delivery, *may be attributable to the nerves* as well as to other parts of the tissues that have been injured. In the healing process the severed nerves occasionally do not rejoin, and, if they do not, multitudes of small neuromas probably have developed. I have had *at least two patients* who suffered pain lateral to a scar in the lower region of the abdomen; by blocking the 11th and 12th thoracic nerves and the first lumbar nerve, I have been able to relieve the pain. Subsequently, the sensory roots of these nerves were severed surgically, and the patients have been free of pain ever since. One patient who had had a tear in the right vault of the vagina during a forceps delivery 10 years previously obtained relief when the second sacral nerve on the right side was blocked; subsequently, this sensory root was severed surgically and since the severance, more than a year ago, she has obtained relief estimated at 85%.

I find that relief should last for some hours to be convincing, and so I have prepared a mixture of a local anesthetic agent. I now use procaine hydrochloride in either a 1, 2, or 3% concentration, plus a 2.5% solution of ammonium sulfate and a 2% solution of benzyl alcohol. With this mixture I obviate those difficulties that can be caused by alcohol, and the relief obtained often lasts much longer than that produced by a plain local anesthetic. A procedure such as this will indicate perhaps either that operation should be done or that alcohol should be used later.

Actually, the use of injections of alcohol demands extreme precision. For instance, the needles must be placed exactly and located by roentgenograms; then

ACC-No-1364

the alcohol is injected, 0.5 cc. at a time, with a momentary pause between the deposit of each 0.5 cc. I have called this the "spot-wetting" technique, and it is most satisfactory when small quantities of alcohol are injected. However, if the quantity is more than sufficient to wet the spot where the tissue is situated, the alcohol may spread to other nerves and result in alcohol neuritis, which is the dread of anyone who does this work.

It is amazing, however, that in some cases the effects of alcohol sympathectomy have lasted for a year or more. Blood supply has been increased in many instances, and the procedure has been helpful in skin grafting and in many instances of the shoulder-arm-hand syndrome in which physical therapy would have been impossible unless the block had been done.

Recently, I injected alcohol into a patient for neuralgia of the left superior laryngeal nerve; nerve section was done, and for three months the patient has been free of stabbing pains in the throat that had occurred whenever he swallowed and sometimes when he did not. I was able to establish a diagnosis through differential nerve blocks to show that stellate block would not relieve him but that a block of the superior laryngeal nerve would give relief.

A Look Forward

It would be interesting to know what the immediate future holds for us in this field. It is quite possible, and perhaps probable, that greatly simplified devices will replace our present gas machines. There is not much doubt in my mind that in the immediate future we will no longer say "nitrous oxide and oxygen" but we will reverse the order and say "oxygen and nitrous oxide." The trend, I think, is definitely in the direction of placing the burden of anesthesia on the preliminary medication and intravenously given medicaments, plus muscle relaxants. This trend has validity for many reasons: for one, the fire and explosion hazards of anesthetics can be reduced or abolished thereby. The use of an intratracheal tube, however, becomes important, since respiration frequently is depressed to some extent and therefore the need for oxygen is paramount. Consequently, all the oxygen necessary to approach an arterial oxygen saturation of 100% will be used, and the rest of the breathing space will be occupied with nitrous oxide.

In view of the scarcity of personnel to administer anesthetics, I am sure that more and more visual aids will be employed in teaching. As an example, I am making a gauge with which to teach the newcomer how far to insert an intratracheal tube. As a result of this experience I believe I can say that in the future intratracheal tubes will be marked in such a way that, so long as the mark is visible above the larnyx, the point of the tube will reach about the midpoint of the trachea.

The population of the United States is increasing so rapidly that we must find some quicker way of teaching anesthesia techniques. In 1926 I published a paper entitled "Balanced Anesthesia," and now, 30 years later, I can see that, while I had part of the idea in 1926, I was handicapped because of a lack of agents with which to balance anesthesia adequately. I think that we now can more truly speak of "balanced anesthesia" as a reality than we could 30 years ago. At that time J. T. Gwathmey was speaking of the synergistic action of morphine and magnesium sulfate. He also had the idea that one drug could be made to help another, and, now that such drugs are available, a new flexibility has been established. Anesthetic agents will not have to carry the entire burden of relief of pain during operation, and so smaller and safer doses will be employed. I do not mean to imply that the person employing these agents can do so mechanically. He will have to be well informed and skillful; he will have to know more and more about more drugs and not less and less about them. However, if instruction in some lines can be accelerated, it will leave more time for a better understanding of pharmacology in anesthesiology.

In the past we treated shock when it occurred. I submit that in the future prophylactic treatment of shock will be possible. I think this will be the outgrowth of a better understanding of the hormones. It is my hope that in some way in the future we will be able to desensitize patients, especially to antibiotic agents, for, as progress is made in the development of new remedies for illness, we are constantly faced with the concomitant creation of new hazards. We shall need protective assistance in order to survive and to treat more and more conditions that either have been unrecognized or have been resistant to our treatment.

I have no doubt that devices for monitoring a patient's condition will come into use. These doubtless will include a communication system that will make it possible for expert supervision and advice to be quickly available, not only in every operating room but also in every postanesthesia observation room and no doubt, in time, in each room in the hospital. The hospitals of the future, I think, will be very different from those to which we are accustomed. The transportation of patients within the building could be improved. When the burden of patients who will have to be cared for is considered, it is seen that means will have to be devised so that one physician or one nurse or even one orderly will be able to increase his work load. Certainly, those of us in medicine and its ancillary fields will always be outnumbered by an ailing population, which means that our only hope is to increase our personal efficiency. There will be many improvements that I am not able to foresee. Time does not permit indefinite speculation and prudence precludes it, but I am grateful when I reflect that I lived in an era in which so many marvelous developments were made. I am confident that patients of the future will be cared for better than I could envisage. I am sure that those who are entering the specialty of anesthesiology will derive untold satisfaction from their activities, particularly because they will have at their command what their forebears did not: an impressive array of agents and methods that, by virtue of their infinite variety, can swiftly be exploited to meet the exigencies presented by any type of patient or condition. Those will be happy days indeed, and I am glad it will be so.

ELEMENTS OF A RURAL RHEUMATIC FEVER PROGRAM

Harry A. Grubschmidt, M.D., Santa Rosa, Calif.

• The community rheumatic fever program here described has been administered by a county department of health under the auspices of a state crippled children service, with funds coming from both county and state. Local medical, laboratory, clinic, and hospital facilities are utilized. The plan has been to encompass all aspects of the patient's illness, to enlist the cooperation and continue the education of the patient's family as to his illness, to keep adequate records, and to formulate policies that would insure the cooperation of the physicians and of the interested official and voluntary organizations. Volunteer helpers made it possible to maintain a large anteroom as a combined reception, dressing, and recreation area, which made it much easier for families with several children. Volunteers also served in clerical capacities, provided necessary transportation, and in some instances donated professional services. The program resulted in more accurate diagnoses, more systematic treatment, and a striking reduction in the incidence of active rheumatic fever in the program's patient population.

It is the purpose of this discussion to outline the structure of a successful rheumatic fever program achieved through a fusion of community effort and resources and the California State Crippled Children Services. The enthusiastic support of numerous volunteer workers and the assistance of voluntary and official agencies made it possible to establish an all-embracing program in a rural community with a scattered population, despite limited financial support. The success of the project after five years is indicated by the reduction in the number of cases of active rheumatic fever, the prevention of complications, and the high percentage of follow-up visits. Our results have paralleled those achieved in other sections of the country where good medical care and adequate educational campaigns are operative.

The acute problem has now been met. The decrease in the number of patients with active rheumatic fever during 1954 and 1955 has allowed us to release most of our volunteer helpers and to suspend many of the activities described in the following pages. It is hoped that an account of the operation of the program and of the techniques and procedures worked out during the first five years of its existence will aid in solving the same or similar problems in other rural areas. In this discussion the medical aspects will be mentioned only to bring out the scope of the project; the emphasis will be on its organization.

Summary of Operation

The rheumatic fever program, which was officially begun in February, 1951, under the auspices of the California State Crippled Children Services, is administered by the Sonoma County Department of Health. Funds come from both county and state, and local medical, laboratory, clinic, and hospital facilities are utilized. The program serves a widespread rural area with an approximate population in 1951 of 105,000 people. All persons under 21 years of age who reside in the county are eligible for care. The physical facilities are situated in Santa Rosa, the county seat, the largest and most centrally located city in Sonoma County. The clinic building utilized for the project is located on the grounds of the Sonoma County Hospital; the hospital also provides x-ray and laboratory facilities. A special section of the pediatric ward of the hospital is reserved for patients assigned through the program. This is advantageous since it provides nursing personnel experienced in handling children. Also, because this section is adjacent to the hospital schoolroom, the children can be wheeled to class in their beds early during their hospital stay and can continue their schooling in familiar group fashion.

Patients are referred chiefly by physicians, either from their office practices or in their capacity as medical examiners in the public schools, and also by school health nurses, teachers, and parents. After a patient has been referred, the family is sent a notice to bring the child to the laboratory and x-ray departments on a specified day. On that day one blood sample is drawn for the required examinations, and throat swabs, urine specimens, x-ray films, and electrocardiograms are taken. The patient is then instructed to appear at the clinic five days later for examination.

The clinic is held at the same time on the same day each week throughout the year, except on legal holidays. Patients are seen by a local cardiologist and a pediatrician, assisted by public health nurses assigned by the Sonoma County Department of Health. The two physicians make the initial and follow-up examinations and consult freely with each other. The current laboratory and x-ray data and the patient's chart, including data from a questionnaire filled out by the parents and a Wetzel grid, are reviewed by the physician at the time of each examination. When necessary, consultation with medical specialists in the same or other fields is made available to the program physicians through the Crippled Children Services of the State of California, which also provides prophylactic medicaments as needed. Ancillary services, such as vocational rehabilitation, dietetic aid, and social service consultation, are also at the disposal of the medical personnel. The local health department is responsible for making appointments, keeping records, and acting as an interdepartmental liaison agent.

From the Department of Medicine, University of California School of Medicine, San Francisco, and Director, Sonoma County Rheumatic Fever Program. The Sonoma County Rheumatic Fever Program is sponsored by the Crippled Children Services of the State of California.

The program is set up to provide local facilities for the diagnosis and care of active and inactive cases of rheumatic fever and the referral of cases of congenital heart disease as they are discovered. The disposition of cases includes direct admission of acutely ill patients to the hospital for diagnostic study and care, hospitalization or bed care at home for patients with active rheumatic fever, and appointments for follow-up examinations at the clinic for patients who are to be watched. Convalescent patients are sent home or to a facility in a nearby metropolitan area (about 60 miles distant). Patients who have diseases other than rheumatic fever are referred to the family physician or an appropriate clinic.

Objectives

At the time the program was organized in 1951, the group established certain broad aims that would insure maximum satisfaction, not only to the patients and their families, but to the personnel of the program as well. These objectives were as follows: 1. Care was to be as all-encompassing as possible; all aspects of the patient's illness, including familial and environmental factors, were to be the concern of the group operating the program. 2. Every effort was to be exerted to secure the good will and cooperation of the patient and his family in carrying out instructions, keeping appointments, and insuring continued observation. 3. Full and accurate records on individual patients and on the progress of the entire program were to be maintained. These records would be evaluated periodically as a guide in modifying the direction of the program's activities. 4. A plan of continuing education of patient and family was to be put into effect to stimulate their interest and to aid them in cooperating intelligently in the management of the patient. A wider aspect of this educational project would be extended to the county population in general and also to physicians. 5. At all times the policies of the program would be shaped to win the cooperation of physicians in the county and of the official and voluntary agencies that were interested in the patient.

Recruitment of Outside Assistance

It quickly became apparent that these objectives could not be fully attained with the limited funds and facilities available, unless we could interest other groups in working with us. To acquaint other groups with the program, a luncheon meeting was held on the second and fourth weeks of each month after the morning clinic. Representatives of various public agencies and associations were invited to sit in with the group and discuss the program. Special emphasis was laid upon the role they could play in helping us reach our first objective—maximum well-rounded care for the patient. A partial list of the agencies and groups invited included state-sponsored consultants in public health, dietetics, recreational therapy, physical therapy, medical social service and policy-making; personnel from the division of vocational rehabilitation and school health nursing; a school psychologist; departmental heads of the city and county school systems; county librarians; members of the Council of Churches, the county social welfare department, and various nursing organizations; personnel from the laboratory and x-ray departments of the county hospital; representatives from various lay organizations that had active health and welfare committees; interested physicians from the county medical society; and home and hospital teachers. In addition, a call was put out for volunteer helpers; this was done by active solicitation of various clubs and public agencies and by personal approach to friends and acquaintances. The response was gratifying and included persons with special skills of value to the program.

Use of Volunteer Workers

The assistance of volunteer workers made it possible to achieve our second and third objectives. A volunteer acted as recreational supervisor in the large anteroom used as a combination reception-dressing area where the patients, their parents or guardians, and their siblings assembled prior to and during the time the patient was seen in the examining room. This worker supplied much of her own equipment, including record player and records, paints, crayons, puzzles, picture books, paste and papier mâché materials, transparencies, and viewers, and set up a highly effective play area. A local businessman donated tables and chairs suitable for children, and other community members contributed play materials.

All the children, both patients and their brothers and sisters, were welcome to enjoy the recreational facilities. This encouraged early arrivals at the clinic, where patients were seen on a first-come basis, since the parents knew the children would be kept occupied during any waiting period. It also made attendance easier for parents who could not leave their other children alone at home. The play project also allowed the public health nurses to weigh and measure patients and record pulse and temperature with a minimum of noisy interference, to counsel parents on diet, hygiene, and interpretation of physicians' orders, and to orient parents of new patients in the work of the program. It gave parents undisturbed time to construct a "life chart" in the case of new patients and to fill out the simple questionnaire on interval history that was required at each visit.

Two additional volunteer workers assisted in the reception-dressing room in recreational supervision or in helping the nurses. As they developed experience they were able to substitute adequately for any of the members of the group who could not attend a clinic session. A clinical psychologist with considerable experience in dealing with school children volunteered her services. It was her function to alert the group to any important emotional problems; she also carried out systematic mental testing and interpreted the "life charts" that were used to evaluate the emotional needs and mental capabilities of our patients. In instances of acute emotional disturbance, therapy was started by this volunteer worker until a more permanent arrangement could be made.

Another volunteer served in a clerical capacity, classifying and filing the records of the patients according to diagnosis. A special flagging system permitted prompt identification of charts of persons with currently active or inactive rheumatic fever, as well as those with a primary diagnosis of congenital heart disease. This worker also kept a record of these cases on a county map by means of pins with colored heads, each color designating a different diagnostic category. The map, files, and a numerical tabulation were revised each week in accordance with the changes that had taken place, and the results were made available to the group in staff conferences. Another volunteer was trained to plot the Wetzel grid kept currently on each patient.

It was hoped that volunteer workers could be found to relieve the mothers of patients cared for at home, giving them one free afternoon a week. This proved difficult, since untrained persons are usually unwilling to accept the responsibility of supervising a sick child in a strange home. The volunteer recreational therapist, however, did make one or more home visits to instruct the mothers of newly confined patients on ways of entertaining a bedridden child. Where transportation to the clinic was a problem, voluntary agencies, such as the Red Cross, were able at times to provide cars and drivers, or occasionally an individual would offer her services. At other times, the public health nurses used their own automobiles to call for and return patients.

Staff Conferences

After each clinic session, the two physicians, the public health nurses, and the volunteers met to discuss the medical and sociologic aspects of cases in patients seen that morning. Each person was encouraged to speak freely. Recommendations were noted, and the responsibility for seeing that they were carried out was placed with the public health nurse in whose district the patient resided. The progress of patients seen previously who had required special handling was briefly reviewed. Luncheon meetings followed these weekly staff conferences; the first and third of these in each month were devoted to discussing the operation of the program as a whole, including inadequacies and plans for improvement. These meetings generated a spirit of unity among the members of the group, which was responsible for much of the enthusiasm that made it possible to carry out the routine of the program week after week.

Education

As stated in our fourth objective, the group agreed that much of the ultimate success of the program lay in a continuing and effective educational plan. The first steps were directed toward acquainting parents and patients with the natural history of the disease through weekly contact with the public health nurses at the clinic and by means of brochures, pamphlets, and instruction sheets. Elements of good dietary practices and details of home care were taught largely through home visits by the nurses. In cooperation with the local Heart Association, the group sent pamphlets on rheumatic fever, its recognition, and the need for action to every student at the elementary school level and to every teacher in the county.

A one-meeting course in rheumatic fever, supplemented by multigraphed descriptive literature, was arranged for public health and school nurses of Sonoma and adjacent counties. With financial assistance from the director of the Sonoma County Health Department and technical aid from the county photographic department, the operational steps of the program were filmed on 35-mm. color slides. The film, followed by talks on rheumatic fever by the physicians and public health nurses associated with the program, was shown to women's clubs, parent-teacher associations, and similar groups all over the county.

Function in the Community

Our fifth objective was that of establishing reciprocal cooperative relations with the community. To be successful the program should be well received by all, and in turn should be the recipient of benefits from the community. To aid in accomplishing this objective, duplicate reports of the findings and recommendations in each case were sent to the appropriate school authorities, the county school psychologist, and, when known, to the family physician. Other official agencies were notified whenever they were concerned with the patient's welfare. In turn, the agencies would offer their aid. For example, at our request the welfare department would grant temporary dollar increases to needy families for the purchase of food or medicaments. The county librarian, together with the county health department educator, assembled books and magazine articles on rheumatic fever, home nursing care, games and hobbies, and similar subjects, which were kept on a separate shelf in the library; the list of this material was published in the local newspaper. The county library bookmobile was kept informed of the location of homebound patients throughout the county, and efforts were made to get pertinent reading matter to them. The school health nursing division reported to the program children who were absent from school for suspected or known rheumatic fever. Reports of new cases, however, were made in somewhat sketchy fashion. It was not possible to solve this problem completely, despite the fact that rheumatic fever is a reportable disease in this county. Other county and state agencies also gave their services. The partial list of the organizations that sent representatives to our luncheon meetings, as described earlier, indicates the scope of the assistance given to the patients and families concerned in this program.

Results

Over 550 patients have passed through the clinic during the five years the program has been in operation. Of this number, the conditions in approximately 140 were diagnosed as inactive rheumatic fever with or without residual heart disease and in approximately 50 as congenital heart disease with or without associated rheumatic fever. In 90 cases a definitive diagnosis has not yet been made, and the patients are still under observation. Some of these patients have equivocal histories but there are no objective findings; others have vague symptoms and heart murmurs that cannot be interpreted definitively. The remaining patients are regarded as not having had rheumatic fever.

During the total five-year period, no more than 10 patients refused or failed to return for further observation. In most cases in which patients with inactive rheumatic fever have returned to private care, their physicians have usually permitted us to examine them at least once a year. In addition, we have been able to maintain good rapport with our patients to the extent that they will return to the clinic for check-up examinations whenever requested to do so. Thus, we have been able to achieve a high percentage of follow-up studies in our cases.

During the five years of the program's activity, the number of cases of active rheumatic fever has diminished steadily. Thirteen cases were treated in 1951, 14 cases, 5 of which were recurrences, in 1952, and 25 cases, 5 of which were recurrences, in 1953. In 1954, six cases were seen, only one of which was due to recurrence. In 1955, we saw only one case of active rheumatic fever and no recurrences.

The progressive decrease in recurrences resulted in some measure from improvements in our methods of prophylaxis. During the first two years of the program, the type of antibiotic, the dosage and duration of treatment, as well as the choice of patient, were left to the discretion of the physician. As more information was obtained, penicillin, 200,000 to 400,000 units daily, was prescribed automatically for all patients with a diagnosis of active or inactive rheumatic fever unless they were sensitive to the drug, in which case use of a sulfonamide was substituted. During the last year, benzathine pencillin G, in a dose of 200,000 units once daily, has been employed as a prophylactic agent. The regularity with which patients take medicaments is also important in prophylaxis. Although we have no accurate way of determining this factor, the fact that the antibiotics are supplied through the program provides a rough check. Initially, about half the patients neglected to have their prescriptions filled regularly. As our mutual understanding improved, most of the patients began to renew their prescriptions at the anticipated intervals, indicating that they were taking their medicament faithfully.

The cost of the program per patient's clinic visit was estimated from the figures available for 1955, which were fairly typical of the five years of our operation. During this year the patients' visits totaled 473, of which 78 were initial visits. The estimate was based on the cost of all laboratory tests (complete blood count, sedimentation rate, urinalysis, antistreptolysin titer, C-reactive protein, Venereal Disease Research Laboratory test, Brucella agglutination, and throat culture), electrocardiograms, x-ray films, and prophylactic medicaments but did not cover hidden expenses, such as physicians' services, clinic space, public health nursing, stationery, and similar items. On this basis, the average total cost per patient per clinic visit amounted to $4.64.

MEDICAL SOCIETY GRIEVANCE COMMITTEES IN RELATION TO HEALTH AND ACCIDENT INSURANCE

Percy E. Hopkins, M.D., Chicago

• *Grievance committees within county and state medical societies have been active for at least four decades. Originally involving only the patient and the physician, they now deal also with insurance companies and other organizations concerned with the financing of medical care. A survey of 254 cases filed with a county medical society in 1955 shows that such a committee can be very effective in preventing or resolving misunderstandings, clarifying and adjusting differences between physicians and patients, and assisting in the maintenance of high levels of professional deportment. It is necessary that the public be informed of the existence of grievance committees and be encouraged to use them.*

Inasmuch as the purposes of grievance committees are to prevent or resolve misunderstandings, to clarify and adjust differences between physicians and patients, and to assist in maintaining the high levels of professional deportment already established by the Principles of Medical Ethics, and because of the fact that a great number of people are protected by health and accident insurance today, it is only natural to anticipate increasing contact between insurance companies and medical society grievance committees. I believe it is reasonable to predict also that as a greater number of people purchase health and accident insurance, and especially types of coverage in which the benefits are not specifically delineated, such as major medical expense contracts, it might become necessary for these two groups to maintain rather close liaison in order that misunderstandings might be prevented. I have complete faith in the integrity of the medical profession as well as that of the insurance industry, but I realize that a dollar will purchase only so much in the way of a benefit and that the average physician is now confronted with the fact that a large percentage of his patients have some type of insurance. Occasionally, perhaps the patient and the physician anticipate a greater benefit than is actually provided. This, with a third party appearing on the scene, could result in some misunderstanding on the part of the patient or the physician.

For instance, the patient could assume that the specific benefit to which he might be entitled would be sufficient to compensate the physician adequately

---

Read in the Educational Seminar, conducted by the Bureau of Accident and Health Underwriters and Health and Accident Underwriters Conference, New York, Feb. 7, 1956.

for the service rendered, but, in the absence of an agreement to that effect, the physician could have some other idea about the matter. Both patient and physician might be entirely sincere in this regard, and such a situation should offer little difficulty of solution if the patient is informed as to the benefits provided for. Such a situation would probably not be one in which the insurance company would be involved, but, if the patient feels that the charge is unusual, the matter should be brought to the attention of the grievance committee of the county medical society of which the physician is a member. It is my humble opinion, with regard to the financing of the costs of medical care, that insurance companies in every instance in which they are the responsible party are entitled to the same moral, ethical, and civil rights as the individual in utilizing the service of grievance committees of the medical societies.

Organization of Grievance Committees

Recently, the House of Delegates of the American Medical Association authorized the appointment of a committee to act as a guide in the organization and functioning of grievance committees in the constituent associations and component societies (state and county). The House of Delegates was quite specific in stating that these committees were to be known as grievance committees and encouragement was to be given to the constituent and component societies not only to cause these committees to be organized but to get them functioning. This committee at the top level in the American Medical Association has set up guides that may be adapted to fit local conditions with regard to the organization and functioning of the local committees and should be of great help in improving their effectiveness.

It is interesting to note that the idea of grievance committees within state and county medical societies was conceived years ago. The Chicago Medical Society has had such a committee that has been active since as early as 1917, if not earlier. In the past 10 years the number of grievance committees has grown rapidly, until today all 48 state medical societies, those of the District of Columbia and Hawaii, and over 700 county medical societies have committees functioning as grievance committees where the public (and insurance companies) may take their complaints.

Committee Membership

The make-up of committees may vary in different states, and this is only natural inasmuch as there are variations in the geography and population among the states and territories served. These factors might influence the number of members on a committee. In some areas where membership in a medical society is limited, it might be impracticable to have more than a small number of physicians serve or get together at one time to conduct a meeting, and in other areas a more nearly ideal committee might be composed of 7 to 10 members having regard to type of practice, age, experience in medical organization, geographical location, and temperament.

While committees have been organized at the state, as well as at the county, level there is no intent to violate a component society's autonomy, nor does this constitute a duplication of organization or effort. There are some county societies that have such a small number of members that they do not have grievance committees, and in some small societies it would probably be impossible for any one member to be the subject of investigation by his few colleagues in the county. Again, for certain reasons known best by the individual, a physician, the subject of a charge, might feel that he would like to have a change of venue or have his hearing conducted at the state level. Other reasons may exist that also make a state committee desirable. The state committee may also be used as a court of appeals and is set up primarily to help the component society in any manner possible. Members on these committees may be elected or appointed, with members serving overlapping terms so that experienced men will always be serving. Members of a grievance committee should not simultaneously serve or act on committees having to do with discipline.

Filing of Complaints

A complaint may be filed at either the state or county level and in most instances will be adjudicated at the local level. When such a grievance is presented in writing to the secretary of the state or county medical society, it will automatically be referred to the grievance committee at the level that is to hear it. Naturally it is desirable that these grievances be adjudicated at the local level, but, as has been previously stated, this may be impracticable. In either event, the grievance will be referred to the grievance committee at the proper level under the circumstances. Complaints against physicians should be submitted in writing with all pertinent facts and details pertaining to them. The presentation of specific data frequently will result in the prevention or correction of a misunderstanding between complainant and complainee, bringing about a saving of time and expense that an appearance would require and perhaps even the settlement of a difference to the satisfaction of all concerned.

There should be no limitation upon the sources of complaints other than that the source be sincere, whether it be public or private, professional or lay. Complainant and physician should be privileged to appear before the committee and present whatever witnesses or evidence seems desirable. The right to appeal the decision of the grievance committee to the appropriate superior body should be provided for under any grievance committee organization arrangement.

Conduct of Investigations

A prerequisite to any investigation by a grievance committee requires that the member must respond to any reasonable demand on the part of the committee, although it should be distinctly understood that the physician summoned before a grievance committee is not on trial. Failure to respond to the committee's invitation usually results in the filing of charges that could imperil a member's standing in his society. While a grievance committee should be empowered and willing to initiate investigations when matters justifying action come to its attention, it should be remembered that its function is to investigate, mediate, arbitrate, and possibly recommend disciplinary action. It should never act as a trial body. All medical societies should have other bodies or committees specifically designed for that purpose.

While there may be a few exceptions, it has been my experience with grievance committees over a considerable number of years that there is evident an avowed purpose among the members to be consistent, sympathetic, and impartial because there is a realization that the honest and capable physician is afforded protection as well as the patient or complainant. To the average physician sitting on a grievance committee, the thought of participating in a so-called whitewashing procedure is just as abhorrent as the other extreme of washing our professional dirty linen in public.

Informing the Public

Inasmuch as grievance committees are designed for the use of the public, it is necessary that the public be informed of their existence and encouraged to use them. Such publicity in the past few years has undoubtedly caused an increase in the number of complaints filed against doctors, but it is my belief that this is only the peak of a wave that will level off and probably recede. It is undoubtedly just as important to keep the medical profession informed through professional mediums, such as medical journals and news letters, of the volume and progress of the work done by the committee. Release of such information through the lay press could perhaps defeat the purpose for which the committee was designed by causing a flood of complaints by persons with grievances that are largely unreasonable or unrealistic.

Report of a Committee

This brings to mind the problem of abuse of these committees, and I do not hesitate to voice an opinion that there is not much likelihood of an insurance company's abusing the privilege of utilizing these grievance committees. In a survey of 254 cases filed with a county medical society during the year of 1955, it was found that at least 10 complaints had been filed by people who were so patently mental cases that further consideration by the committee was abandoned. In three cases a misunderstanding existed that the committee was able to explain, which resulted in withdrawal of the complaints. In 55 cases, after full investigation, the committee was of the opinion that the complaint was not justified. These complaints had to do with treatment and fees or both. In 119 instances in which complaints were made because of excessive fees, the charge of the physician was sustained. In 58 complaints (out of a total of 254) the physician adjusted his fee, or canceled his bill entirely to conform to the recommendation of the grievance committee. In one instance a complaint was made because of the persistence of a physician in attempting to collect a fee from his patient for services that were rendered under the Workmen's Compensation Act. In some instances the physicians were reprimanded for lack of cooperation with the committee, and in a few cases referral of the case was made to committees having to do with the investigation of unethical conduct. Among the 254 cases above referred to are included eight inquiries or complaints by insurance companies, five of which had to do with fees. Some of these requested information as to the fairness of a fee.

No mention is made anywhere in this report of abuse in utilizing the services of the committee, despite the fact that 10 of the complainants were frankly psychotics, and in 119 instances the committee found the complaints unjustified or not sustained. It is interesting to note that a psychiatrist has recently been added to the personnel of this committee, seven members now constituting the committee. It is to be noted in connection with this committee's report that approximately 70% of the complaints had to do with fees. It is equally interesting to find that of this number, in about one-third of the instances, either an adjustment was made or the bill was canceled. In neither instance was the size of the adjustment stated, nor the number of cases in which the bill was canceled.

In connection with fees, you will recall that I previously stated that among the grievance committee's functions are those of arbitration and mediation. In its capacity as arbitrator, it should be in a position to determine what is a usual fee or an unusual fee under specific circumstances. I believe the chairman of a local grievance committee in most instances, if the circumstances are made plain to him, should be able and willing to determine the unusualness of a fee or vice versa. If he is unable or unwilling to decide this question himself, the matter would then have to be considered by the whole committee. While grievance committees rightfully will shy at setting a physician's fee for services rendered, there are and will continue to be fees that may seem to be unusual for a specific service. In such instances the committee should be vitally interested in determining whether the fee is unusual or if, under the circumstances, the services were unusual or extraordinary.

My purpose in mentioning this committee's report above is to point out that here is a county medical society committee composed of sincere, serious-minded, busy physicians devoting a large amount of time and effort without compensation to accomplish a worthwhile job for the public and the medical profession. I believe it is representative of the average grievance committee already in existence and functioning throughout the country. I am confident you will find these grievance committees attentive and sympathetic to your inquiries and hope they will be of aid in helping to iron out some of the difficulties encountered in the process of providing better health care throughout the nation.

800 W. 78th St. (20).

CLINICAL NOTES

INDUCTION OF CARDIAC PAIN BY ORALLY GIVEN TOLAZOLINE (PRISCOLINE) HYDROCHLORIDE

John D. Davidson, M.D., Bethesda, Md.

It is not generally appreciated that cardiac pain can be induced by adrenergic blocking agents in patients who have a history of arteriosclerotic heart disease. The precipitation of such pain by orally administered tolazoline (Priscoline) hydrochloride has apparently not heretofore been reported. It is the purpose of this study to present a case in which such a reaction was induced on three separate occasions by orally given tolazoline and once by Dibenzyline (N-phenoxyisopropyl-N-benzyl-β-chloroethylamine hydrochloride) given under relatively controlled conditions. A mechanism whereby this reaction may take place in the absence of changes in pulse or blood pressure is suggested.

Report of a Case

A 65-year-old widow was admitted to the National Heart Institute for evaluation of hypertension of 25 years' duration. She felt well until five years prior to admission, when she experienced an acute depressive episode that necessitated electroconvulsive therapy, after which she made a rapid and uneventful recovery. One year prior to admission she developed intermittent pain of the lower part of the left leg on walking two blocks. This symptom continued essentially unchanged until six months prior to admission, at which time she noted, in addition, the onset of epigastric and substernal aching pain that was usually associated with severe aching of the forearms bilaterally. This pain was precipitated by heavy meals and walking and was promptly relieved by rest and administration of glyceryl trinitrate (nitroglycerin). Four months prior to admission, therapy was begun with whole root extract of Rauwolfia serpentina, moderate sodium restriction, and a reducing diet, which resulted in a 29 lb. (13.2 kg.) weight loss, without change in her symptoms or blood pressure. Her mother, four siblings, and son have high blood pressure.

On admission her blood pressure was 270/140 mm. Hg. Funduscopic examination revealed narrowed and tortuous arterioles, increased arteriolar light reflexes, and arteriovenous nicking. No hemorrhages or exudates were seen. Cardiomegaly was manifested by an apical impulse 14 cm. from the midsternal line. There was a grade 3 high-pitched, blowing systolic murmur at the apex, which was also audible along the left sternal border and transmitted to the base. Diminished dorsalis pedis and posterior tibial pulses were noted bilaterally. Chest roentgenogram and cardiac fluoroscopy revealed moderate left ventricular enlargement, calcification of the aortic knob, and marked elongation and tortuosity of the aorta. The electrocardiogram revealed slight S-T segment depression in leads V_5 and V_6 with upright T waves across the precordium and was interpreted as showing left ventricular strain. Phenolsulfonphthalein excretion was 54% in two hours with 20% excretion in the 15-minute specimen. After administration of amobarbital (Amytal) sodium, the blood pressure fell from 260/160 to 134/92 mm. Hg. Routine urinalysis, serology, hemogram, and blood chemistries, as well as basal metabolic rate and intravenous pyelogram, were within normal limits.

The patient was exercised on a treadmill at zero grade at 4 mph for six minutes, at which time she developed a cramping pain in the lower part of her left leg. Treatment was begun with administration of 12.5 mg. of tolazoline orally four times a day (fig. 1), and the dose was increased to 50 mg. four times a day by the seventh hospital day. At this time the patient noted severe chest pain even while supine, which was accompanied by marked diaphoresis, apprehension, and increase in pulse rate from 70 to 90 beats per minute. Her blood pressure remained unchanged, and administration of glyceryl trinitrate afforded prompt relief. On the following day, the pain again recurred with greater intensity, but administration of glyceryl trinitrate and carotid sinus pressure with cardiac slowing failed to give satisfactory relief. A repeat electrocardiogram at this time revealed inverted T waves in leads V_4, V_5, and V_6 and was interpreted as representing left ventricular ischemia. On the ninth hospital day, dosage of tolazoline was increased to 100 mg. four times daily and the patient's chest pain became still more severe and required meperidine (Demerol) hydrochloride therapy for relief. Tolazoline therapy was discontinued the morning of the 11th hospital day, and by midafternoon the pain was gone. After five and a half days had elapsed without intervening chest pain, she was given 100 mg. and then 50 mg. of tolazoline under the guise of another medicament. On both occasions typical cardiac pain recurred, with radiation in both forearms, sweating, and increase in pulse rate to 90 beats per minute, and required administration of meperidine for relief. These episodes were separated by two weeks of freedom from chest pain. Exercise on a treadmill in this interim again evoked only leg pain after six minutes at 4 mph, zero grade.

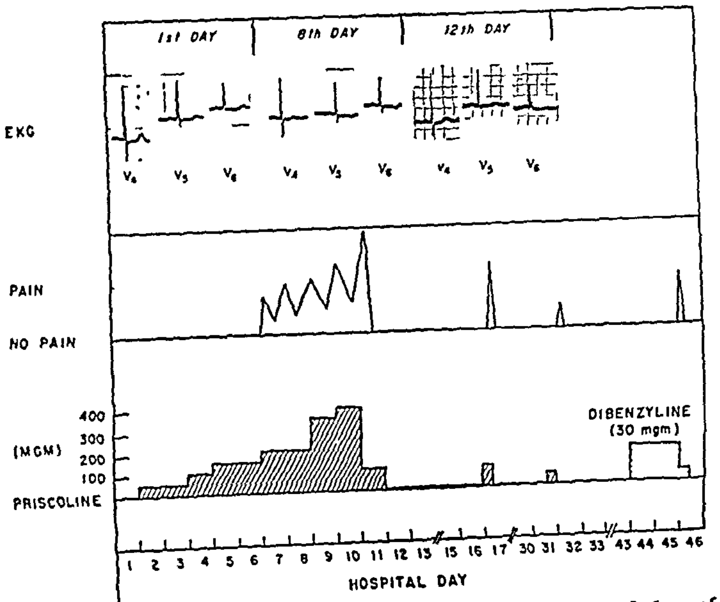

Fig. 1.—Relationship of patient's myocardial pain to time and dose of adrenergic blocking agent and electrocardiographic changes.

Her subsequent hospital course was uncomplicated until the afternoon of the 44th hospital day, when Dibenzyline was administered in order to see if other adrenergic blocking agents could induce a similar reaction. She received 60 mg. over the next 48 hours, when anginal pain, promptly relieved by glyceryl trinitrate therapy, recurred while she was lying in bed. After several days of being pain-free, she was given azapetine (Ilidar), 300 mg. daily, for several days and then later a 10-mg intravenous injection of phentolamine (Regitine) methanesulfonate without adverse effect.

Comment

Although the fact that cardiac pain may result from administration of tolazoline is not generally appreciated, there are several references to this relationship in the literature. Grimson[1] regarded as coincidental the development of myocardial infarction in two pa-

---

From the Clinic of General Medicine and Experimental Therapeutics, National Heart Institute, National Institutes of Health, Public Health Service, U. S. Department of Health, Education, and Welfare.

tients during therapy with orally and intravenously given tolazoline. Flasher and co-workers[2] studied the electrocardiograms of eight patients with essential hypertension or cardiac disease receiving tolazoline intravenously and reported ST-T wave changes in leads V_5 and V_6. It was presumed that these electrocardiographic changes represented a direct myocardial effect of the drug. A direct effect of this drug on the heart in the absence of changes in circulatory dynamics is supported by the report of Lippmann,[3] who noted anginal pain with abnormal electrocardiographic findings among the side-effects of intra-arterial doses in excess of 20 mg. Prolonged cardiac pain associated with flushing, apprehension, and tachycardia was reported by Sagall and Lewenstein[4] after 35 mg. of tolazoline was injected into the femoral artery of a patient who previously had been given 25 mg. of tolazoline four times daily by mouth without adverse effects. Four days after the injection, an electrocardiogram demonstrated elevation of S-T segments and inverted T waves in leads 1, AVL, V_4, V_5, and V_6, clinically considered to be consistent with an acute myocardial infarction. Prandoni[5] has observed anginal pain lasting from 30 minutes to three hours after injection of tolazoline intra-arterially in two patients who had previous infarctions.

Adrenolytic agents other than tolazoline have also been implicated in the induction of cardiac pain. In a case described by Fremont,[6] severe chest pain occurred during a hypertensive crisis after the intravenous infusions of another imidazoline, piperoxan [2-(1-piperidylmethyl)-1,4-benzodioxan hydrochloride]. Moser and co-workers[7] have reported the occurrence of an ischemic pattern in the electrocardiogram of a patient treated with a haloalkylamine, Dibenzyline. In a study by Miller, Ford, and Moyer,[8] in which experience with Dibenzyline in 32 hypertensive patients is reported, there were 3 patients in whom angina occurred in association with rapid heart action. Gill, Duncan, and Reinhardt[9] treated 21 hypertensive patients with Dibenzyline in doses ranging from 30 to 300 mg. per day and noted definite angina pectoris in 2 patients, while 2 others died with symptoms suggesting myocardial infarction. These investigators also noted tachycardia as a prominent undesirable side-effect of this drug but did not speculate in their report as to the mechanism of the angina in these cases. Cardiac pain after administration of azapetine has been recorded only in association with hypotension, which occurred during intravenous infusion of the drug at the rate of 1 mg. per kilogram of body weight over a 30-minute period.[10]

It is generally accepted that the effective stimulus for what we describe as cardiac pain is a diminished oxygen supply to the myocardium relative to its needs. The most likely mechanisms whereby drugs may induce this situation are (1) hypotension with decreased coronary perfusion pressure, (2) tachycardia sufficient to interfere with coronary filling, (3) direct constriction of coronary vessels, or (4) increase in cardiac work.

It is not apparent from the reports of Lippmann[3] and Sagall[4] whether cardiac pain can be evoked by tolazoline independent of blood pressure or pulse alterations. Neither hypotension nor tachycardia sufficient to evoke pain was found in the case reported here or in those of Flasher and co-workers.[2] The tachycardia that follows administration of adrenolytic substances in mammals is considered to be a reflex response to the fall in blood pressure. This has been demonstrated experimentally with Dibenamine (N,N-dibenzyl-β-chloroethylamine hydrochloride), tolazoline, piperoxan, ergot alkaloids, yohimbine, and Dibenzyline.[11] In the three cases observed by Miller and co-workers,[8] it was assumed that the tachycardia per se rather than hypotension was responsible for the precipitation of coronary insufficiency, because hypotension after administration of hexamethonium is not accompanied by cardiac acceleration and angina is rarely observed under these circumstances. Green[11a] feels that the side-effects of piperoxan hydrochloride, which may include substernal oppression, are attributable to a direct stimulation of many types of smooth muscle, including the coronary musculature. Against this as being the underlying mechanism in the case of tolazoline is the fact that this agent potentiates the augmented coronary flow induced by epinephrine.[12]

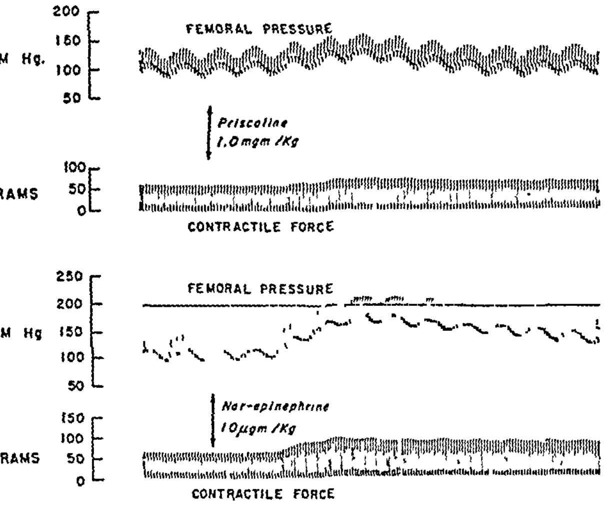

Fig 2.—Comparison of effect of tolazoline (Priscoline) and arterenol (norepinephrine) on blood pressure and myocardial contractile force of dog.

Experimental Study

The most likely explanation for the development of cardiac pain in the absence of cardiodynamic changes is a sudden increase in the work of a heart already embarrassed by arteriosclerosis or hypertension. By utilizing a strain gauge arch sutured directly into the myocardium,[13] a significant increase in cardiac contractile force was demonstrated after the administration of tolazoline. From figure 2 it can be seen that 1 mg. per kilogram of body weight of tolazoline will increase the contractile force of a dog heart approximately 25%, without significant change in blood pressure. In a heart already near the threshold of supply because of sclerotic vessels, the obligate increase in oxygen need may result in myocardial ischemia.

Summary and Conclusions

Cardiac pain could be induced repeatedly in a patient by oral administration of tolazoline (Priscoline) hydrochloride. This reaction is probably due to a direct myocardial action of the drug and is limited to patients with existing heart disease. Adrenolytic drugs should be used cautiously in patients who have coronary arteriosclerosis, and chest pain developing during the course of therapy for peripheral vascular disease with these agents may be more than fortuitous.

Figure 2 was supplied by Dr. Marion DeV. Cotten.

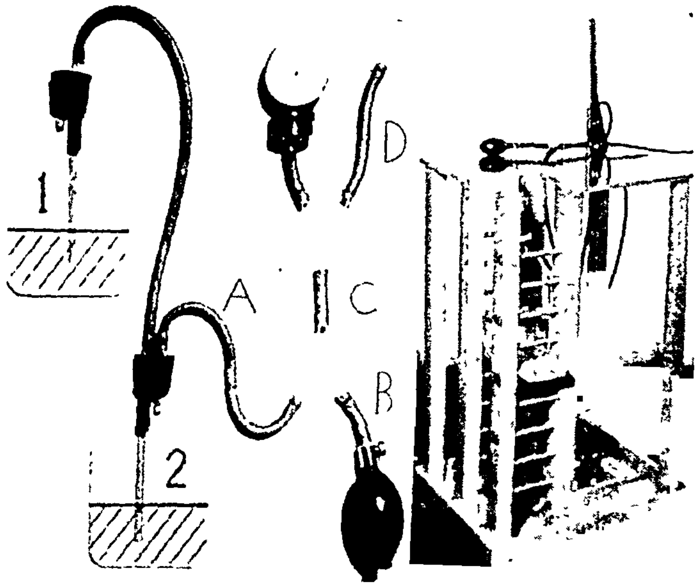
SIMPLE DEVICE FOR MAINTAINING CONSTANT PRESSURE IN SENGSTAKEN ESOPHAGEAL BALLOON

Shannon Brunjes, M.D., Los Angeles

The Sengstaken triple-lumen double-balloon nasogastric tube[1] has been of great value in the emergency therapy of hemorrhage from esophageal varices.[2] However, there has been little mention in the literature of the difficulty in maintaining a constant pressure in the esophageal balloon. A gradual fall in the pressure due to minute air leaks can be decreased by using new rubber tubing, clamping the tube leading to the inflating bulb, and tying all joints. In addition to the problem of leakage of air, there is a constant fluctuation of the esophageal balloon pressure due to changes in the volume of the balloon. These changes are related to changes in position of the patient, variations in intrathoracic pressure, and alterations in the muscle tonus of the esophagus and diaphragm. Even with a special nurse on duty to regulate the pressure constantly by adding or removing air, wide fluctuation in the pressure may take place.

In order to maintain a constant esophageal balloon pressure at any desired level without the necessity for constant adjustment, the following device was adopted, consisting of: two one-gallon jugs, two pieces of glass tubing (i.e., glass drinking straws), two two-hole stoppers to fit the jugs and with glass adaptors, two glass "Y" adaptors, one mercury sphygmomanometer (bulb and manometer—cuff not used), and 10 ft. of rubber tubing.

One jug is filled with water, and then half is poured into the other; it is important that the total amount of water used will fill only one jug. The apparatus is then assembled as shown in the figure, *left*. With tube C temporarily clamped, the bulb is pumped several times to force water through the siphon tube and prime the siphon. The pressure can then be set at the desired level by raising jug 1 to the required height. Jug 1 must be 5.35 in. above jug 2 for each 10 mm. Hg pressure desired. The device is made ready for use by raising jug 1 to the desired level with tube D temporarily clamped. The manometer is checked to see that the pressure is correct, and tube A is then clamped and the clamp on tube D is removed. After the tube is passed, the stomach washed, the gastric balloon inflated with 150 cc. of air, and the tube pulled up snug in the cardia and fixed, the esophageal balloon is ready to be inflated. Tube D is then attached to the Sengstaken tube esophageal balloon connection with an adaptor. The bulb (on tube B) is removed and replaced with a syringe. This is done so that the volume of air required to raise the pressure in the esophageal balloon to the desired level can be measured. This volume is usually about 100 cc. If it is much greater than this the esophageal balloon is probably bulging into the stomach and should be deflated and repositioned. When tube B is clamped and tube A unclamped the pressure will be automatically regulated. A program of gradual pressure reduction can then be carried out by lowering the upper jug in steps.



Left, assembled apparatus, showing correct placement of jugs 1 and 2 and positions of tubes (*A*, *B*, *C*, and *D*). *Right*, special cart that allows for adjustment of level of jug 1.

Resident in Internal Medicine, Los Angeles County Hospital.

If periodic deflation of the esophageal balloon is desired, this can be done by lowering jug 1 to the same level as the other jug.

Although the pressure is determined by the difference in the level of the water in the two jugs, for simplicity in explaining the apparatus, the level is considered to be constant in the jugs and the pressure is adjusted by raising or lowering jug 1. It should be noted that small jugs are not satisfactory because a small change in the volume of air in the system will produce a large change in the water level and, therefore, in the pressure. In case air accidentally escapes from the system, allowing the level of water in jug 1 to fall, this can be corrected in the following manner. The clamp is moved from tube B to tube D and the bulb is pumped slowly (to avoid excess pressure in jug 2) until the water is returned to the previously marked level. The clamp is then returned to tube B. Although it is possible to use this device by placing one of the jugs on the floor and one on a chair or table, it is more practical to assemble it on a special cart (see figure, *right*) that allows adjustment of the level of the top jug and that makes it available for immediate use as needed. This device has been used on more than a dozen different occasions during a five-month period and has proved quite satisfactory in maintaining a uniform pressure in the Sengstaken esophageal balloon.

Summary

The need for a method of maintaining a constant, but adjustable, pressure in the Sengstaken esophageal balloon instigated the development of a simple device. Although it can be quickly assembled from material available in any hospital, it is desirable to have it assembled on a special cart and available for immediate use. In use, this device has proved quite satisfactory.

SUCCESSFUL DEFIBRILLATION OF HEART

RESUSCITATIVE PROCEDURE STARTED ON MEDICAL WARD AND COMPLETED IN OPERATING ROOM

Herschel E. Mozen, M.D.
Richard Katzman, M.D.
and
John W. Martin, M.D., Cleveland

In almost all instances of successful defibrillation of the heart the procedure has been carried out in a surgical operating room, where the essential apparatus, supplies, and instruments were readily available. A few exceptions have occurred. These exceptions are sufficiently important to be reported, because they point the way toward the extension of the resuscitative procedure to areas in the hospital that are outside the operating room and possibly to areas that are outside the hospital itself. Two of these exceptional cases have occurred in the University Hospitals of Cleveland. The first[1] was in an ambulatory patient who had angina pectoris. As this patient was leaving the hospital after an electrocardiogram had been taken, he collapsed in what was considered to be a fatal heart attack. He was transported to a nearby operating room, and within minutes the chest was opened. The heart was emptied by hand massage while oxygen was delivered to the lungs. Defibrillation was successfully carried out. At the time of writing, eight months later, the patient, who is a physician, is actively engaged in the practice of medicine. The second of these cases is the subject of this report. Another similar successful defibrillation was carried out by Dr. C. David Brown[2] of Chicago. His patient was an x-ray technician who was developing plates when he collapsed. The chest was immediately opened. The heart was in asystole but fibrillation occurred when manual compression was started. The coordinated heartbeat was restored. The patient recovered completely. Later, an electrocardiogram showed a Wolff-Parkinson-White syndrome. Additional reports of successful resuscitation of patients who developed ventricular fibrillation outside the operating room have been published by Celio.[2A] Southworth and co-workers,[2B] and Reagan and co-workers.[2C]

In each of these instances the patient was in the hospital when fibrillation occurred. Fortuitous circumstances made successful resuscitation possible. The procedure in each case consisted of opening the chest, oxygenating the lungs, circulating the blood by hand massage of the heart, restoring the coordinated rhythm, and closing the chest. The facilities of the operating room were necessary in these cases. In order to extend the scope of resuscitation in cases of sudden ventricular fibrillation, it is desirable to bring together as many experiences as possible so that a course for future action can be charted.

Report of a Case

A 51-year-old female had been treated for two years by one of us (J. W. M.). She had rheumatic heart disease with mitral insufficiency and left ventricular enlargement. Her complaints were excessive fatigue, dyspnea on exertion, and palpitations. Pulmonary rales and peripheral edema were never noted. The eyegrounds were normal. The blood pressure usually was 120/70 mm. Hg. The pulse rate varied between 50 and 90 beats per minute. Frequent premature beats with occasional coupling were noted. Blood and urine studies had been normal. Her vital capacity was 84% of normal. Her basal metabolic rate was +7%. The electrocardiogram showed frequent ventricular premature beats and early left ventricular hypertrophy. The patient had taken 0.1 gm. of digitalis per day for two years. This had been reduced to 0.1 gm. every other day two months prior to admission. She had also taken 0.2 gm. of quinidine four times per day. This did not change the number of premature beats. On the evening of admission, the patient fainted while washing the dishes. There were no convulsions. She was seen by her doctor within 30 minutes. The pulse rate was 30 beats per

---

From the departments of surgery and medicine, University Hospitals of Cleveland and the Western Reserve University School of Medicine.

minute. The patient was pale. She answered questions but was lethargic. The blood pressure was 120/70 mm. Hg. Respirations were 26 per minute. The neurological examination was normal. She was admitted to the hospital, and an electrocardiogram was taken (fig. 1).

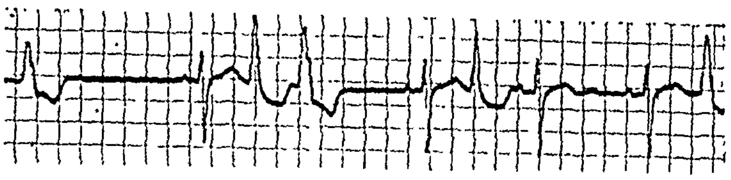

Fig. 1.—Lead V_1 of electrocardiogram taken on Sept. 22, 1955, at 11:20 p. m., showing frequent premature or interpolated ventricular beats.

On the following morning, the patient complained of fatigue. The pulse rate was 44 per minute. There were frequent premature beats. There was no evidence of heart failure. At 3:35 p. m. of the same day, the patient lost consciousness suddenly. She became deeply cyanotic. The blood pressure, pulse, and heartbeat disappeared. Several blows over the precordium failed to stimulate heart action. Two cubic centimeters of 1:1,000 epinephrine solution was injected into the heart. This was followed by the appearance of a sinus rhythm with multiple premature beats. The patient remained unconscious. The attending physician, who was contacted by telephone, ordered the intravenous administration of procainamide. However, while an electrocardiogram was being taken at 3:45 p. m., the rhythm changed abruptly to a persistent ventricular fibrillation (fig. 2). As a measure of last resort, the chest was opened rapidly through the left fifth intercostal space and manual compression of the heart was started. This was approximately two and a half minutes after the onset of the fibrillation.

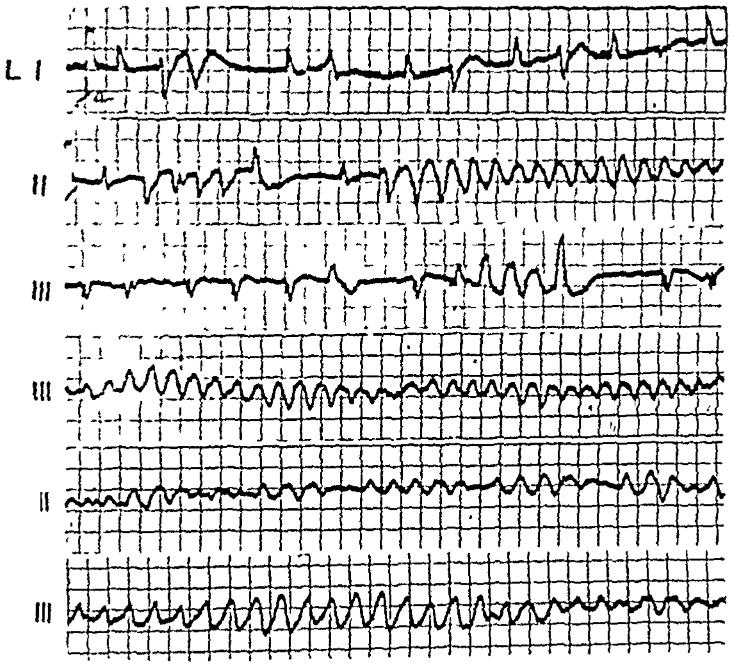

Fig. 2.—Electrocardiogram taken on Sept. 23, 1955, at 3:45 p. m., showing development of ventricular fibrillation. In lead 1 there are multifocal ventricular premature beats, some occurring in succession. In lead 2 a short burst of ventricular tachycardia (4 beats) is present. It is followed by the development of ventricular flutter (rate 300). Lead 3, taken approximately 20 seconds later, shows spontaneous subsidence of ventricular fibrillation and return of multifocal ventricular premature beats and paroxysmal ventricular tachycardia. However, ventricular fibrillation recurred within 12 seconds. Rows 4, 5, and 6 are portions of a continuous record taken during the subsequent 10 minutes. Ventricular fibrillation is persistent.

Aeration was accomplished by mouth-to-mouth breathing for about 15 minutes. The lungs were then inflated with 100% oxygen through a tight-fitting face mask. With the oxygen system reestablished, i. e., oxygenation of the lungs and hand massage of the heart to circulate the blood, the first step for successful resuscitation was accomplished. The emergency situation was under control, and further plans were made. It was decided to take the patient to the operating room to perform the second step in the resuscitation, i. e., restoring the coordinated beat.

The hand massage of the heart and the oxygenation of the lungs were continued throughout the 10 minutes spent in moving the patient through the corridors and up four floors in the elevator to the operating room. The patient was placed on an operating table, and the chest incision was draped. Defibrillation was then easily carried out with the application of a single electric shock. This was done through the intact pericardium. The time interval between the onset of fibrillation and the restoration of a coordinated heartbeat was 30 minutes. The heart was observed for one hour after the establishment of a regular beat. Since the heart continued to beat normally during this period and a good blood pressure level was maintained, a drainage tube was inserted into the pleural cavity and the chest was closed. A tracheotomy also was performed.

After the resuscitation, the patient was kept in a humidified oxygen tent for several days. She received vasopressor drugs for a few hours. She responded intelligently to questions that same evening. During the following few days, she had some lapses of memory but there were no gross neurological changes. The patient received procainamide for 22 days after the resuscitation. This was given intravenously for the first three days, in doses of 300 mg. every three hours. From the 3rd to 15th days, it was given orally in doses of 250 mg. every four hours. For the last seven days, it was given in doses of 500 mg. four times per day. She also received isoproterenol (Isuprel) hydrochloride sublingually for seven days. Large doses of antibiotics were administered for two weeks after the resuscitation.

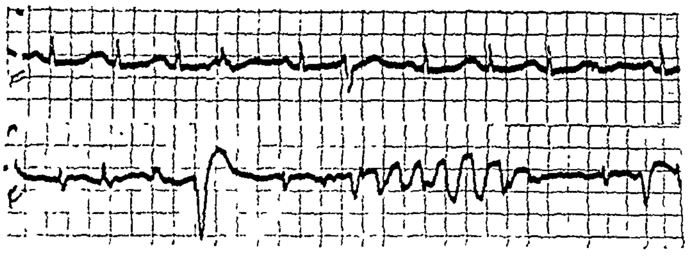

Fig. 3.—*Top*, electrocardiogram (lead aVF) taken on Sept. 24, 1955, 24 hours after defibrillation of the heart; sinus tachycardia (rate 100), frequent multifocal ventricular premature beats, and quinidine effect are present. *Bottom*, electrocardiogram (lead aVF) taken on Sept. 28, 1955, 5 days after defibrillation, showing ventricular premature beats and paroxysmal ventricular tachycardia.

The patient's recovery was uneventful except for minor complications. The chest incision healed per primum. There was evidence of a mild pericarditis during the second postoperative week. There was also thrombophlebitis of the legs. This was treated satisfactorily with anticoagulants. The patient's general condition gradually improved. There were progressive changes in the electrocardiograms, with the eventual appearance of a regular sinus rhythm (fig. 3 and 4). Five weeks after the reversal of a fatal arrhythmia, the patient walked out of the hospital. She had no evidence of brain damage, and her heart was beating regularly.

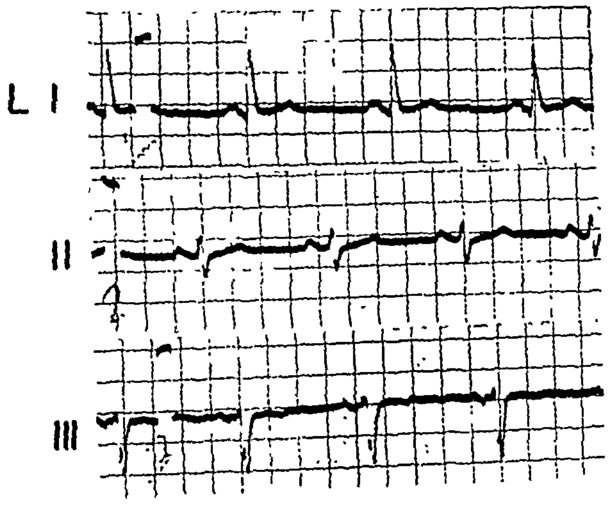

Fig. 4.—Electrocardiogram taken on Oct. 17, 1955, 24 days after defibrillation, showing sinus bradycardia and left ventricular hypertrophy.

Requirements for Successful Resuscitation

In order to carry out a successful resuscitation, several things are necessary. The first is a proper understanding of the resuscitative technique.[3] This understanding can be achieved only when the procedure is divided into its two separate and distinct steps. The first step is to reestablish the oxygen system. This means that oxygen must be delivered to the lungs (this is done best through an endotracheal tube attached to a rubber bag full of oxygen) and that the oxygenated blood must be circulated by hand massage of the heart. This first step is the emergency act and must be accomplished quickly in order to preserve the viability of the sensitive brain cells. The equipment needed to perform this first step is simple and easily obtainable. An instrument to open the chest and some method to deliver oxygen to the lungs are all that is necessary. When the oxygen system has been reestablished, the emergency is over. The second step in the resuscitation may be performed in a leisurely fashion.

The second step in resuscitation is the restoration of the coordinated heartbeat. If the heart is in asystole, this may be readily accomplished by compression alone or by intracardiac administration of epinephrine combined with hand massage of the heart. If fibrillation is occurring, the second step may be more difficult. A defibrillator is necessary to deliver the proper electric shock to the heart.[4] In addition, various drugs may also be needed.

Besides a thorough understanding of the resuscitative technique, several other things are needed. A rib spreader should be used to keep the ribs away from the wrist of the surgeon in order to prevent excessive fatigue during the cardiac massage. The necessity of a defibrillator has been previously mentioned. Sterile linen is needed to drape the chest incision. Absorbable sutures and surgical instruments are needed to close the chest. At the present time, the operating room is the only place where all of this equipment is readily available.

Future of Resuscitation

It is obvious that new possibilities for successful resuscitation are being created. In both of the successful cases in this hospital, the previous general attitude would probably have been to discourage the attempt at resuscitation. There is scarcely a cardiologist who would attempt it in the presence of coronary artery disease. The same can be said of the case reported here. But they were successful, and experience must point the way for future action. It is hardly possible to discuss the applicability of resuscitation. There are no rigid definitions of conditions that must prevail in order to attempt resuscitation. There are instances in which success in resuscitation is impossible, and in some cases success is even undesirable. Such cases would be those in which irreversible brain damage may have occurred or those in which incurable disease may be present.

Whether resuscitation by direct handling of the heart can be extended beyond the hospital is a problem that will receive future consideration. It may even become a debatable subject. There can be but little doubt that the "death factor" may be reversible in many people who fall over dead with a fatal heart attack. In many of these cases, the heart is an anatomically good organ that ought to be able to continue beating. In these cases, the coordinated beat is destroyed by electric currents that accumulate in the heart and, when strong enough, cause fibrillation. Under favorable circumstances, the heart could be given a "second chance to beat" and some of these people might be saved. Several questions should be asked. How often is successful resuscitation possible in patients with fatal heart attacks? In what other conditions is success possible? In what conditions should resuscitation not be attempted? What are the requirements for success? Can these requirements be met outside the hospital? Can the procedure be simplified so that it becomes unnecessary to open the chest? What safeguards must be taken to prevent unjustified resuscitative attempts? What will be the situation of resuscitation in 25 years? These questions deserve consideration. Correct answers to these questions are not possible at the present time. In order to determine these answers, further experiences are necessary.

2065 Adelbert Rd. (16) (Dr. Mozen).

Dr. Claude S. Beck helped during the resuscitation and in the preparation of this report.
Dr. Herman K. Hellerstein analyzed the electrocardiograms.

SELENIUM SULFIDE IN TREATMENT OF PITYRIASIS VERSICOLOR

Harry M. Robinson Jr., M.D.
and
Stanley N. Yaffe, M.D., Baltimore

Pityriasis versicolor is a benign, noncontagious, superficial fungus infection of the skin caused by Malassezia furfur. The characteristic macular eruption usually appears on the upper trunk and shoulders, although it may involve other parts of the body. The color of the lesions may be pink, fawn colored, light

---

From the Division of Dermatology, Department of Medicine, School of Medicine, University of Maryland and the University Hospital.

brown, or whitish. Both discrete and confluent areas are commonly seen in the same patients. Gentle scraping of the surface produces a fine furfuraceous scale from which the diagnosis of pityriasis versicolor is established by demonstration of the presence of filaments and spores of Malassezia furfur in the scrapings. Microscopic identification of the causative organism is accomplished by examination of a wet potassium hydroxide perparation or by the use of the ink-potassium hydroxide stain.[1] The condition is most commonly observed during the summer months, but many cases are also seen during the cooler months of the year. Subjective symptoms are usually absent, but some patients complain of mild itching, particularly when profuse sweating occurs.

In spite of the fact that this condition was first described over 100 years ago, no regimen of therapy has been devised to provide uniformly satisfactory results. Among those remedies that have been employed with some success in the treatment of pityriasis versicolor are sulfur, salicylic acid, a combination of sulfur and salicylic acid, resorcinol (resorcin) alone and in combination with other drugs, naphthol, saturated solution of sodium thiosulfate (sodium hyposulfite) benzoic and salicylic acid (Whitfield's) ointment, tincture of iodine, chrysarobin ointment, mercury bichloride, sulfuric acid, mild mercurous chloride (calomel) ointment, pyrogallol, tar, and turpentine. These drugs or combinations of drugs have been partially effective, ineffective, or sensitizing in the vast majority of patients treated.

Method of Study

Preparation Used.—A water-miscible ointment base containing a 1% solution of selenium sulfide was dispensed in 1-oz. tubes to the patients under treatment. The preparation has a pale orange-yellow color. No discoloration of the treated area was evident when a thin film of the ointment was applied to the skin. The application of a 1% solution of selenium sulfide cream to the skin is not productive of any unpleasant subjective symptoms.

Case Selection.—The patients included in this study were all ambulatory and were obtained from the dermatology outpatient department of the University Hospital and from our private practices. There were 9 Negro males, 4 Negro females, 7 white females, and 12 white males included in this study, a total of 32 patients who ranged in age from 13 to 57 years. In all instances the diagnosis of pityriasis versicolor was established by a microscopic study of ink-potassium hydroxide preparations.

Treatment Routine.—All patients were advised to initiate treatment by taking a shower with warm soapy water, thoroughly rinsing the skin to remove all traces of the soap, and then patting the skin dry with a towel. Towels and all clothing worn next to the skin were to be thoroughly laundered and dried before reusing them. Following the bath, the patient was instructed to lightly massage a thin film of the ointment into all of the involved areas twice daily. The bath is to be repeated every three days. At the end of one week of this treatment, the patient reported to the physician for further observation. Instructions were given each patient to have some assistance at home in applying the medicament so that all of the areas would be treated. The routine was repeated for a second week and then discontinued.

Results of Treatment

The results reported in this study represent a minimum post-treatment observation period of one year in all of these patients. Two of the Negro males and two of the Negro females who obtained an initial satisfactory result did not report for the more recent post-treatment examinations; however, at the end of a three-month period all of these patients had retained satisfactory results. Involution of lesions with no recurrence was observed in all of the other patients treated. No adverse reactions were encountered.

Summary and Conclusions

Thirty-two patients with pityriasis versicolor were treated with a 1% solution of selenium sulfide in a water-miscible ointment base. Involution of lesions occurred in 28 patients, and no recurrence of the eruption was noted after one year. These results indicate that a 1% solution of selenium sulfide ointment is an efficacious method of treatment for pityriasis versicolor. It is clean, nonirritating, and effective. No adverse reactions were encountered in this study.

Lombard and Green streets (1) (Dr. Robinson).

This study was supported by a grant-in-aid from the Abbott Laboratories, North Chicago, Ill. The selenium sulfide ointment was furnished by Dr. George Berryman of Abbott Laboratories.

Diabetic Coma—Simple Test for Acetone.—The trend of diagnostic procedures and those to aid in guiding therapy is toward greater complexity. There is a tendency also to disregard simple measures in favor of the more complex even though the simple measure may be more widely applicable and foolproof. A simple test for acetone in the plasma as a diagnostic procedure in detecting diabetic coma and as a measure in guiding the therapy is a case in point. The test is easy to perform, requires a minimum amount of apparatus, gives easily reproducible results and is of assistance in assessing both the severity of the ketosis and the response to therapy. Hence, it is a valuable guide to insulin therapy. Determinations of the blood sugar and carbon dioxide combining power are not always reliable; they may needlessly sacrifice precious time, and under some circumstances they do not reflect either the degree of ketosis or the response to therapy. Also, the degree of ketonuria is likely to mislead. It is not a sufficient guide since strongly positive reactions for ketonuria may continue to occur during the course of treatment until the blood is almost completely cleared of excess ketone bodies. If ketonuria were used as a guide, overtreatment with insulin would be probable. However, an easy adaptation of the routine test for acetone in the urine permits this test to be used on the blood plasma to detect the presence of and degree of ketonemia. This information is of utmost value.—Charles T. Lee and Garfield G. Duncan, Diabetic Coma: The Value of a Simple Test for Acetone in the Plasma—An Aid to Diagnosis and Treatment, *Metabolism—Clinical and Experimental,* March, 1956.

COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

H. D. Kautz, M.D., *Secretary.*

Poliomyelitis Vaccine.—A formaldehyde-inactivated vaccine containing approximately equal parts of aqueous suspensions of individually tissue-cultured type 1, type 2, and type 3 strains of poliomyelitis virus approved by the National Institutes of Health. The vaccine is tested for antigenic potency and for nonviability of component viruses in accordance with requirements promulgated by the National Institutes of Health.

Actions and Uses.—Poliomyelitis vaccine is used to induce artificial active immunity against paralytic poliomyelitis on the basis of its ability to stimulate the production of protective levels of antibodies in susceptible animals and in man. Observations on the protective effect of the vaccine as currently prepared are thus far inadequate to make it possible to reach final conclusions regarding the extent or duration of immunity that can be expected from its use. Its protective effect against nonparalytic forms of poliomyelitis infection and its influence upon the subsequent acquisition of natural immunity to the disease also have not been elucidated. Prior clinical trial with a similar preparation in school children of the most susceptible age group and epidemiological observations on the effect of the 1955 preparations suggest that the vaccine is capable of reducing the incidence of paralytic poliomyelitis by approximately 60 to 80%.

Poliomyelitis vaccine is as safe and as effective as can reasonably be expected. If possible, it is advisable to complete inoculations prior to the expected seasonal increase in the incidence of the disease. The presence of acute poliomyelitis in a community is not considered a contraindication to use of the vaccine in presumably unexposed but susceptible individuals; however, on the basis of present knowledge, it seems inadvisable to inoculate family contacts. Experience so far has not indicated that there is a provocative effect from inoculation with the vaccine.

Poliomyelitis vaccine should be employed with the usual precautions for vaccines in general. Local and systemic reactions after inoculation of the vaccine generally are mild and infrequent. General malaise and low-grade fever of short duration may be observed occasionally. The presence of small amounts of penicillin and streptomycin in the vaccine has not been associated with severe allergic reactions, except possibly in rare instances. So far, allergic reactions have been of a minor nature, and even inoculated subjects with known sensitivity to these antibiotics usually have not reacted adversely. In highly allergic persons, a test dose of the vaccine may be injected intradermally so that the effect can be observed before administration of the usual dose is attempted. The elimination of penicillin and streptomycin or its derivatives from the current preparation is advised by some authorities to eliminate the possibility that its use may sensitize some individuals; others feel that the amounts present in the vaccine are too small to be of significance and are no greater than the amounts found in milk from cows fed with antibiotics. The theoretical possibilities that the vaccine might be capable of inducing the formation of harmful Rh, kidney tissue, and animal serum antibodies so far have not been realized. The vaccine also has not been associated with other toxic reactions or neurological sequelae such as polyneuritis, radiculitis, and encephalopathy. While these are theoretically possible, poliomyelitis vaccine contains less protein than other vaccines in use and is not considered to involve any greater potential risk from this standpoint.

It should be apparent from the relatively short period of time over which the vaccine has been developed and used, as compared to established immunologic agents effective in the prevention of other infections, that its ultimate usefulness can be determined only after longer experience has been gained. Physicians and health officers should be alert to the need for confirmatory laboratory findings in the diagnosis of doubtful cases of poliomyelitis to insure accurate reporting of cases and correct interpretation of the effect of the vaccine. Careful observations of all previously inoculated subjects will speed the accumulation of knowledge essential for the further evaluation of the vaccine. These might well include records of lot numbers of the vaccine used, sites of injection employed, the exact course of weakness or paralysis, and other details of confirmatory findings should poliomyelitis occur in inoculated subjects.

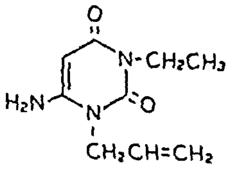
Dosage.—Poliomyelitis vaccine is injected subcutaneously or intramuscularly. Intradermal injection has not been sufficiently studied to justify that method of inoculation. Primary vaccination as currently suggested consists of two 1-cc. doses spaced at an interval of two or preferably four to six weeks and a third dose of 1 cc. not less than seven months after the second. Until more is known about the duration of the effect of the vaccine, the need for follow-up inoculations cannot be definitely determined.

The vaccine should be stored at a temperature between 2 and 10 C, preferably at 2 C, but should not be allowed to freeze. Changes in color of the vaccine under these conditions do not appear to alter its initial potency and safety. It should not be used if there is any evidence of turbidity.

Preparations for use as stated for the foregoing drug are marketed under the following name: Poliomyelitis Vaccine.

Eli Lilly and Company; Pitman-Moore Company, Division of Allied Laboratories, Inc.; Merck Sharp & Dohme, Division of Merck & Co., Inc.; Wyeth Laboratories, Division of American Home Products Corporation; Public Health Service, U. S. Department of Health, Education and Welfare; Dr. Jonas E. Salk; and Dr. Herbert Ratner cooperated by furnishing scientific data to aid in the evaluation of poliomyelitis vaccine.

Aminometradine.—1-Allyl-3-ethyl-6-aminotetrahydropyrimidinedione.—The structural formula of aminometradine may be represented as follows:



Actions and Uses.—Aminometradine, a synthetic uracil derivative, produces an increased flow of urine after oral administration. Its precise mode of action is not clear but is believed to be that of inhibiting the reabsorption of sodium ions by the renal tubule; potassium excretion is slight and variable. The drug does not affect carbonic anhydrase or succinic dehydrogenase and appears to have no significant effects on renal blood flow or glomerular filtration rate. In contrast to acetazolamide or the mercurial diuretics, aminometradine does not alter urinary pH nor does it cause significant changes in the systemic acid-base balance. Like acetazolamide and the xanthines, however, the drug has only minimal diuretic effects in normal, nonedematous individuals.

Aminometradine is an effective agent for the treatment of edema in patients with congestive heart failure. In mild to moderate cases, the drug may be used to initiate diuresis and subsequently to maintain an edema-free state. It is sometimes effective in producing diuresis in these patients when the organic mercurials fail. Conversely, other patients may respond well to the mercurials but not to aminometradine. There is suggestive evidence that the drug is most effective in patients with elevated serum sodium levels; its judicious use has sometimes reduced or eliminated entirely the need for mercurial diuretics.

Patients with severe cardiac decompensation and tending ascites, pulmonary edema, orthopnea, or dyspnea usually do not respond well to initial therapy with aminometradine. In such cases, rapid mobilization of edema fluid can best be achieved by paracentesis and/or administration of the mercurials. Once the acute congestive failure has been compensated, however, it is frequently possible to keep such patients in an edema-free state by the administration of maintenance doses of aminometradine. Regardless of the severity of congestive heart failure, the diuretic should be administered as an adjunct to and not as a substitute for other forms of therapy such as cardiac glycosides and a low-sodium diet.

Although the most satisfactory results with aminometradine have occurred in patients with congestive heart failure, the drug has also been of value in certain other conditions characterized by edema. Thus, in some patients with cirrhosis of the liver or the nephrotic syndrome, its administration may produce a moderate diuresis. In some patients with cirrhosis, this may be sufficient to eliminate or at least curtail the need for mercurials. There is also some preliminary evidence that aminometradine may be useful for the treatment of edema associated with the administration of adrenal cortical steroids and phenylbutazone. Sufficient valid evidence is lacking, however, of the drug's usefulness in toxemia of pregnancy or premenstrual tension.

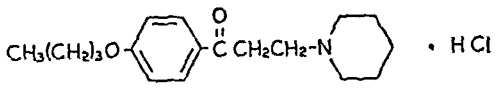
Aminometradine has not so far been reported as causing serious toxic effects, and there are no known contraindications to its use. Although its metabolic fate is imperfectly understood, it appears to be a relatively safe agent for use in the presence of severe cardiac, hepatic, or renal damage. Minor side-effects are common; nausea and vomiting occur in about 20 to 30% of the patients to whom it is administered. Rarely, these may be of sufficient severity to necessitate discontinuation of therapy or reduction of dosage below effective levels. Other side-effects such as anorexia, headache, and diarrhea are infrequent and mild.

Dosage.—Aminometradine is administered orally. Dosage must be determined individually according to the severity of the edema. For the initiation of diuresis or for maintenance therapy in adults and children, the daily requirement ranges from 0.2 to 0.8 gm. In an effort to minimize gastric disturbances, this amount is administered on an interrupted dosage schedule. This may be accomplished either by administration of 0.2 to 0.8 gm. every other day in divided doses during meals or by administration of this amount in divided dosage during meals for three consecutive days and then complete omission on the following four days.

Preparations for use as stated for the foregoing drug are marketed under the following name: Mictine.

G. D. Searle & Co. cooperated by furnishing scientific data to aid in the evaluation of aminometradine.

Dyclonine Hydrochloride.—4′-Butoxy-3-piperidinopropiophenone hydrochloride.—The structural formula of dyclonine hydrochloride may be represented as follows:



Actions and Uses.—Dyclonine hydrochloride, a topical anesthetic agent, differs from most drugs of this pharmacological class in that it does not contain the ester or amide linkage typical of compounds such as procaine. Its systemic toxicity is low; in man and experimental animals, relatively large oral or intravenous doses produce little alteration in respiration, blood pressure, or pulse. No changes referable to inhibition of the parasympathetic nervous system are discernible. The drug also has antimicrobial properties; however, since this action has been established only by in vitro tests, its possible clinical significance is undetermined at present.

Dyclonine hydrochloride is usually an effective anesthetic agent when applied topically to the skin or mucous membranes. The onset of action is rapid, and the intensity and duration of anesthesia compares favorably to that of compounds of the procaine type. The drug is useful in dermatological practice for the treatment of skin conditions in which relief of pain and pruritus is desired. It also may be used for the symptomatic treatment of minor burns and minor trauma, for relief of postoperative discomfort such as occurs after episiotomy, and for symptomatic management of pruritus ani or vulvae. The drug also has been used to anesthetize mucous membranes prior to instrumentation, as for example, before laryngoscopy, bronchoscopy, esophagoscopy, proctoscopy, and systoscopy. When instilled into the conjunctiva, it affords anesthesia without producing miosis or mydriasis.

Although longer clinical experience is necessary to determine its ultimate potentiality as an allergen, at present there are no reports of true sensitization or hypersensitivity to dyclonine hydrochloride. Likewise, the drug has not produced cross sensitization with other local anesthetic agents, a characteristic that may be the result of the differences in chemical structure. To date, irritation at the site of local application has been the only significant side-effect to its administration. Despite its low systemic toxicity, sufficient evidence is at hand to justify its use only by topical application.

Dosage.—Dyclonine hydrochloride is administered topically in a 1% concentration in a vanishing cream base or as a 0.5% aqueous solution. It is applied as necessary to the skin or mucous membranes in amounts necessary to cover the painful or pruritic surfaces.

Preparations for use as stated for the foregoing drug are marketed under the following name. Dyclone.

Pitman-Moore Company, Division of Allied Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of dyclonine hydrochloride.

Intravenous Use of Gitalin (Amorphous)

The Council has evaluated the usefulness of gitalin (amorphous) by the intravenous route. On the basis of currently available evidence, the Council concluded that the intravenous injection of this glycoside preparation is useful for the rapid digitalization of adult patients in whom the oral route is not feasible, especially those with acute, congestive cardiac decompensation. The average initial dose by this route is 2.5 mg. twice in 24 hours. The usual total digitalizing dose is about 5 to 6 mg. After full digitalization, when maintenance by the parenteral route is indicated, intravenous administration of doses as high as 2.5 mg. twice weekly have been used, although intravenous injection of 0.5 mg. daily may be adequate. However, oral maintenance therapy of 0.5 mg. daily should be substituted as soon as possible. Intravenous administration should be done with caution and in reduced dosage if the patient has received other digitalis drugs within the previous 2 weeks.

The Council voted to amend New and Nonofficial Remedies accordingly to describe this additional route of administration.

White Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of the intravenous use of gitalin (amorphous).

Use of Immune Globulins for the Treatment of Agammaglobulinemia or Hypogammaglobulinemia

The Council was requested to evaluate the usefulness of poliomyelitis immune globulin (human) for the treatment of agammaglobulinemia or hypogammaglobulinemia. This syndrome, which may occur in both adults and children, is characterized by an acquired or congenital absence or deficiency of gamma globulin, the serum fraction that contains most of the antibodies. A diagnosis of agammaglobulinemia or hypogammaglobulinemia may be entertained on the basis of repeated bacterial infections, the absence of isohemagglutinins, and a comparative inability of antibiotics to combat these infections. Confirmation may be obtained by determination of the serum gamma globulin level. In such cases it appears logical, therefore, to attempt to control clinical symptoms by the administration of compatible, but exogenous, immune gamma globulin. On the basis of currently available evidence, the Council concluded that routine "replacement" therapy with poliomyelitis immune globulin (human) is useful for the treatment of this syndrome. The immunity thus provided is temporary and passive: continued protection depends on routine and regular administration of the immune globulin. Although data were considered on poliomyelitis immune globulin (human) only, the Council was aware that the older preparation, immune serum globulin, is equally effective for the treatment of patients with this condition. The Council further concluded that, insofar as the other serum antibodies are concerned. poliomyelitis immune globulin (human) is equivalent to immune serum globulin and that both preparations can be used interchangeably in patients with agammaglobulinemia or hypogammaglobulinemia. For this purpose the preparations are administered by deep intramuscular injection, preferably in the gluteus. No arbitrary dosage schedule has as yet been determined. Judicious management of dosage should be on an individual basis with an attempt to determine for each patient the lowest dose required for his protection. Likewise, the interval between injections must be individually determined. Factors such as the age and weight of the patient, his general state of health, and the bacterial and viral antigens to which he has been exposed should be taken into consideration. As a general pattern, monthly injections of 30 to 50 cc. for adults and 20 to 40 cc. for children may be given; however, it is possible that doses much smaller than these may be adequate with less discomfort to the patient.

The Council voted to amend New and Nonofficial Remedies accordingly to describe the use of poliomyelitis immune globulin (human) and immune serum globulin for the treatment of agammaglobulinemia and hypogammaglobulinemia.

Merck Sharp & Dohme, Division of Merck & Co., Inc., cooperated by furnishing scientific data to aid in the evaluation of the usefulness of poliomyelitis immune globulin (human) for the treatment of agammaglobulinemia or hypogammaglobulinemia.

EPILEPSY AND THE EPILEPTIC

GUEST EDITORIAL

William G. Lennox, M.D.

The frontiers of epilepsy are many: the anatomy, physiology, and chemistry of the brain; psychology and psychiatry; pharmacology, sociology, and legal medicine; and the broad borderland of human relations. On each of these fronts some advance is being made. For example, the World Health Organization sponsored a six-day conference in London last October devoted to a discussion of juvenile epilepsy as a problem in public health. Broadly considered, any illness that affects a significant segment of the population, and that may yield to well-directed effort, deserves that resources be pooled for its prevention and control. In the past, public health efforts have been centered on the epidemiology and control of infectious disease. The phenomenal success that has resulted should release efforts for the control of other forms of serious illness. One of these, emphasized by the London conference, is epilepsy. This conference was attended by experts on the subject drawn from eight different countries. The findings will be issued from Geneva. Aside from recognition by the World Health Organization, three principal areas of progress may be outlined. The first, physiology, concerns epilepsy, the disorder. The second and third, therapeutics and social-psychological, concern the epileptic, the person.

The brain is the master organ of the body. Other organs may become diseased and the individual suffers; one disordered brain may disrupt a community, or nation. Yet, study and understanding of the brain has lagged far behind that of other organs. Its inaccessibility and complexity have awed the physician; the sad consequence of any dysfunction has frightened the people. How else can the public neglect of the brain as compared with, for example, the heart or even the joints be explained?

Twenty-seven years ago Berger breached the bony bastion that surrounds the brain by demonstrating that its electrical potentials, when led off from the scalp, would write a record of cerebral activity. This discovery has released epilepsy from the crypt of the unknown. "Cryptogenic" is now an outmoded term. Epilepsy is simply a paroxysmal dysrhythmia of brain potentials. Unless complicated by some cerebral lesion, this dysrhythmia, epilepsy, is based on some peculiarity in the metabolism of brain cells. Hence, epilepsy is a metabolic disease, comparable, for example, to diabetes. The student of epilepsy is especially favored, because the brain-wave pattern, when not distorted by some acquired brain lesion, is a hereditary trait. One study includes electroencephalograms and intelligence tests of 225 twin pairs affected by seizures. The relative influence of heredity and of acquired conditions in the cause of seizures and of mental retardation is thereby weighed. Identical twins, without acquired brain injury, have a high concordance not only of epilepsy but of a certain type of seizure and of a certain pattern of electroencephalographic abnormality.

Epilepsy has been the chief beneficiary of electroencephalography, but the technique is now an important tool for that most important of all tasks, an understanding of the working of the human brain and, hopefully, how dysfunction may be corrected. Present interest in both epilepsy and the science of brain function centers in the temporal lobe and its communicating structures. Seizures indigenous to this area are varied and bizarre, causing hallucinations of smell or taste; peculiar dream-like states; vivid pseudomemory of places or events; and automatic behavior that ranges from the ludicrous to the antisocial, with amnesia for what occurred. A display of spikes in the electroencephalogram made during sleep points to the temporal lobe as the responsible area. Because associated seizures (broadly termed psychomotor) respond poorly to anticonvulsant drugs, excision of the epileptogenic area offers a possible means of drastic relief. A thoroughgoing analysis of present-day knowledge of the brain in relation to psychomotor epilepsy is being made by a panel of experts from various countries. These will meet successively in Marseilles and in Washington, D. C., and, finally, in 1957, will meet in Brussels. The last session will be with the international congress of the League Against Epilepsy, of which Prof. A. Earl Walker is president.

The key to the mechanism of uncomplicated epilepsy is marked neurochemistry, and not neuropathology or neurophysiology. Slices of the cortex of the human brain that emit seizure discharges have proved to be defective with respect to acetylcholine, glutamic acid, potassium, and energy systems. The addition of L-glutamine or L-asparagine to such slices corrects these defects. Although in vitro studies require clinical confirmation, observations such as these may be a crack in the door that hides the secret of abnormal neuronal function in epilepsy.

The second area of progress, therapeutics, is the most important for the immediate prospects of the person subject to seizures. Success has been commensurate with that attained with the antibiotics against infections. Physicians now have half a dozen drugs variously effective in the control of convulsions and psychomotor seizures and another half-dozen useful in control of the petit mal seizures of childhood. By skillful use of medicines, alone or in combination, the majority of patients can be relieved of a majority of

---

From the Seizure Division of the Children's Medical Center, Boston 15.

their seizures and a substantial number indefinitely rid of them. Nor is therapy only with drugs. With the aid of electrodes planted on, or even below, the cortex, epileptogenic foci, especially those from the brain surface, can be removed with minimal impairment of the functioning of body or mind.

The third area of treatment, social-psychological, is as important to the patient as the other two, but progress has been less real. Because of the stigma of seizures, the epileptic, though rid of his attacks, may encounter social and psychological barriers to satisfactory living. Among repressive laws, those that bar marriage are most archaic. Largely through the efforts of doctors, laws that forbid marriage have been recently rescinded or amended in 3 states, but they remain in 16.

A second and more controversial question concerns the licensing of persons to drive motor vehicles. Provisions vary greatly from state to state. For some, epilepsy is a reportable disease. Some states rule against use of anticonvulsant medication. The application blanks of most states ask specifically about epilepsy, but avoid mention of the use of alcohol. How do the fatality records compare? In Massachusetts each case is judged on its individual merits, with heavy dependence on the recommendation of physicians experienced in the treatment of epilepsy. During the last three years epilepsy caused not a single death and less than 1% of all accidents, whereas fatalities because of alcohol numbered 265. A number of factors enter into a physician's recommendation: the interval of time since the last seizure (at least 18 months); the age at onset of seizures and the former type and frequency of these; the constancy and the duration of the warning aura; the time of seizures, whether they occur only at night; the degree of abnormality of the electroencephalogram; the person's veracity and sobriety; the person's adherance to prescribed treatment; and the amount and kind of the expected driving.

A third and even larger problem is that of employment. Epileptics have been excluded from employment because of general prejudice and fear of a high accident rate, a fear that is unjustified if there is proper job placement. But how is proper job placement possible if admission of a history of seizures is an automatic bar to employment? Enactment of a workable second injury clause would seem to lessen this handicap.

With the aid of a grant from the U. S. Public Health Service, the physicians' League Against Epilepsy has sponsored a survey of state laws with respect to marriage, drivers' licenses, and employment of epileptics. Roscoe L. Barrow, dean of the University of Cincinnati School of Law, and Dr. Howard D. Fabing have written a book entitled "Epilepsy and the Law."[1] Increased public understanding, acceptance, and active assistance of the epileptic proceeds at too slow a pace. As emphasized by the current motion picture "The Dark Wave," patients or their relatives are loath to join public efforts in their own behalf. A glowing exception is the account of her own illness by the English author Margiad Evans.[2] In terms of number of dollars or hours expended, therapeutic results are far greater for epilepsy than for most neurological disorders. Yet, public interest and support of the large body of epileptics has been relatively meager. Through the journal *Epilepsia* and a growing number of medical articles and books, clinicians have access to present-day knowledge of epilepsy and of the means of its control. The physician should also help to remove the attendant social and psychological impediments to useful living. The epileptic is not a muscle-nerve preparation, dissected out of a frog for experiments in pharmacology. Prescription of medicine is but half the treatment. Laboratory and pharmaceutical research have lifted epilepsy out of the dark ages. With the practitioner of medicine rests the opportunity and the responsibility for quickened progress in the area of human relations.

W. M. A. MEETING IN CUBA

Within a matter of weeks physicians from over the world will meet in Havana, Cuba, to attend the 10th Annual Assembly of the World Medical Association. Those who know this delightful Caribbean country will need no second invitation to plan for the pleasures that accompany meetings of the World Medical Association, and those who want firsthand accounts of what is transpiring in medical practice in other countries can find no better meeting to satisfy their curiosity. Dr. Louis H. Bauer, secretary general of the association, has mailed to delegates from national medical associations the program for the meeting. It offers a diet for all doctors genuinely interested in medical practice. Those physicians who have not completed plans for attendance should do so now, before it is too late. Details will be supplied gladly by Dr. Louis H. Bauer, Secretary General, World Medical Association, 10 Columbus Circle, New York 19.

The date of the meeting is October 9-15. Included in the program for the Assembly are a variety of topics on problems facing physicians and their patients and the experiences of doctors from among the 50 or more national medical associations that make up the World Medical Association. Also included is a session of scientific papers to be formally presented by leading physicians in Cuba. Of interest to medical editors will be the half-day program featuring Pan-American medical publication problems with discussants from Germany, Japan, Luxembourg, Finland, and elsewhere. This, however, only suggests the breadth of the topics that will be explored, as the thoughts expressed in the discussions that follow the reports often are as revealing as the reports.

Wives of physicians attending the Assembly will be pleased with the social and entertainment program arranged for their enjoyment. As for the renowned hospitality of the physicians of Cuba, words are not necessary for those who have been guests of Cuban physicians. Add thoughts of this to the climate, the beaches, the countryside, and other attractions and the future is appealing for the visitors to this 10th annual meeting of the World Medical Association.

ORGANIZATION SECTION

JOURNAL INDEX

The index to volume 161 of The Journal appears in this issue. Those who wish extra copies of the index may receive them without charge on request to the Order Department, American Medical Association, 535 N. Dearborn St., Chicago 10.

TWO ADDITIONS TO A. M. A. STAFF

Philip L. White, B.S., M.S., D.Sc., who has been with the department of nutrition of the Harvard School of Public Health for a number of years, is the new Secretary of the A. M. A. Council on Foods and Nutrition, and Wallace Wesley, B.Ed., M.S., Hs.D., has been appointed consultant in health and fitness in the A. M. A. Bureau of Health Education.

Dr. White will take over his new job on Sept. 1. In 1951, he served as nutrition advisor to the department of nutrition of the Peruvian Ministry of Public Health. His publications in this field include reports etary surveys conducted on the coast, in the e, and in the high sierras of Peru; a table of the position of Peruvian foods; a study of the necessity amino acid supplementation of all-vegetable diets in human nutrition; reports on the nutritive value of some Peruvian seed products; and the iron requirement of children infested with intestinal parasites. On returning to Harvard, he did research in experimental atherosclerosis and on protein metabolism. Last winter, Dr. White was a member of the U. S. team that conducted a nutrition survey for the armed forces of Iran.

Miss Wesley, who will work with Fred V. Hein and Donald A. Dukelow in furtherance of the health of the school-aged child, began her new duties on Aug. 1. She has taught health on the elementary, high school, and college levels and general science and physical education in the public schools. Miss Wesley is a registered physical therapist, with hospital experience.

A. M. A. PAMPHLET SALES

More than 396,000 health education pamphlets were sold by the A. M. A.'s Bureau of Health Education during the 12 months ending June 30, 1956. These sales indicate a widespread use by nonmedical persons of materials prepared and sold by the A. M. A. They also furnish an index of the health interests of a considerable cross section of the American people. The largest single group of pamphlets sold was 69,000 on the health of the school-age child. Mental health pamphlets sold totaled 35,574, those on accidents and first aid 25,575, teeth 18,674, nutrition and diet 18,000, maternal health 17,296, physical fitness 15,319, and heart and circulation 12,400. Most of the pamphlets are reprinted from *Today's Health.*

CRASH INJURY FILM

The general public will learn about the role played by physicians in prevention of auto crash injuries in a new motion picture just completed by the American Medical Association in cooperation with the Ford Motor Company. The 15-minute film, entitled "On Impact," incorporates information on auto crash injuries presented at the A. M. A.'s Annual Meeting in June and an analysis of recent safety improvements in motor vehicle design. Featured in "On Impact" are Dr. Fletcher D. Woodward of the University of Virginia School of Medicine, Chairman of the A. M. A.'s Committee on Medical Aspects of Automobile Injuries and Deaths, and John O. Moore of Cornell University Medical College. "On Impact" will be released to television stations across the nation, for use on public service time, on Sept. 1. After that date, county and state medical societies and their auxiliaries can obtain prints from the A. M. A.'s TV Film Library for showing at either professional or public meetings.

FEDERAL MEDICAL LEGISLATION*

Second Session, 84th Congress

United States Nursing Academy

Senator Ives (R., N. Y.), in S. J. Res. 188, proposes to establish in the Department of Defense an Academy of Nursing to train young women in nursing for the armed forces. The Secretary of Defense would select one "cadette" annually for each member of Congress from among candidates submitted by the member. The President would appoint 30 "cadettes." Graduates of the academy would have to agree to serve for not less than three consecutive years in the armed forces. This measure was referred to the Committee on the Armed Services.

---

*From the Washington Office of the American Medical Association.

Poliomyelitis Vaccine Liability

Senator Welker (R., Idaho), in S. 4168, would "authorize the payment of compensation for certain losses suffered as the result of the outbreak of polio following the early use of poliomyelitis vaccine" if contracted "(1) prior to June 1, 1955, and within thirty days after receiving one or more injections of poliomyelitis vaccine, or (2) as the direct result of exposure to one or more individuals who contracted poliomyelitis under the circumstances specified in clause (1)." This measure was referred to the Committee on the Judiciary.

Health Insurance Pooling

Senators Hill (D., Ala.) and Smith (R., N. J.), in S. 4172, and Congressmen Thompson (D., N. J.), in H. R. 12140, and Priest (D., Tenn.), in H. R. 12153, have introduced the administration's measure "to encourage the extension and improvement of voluntary health prepayment plans or policies by permitting pooling." The proposed plan is a redraft of the administration's reinsurance scheme. However, it abandons the proposal of a government-operated reinsurance fund and instead waives the federal and state antitrust laws so that small insurance companies (writing less than 1% of total health insurance) and voluntary plans may pool certain of their assets to guard against individual losses from experimental types of coverage. These measures were referred to the Committee on Labor and Public Welfare.

Scholarships for Postgraduate Education in Public Health

Senator Magnuson (D., Wash.), in S. 4208, proposes "to amend the Public Health Service Act to provide a program of scholarships for postgraduate education." The bill would authorize $250,000 annually for five years. The surgeon general of the Public Health Service would consult the National Advisory Health Council in determining the need for scholarships in each of the fields relating to public health. Awards would include the cost of tuition, books, equipment, and maintenance. This measure was referred to the Committee on Labor and Public Welfare.

State Committees on Higher Education

Senators Smith (R., N. J.) and Hill (D., Ala.), in S. 4211, and Congressman Elliott (D., Ala.), in H. R. 12237, propose "to encourage and assist the States in the establishment of State committees on education beyond the high school." The bills would authorize $800,000 to be allotted to the states for the purpose of calling together educators and other interested persons to consider educational problems beyond high school and to make appropriate recommendations. Appropriation authorization would also be provided for the expenses of the President's Committee Beyond High School. This measure was passed by both Senate and House and became Public Law 813.

Presumption of Service Connection for Multiple Sclerosis

Senator Morse (D., Ore.), in S. 4286, proposes to increase from two to three years the period after discharge from active military service during which multiple sclerosis of 10% or of more degrees is considered service-connected. This measure was referred to the Finance Committee.

Narcotics Addict Treatment and Rehabilitation Act

Senators Eastland (D., Miss.), Daniels (D., Texas), Welker (R., Idaho), and Butler (R., Md.) propose, in S. 4296, "to authorize the care and treatment at facilities of the Public Health Service of narcotic addicts committed by State courts and other authorities." Any narcotics addict making application voluntarily for treatment in federal hospitals for his addiction would make application to the U. S. District Court for commitment. Commitment would be made for a period of time estimated by medical authorities as sufficient for the addict to receive maximum benefits from the treatment. Addicts would not be admitted if they had been treated on three or more occasions in federal hospitals and had again lapsed to the use of drugs. The voluntary patient could be required to pay for care and subsistence; otherwise, the Public Health Service would bear the expense. The surgeon general would also accept, treat, and forcibly detain narcotics addicts committed by state courts. The cost of providing care would be a charge upon the state whose courts committed the addict. This measure was referred to the Committee on Labor and Public Welfare.

Tax Deduction for Contributions to Medical Research

Congressmen Keogh (D., N. Y.), in H. R. 12151, and Curtis (R., Mo.), in H. R. 12152, have introduced identical measures to permit contributions to medical research organizations as a deduction in computing personal income tax. The present law allows deduction of contributions to hospitals up to 10% of the taxpayer's adjusted gross income in addition to 20% allowance for contributions to other recognized charitable organizations. The proposed bill would permit inclusion of contributions to "medical research organizations directly engaged in the continuous active conduct of medical research in conjunction with a hospital" as well as to hospitals. These measures were referred to the Ways and Means Committee.

Grants for Studies and Projects for Aged

Congressmen Williams (D., N. J.), in H. R. 12154, and Flood (D., Pa.), in H. R. 12260, have introduced measures identical to S. 4117, introduced by Senators Hill (D., Ala.) and Kennedy (D., Mass.) and previously reported. These bills "would authorize Federal grants to assist in the development and operation of studies and projects to help older persons." Eight similar measures previously reported would establish a Bureau of Older Persons in the Department of Health, Education, and Welfare, but this is not provided in the William, Flood, or Hill-Kennedy bills. The House measures were referred to the Committee on Education and Labor.

Extension of Vocational Rehabilitation Act Amendment

Congressman Elliott (D., Ala.), in H. R. 12161, has introduced a measure identical to S. 3875, introduced by Senator Magnuson (D., Wash.), and H. R. 11369, introduced by Congressman Dempsey (D., N. Mex.), previously reported. These measures would extend until June 30, 1957, that part of the Vocational Rehabilitation Act that pertains to grants and other nonprofit organizations and agencies that are "planning, preparing for, and initiating . . . substantial nationwide expansion of vocational rehabilitation programs in the States." The House bills were handled by the Committee on Education and Labor and the Senate bill by the Labor and Public Welfare Committee. The Senate bill became Public Law 937.

Medical Care for Foreign Service Employees Overseas

Senator George (D., Ga.) has introduced, in S. 3481, an administration measure to make foreign service more attractive for citizens of the United States. The provisions of the bill include medical benefits for certain government employees while they are stationed abroad. The covered employees would be State Department Foreign Service officers and employees and employees of the International Cooperation Administration, the U. S. Information Agency, and the Foreign Agricultural Service of the Department of Agriculture and their dependents. There are roughly 10,000 employees and 13,000 dependents in these groups. The government would assume responsibility for medical expenses within prescribed limits for illnesses or injuries incurred abroad when they are sufficiently serious to require hospitalization or similar care outside a hospital. For officers and employees the government would pay the full cost of treatment. For the employee's dependents the employee would be required to assume a part of the cost in each instance, and a maximum is placed upon the government's liability for financial help. The employee must assume up to $35 of the cost of treatment for his dependents for each illness, with the government assuming responsibility in excess of that amount but not in excess of 120 days of hospitalization or equivalent care for each illness or injury. The Secretary is given authority to pay transportation expenses involved in moving a dependent from a locality in which no suitable hospital or clinic exists to the nearest suitable hospital or clinic. Where hospitalization beyond 120 days is required, the Secretary may authorize continued payment when it is determined that the illness or injury is caused by the fact that the dependent is, or has been, located abroad. It is intended that regulations prescribed by the Secretary will exclude certain types of medical expense, such as optional plastic surgery, dental treatment, and normal maternity cases. Authority is given the Secretary to provide medical benefits through insurance or private health plans, if such methods are as good or as economical as direct payment by the government. The employment of a physician or other medical personnel is authorized in first-aid stations at posts where such is necessary. In cases where suitable government or private facilities already exist, the Secretary is not authorized to make such arrangements. It is thought that much of the care would be in U. S. government military medical facilities. This bill was referred to the Committee on Foreign Relations, where hearings were held for one day only. The bill was reported to the Senate and was passed by both houses to become Public Law 828.

Congressman Morrison (D., La.) in H. R. 12193, introduced a similar measure July 11 providing benefits for all United States citizens who are civilian government employees overseas, but hearings were not held. It is expected that a similar measure will be introduced early in the first session of the 85th Congress. The Morrison bill was referred to the Post Office and Civil Service Committee.

MEDICAL NEWS

CALIFORNIA

Lane Medical Lectures.—The 33rd course of Lane Medical Lectures will be delivered in Lane Hall, Stanford University School of Medicine (Sacramento Street near Webster, San Francisco), by Sir Charles Dodds, M.V.O., M.D., Ph.D., F.R.S., Courtauld Professor of Biochemistry, the Middlesex Hospital Medical School, London, England. The medical profession, students, teachers, and research workers in medicine and allied sciences are cordially invited to attend the series on "Biochemical Experiments in Endocrinology," which will be presented on the following dates at 8:15 p. m.:

Sept. 17, The Sex Hormones and the Development of the Synthetic Estrogens.
Sept. 18, Biological Action of the Synthetic Estrogens.
Sept. 19, Adrenal Secretion.
Sept. 20, Aldosterone.
Sept. 21, Pituitary Hormones.

Course in Medical Photography.—"Photography in Medical Practice and Research," a new postgraduate course, will be offered on Thursdays at 7:30 p. m., Sept. 20-Dec. 13, at the Medical Center of the University of California at Los Angeles to graduates of approved medical and dental schools and to research workers with consent of the course chairman. The fee is $35. Topics will include lighting, exposure, black-and-white film processing, the print, the motion picture camera, the reproduction of color, and other pertinent factors. Information and registration blanks may be obtained from Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, University of California, Los Angeles 24.

IOWA

Personal.—Dr. Robert C. Hardin, professor of internal medicine, State University of Iowa College of Medicine, Iowa City, has been given a training grant ($8,000 a year for five years) by the Institute of Arthritis and Metabolic Diseases, National Institutes of Health. Dr. Hardin's studies are on long-term follow-up of patients with diabetes.

General Practice Meeting.—The annual meeting of the Iowa Academy of General Practice will be held at the Hotel Savery in Des Moines, Sept. 13-14. Greetings will be extended Thursday morning by Dr. Walter D. Abbott, Des Moines, president, Polk County Medical Society. Presentations by out-of-state speakers will include:

Pain Patterns in Abdominal Disease. Disease of Left Colon, Lucian A. Smith, Rochester, Minn.
Diagnostic and Therapeutic Nuggets, Oscar F. Rosenow, Columbus, Ohio.
Use of Adrenal Steroids in Practice, H. Dalton Jenkins, Denver.
New Therapeutic Methods in Dermatology, Roy L. Kile, Cincinnati.
Diagnosis of Hypertension. Treatment of Hypertension, J. Harold Kotte, Cincinnati.
Diagnosis and Management in Peripheral Vascular Disease. Surgery of Blood Vessels (with movie), Fay A. LeFevre, Cleveland.
Indications for Gastrectomy, Claude J. Hunt, Kansas City, Mo.

After the luncheon address by Mr. Philip G. Green, Washington, D. C., director, Division of Juvenile Delinquency Service, Department of Health, Education, and Welfare, the Ernest E. Shaw Lecture, "Diagnosis and Treatment of Thyroid Disease," will be delivered by Dr. George Crile Jr., Cleveland.

MASSACHUSETTS

Endocrine Society Medal.—The 1956 medal of the Endocrine Society has been bestowed on Frederick L. Hisaw, LL.D., Ph.D., professor of zoology at Harvard University, who discovered relaxin. He also investigated the fundamental nature of the hormonal interrelationships between the pituitary body and the ovary in the regulation of cyclic reproductive functions.

Wien Cancer Award.—Ruth Graham, cytologist from the Massachusetts General Hospital in Boston, has received the Wien award of $1,000 for 1955, in recognition of "outstanding research in cancer cytology." The presentation of the award was made by Dr. Edmund V. Cowdry, St. Louis, at the Cancer Institute at Miami, Fla., following her paper, "Cytologic Evaluation of Radiation Sensitivity of Cancer of the Cervix."

MICHIGAN

Personal.—At commencement exercises June 14, Wayne University, Detroit, bestowed the honorary degree of doctor of laws on Dr. Lawrence Reynolds, professor of radiology. Dr. Reynolds is president of the Detroit Public Library Commission and editor of the *American Journal of Roentgenology, Radium Therapy, and Nuclear Medicine.*

Personal.—Dr. Leo G. Christian, Lansing, a member of the Ingham County Medical Society for 34 years, received the society's Service Citation at its Clinic Day, May 3, in Lansing. The citation read, in part: "Doctor Christian has enriched the practice of medicine in this community, and focused our attention on the significance of medical education in general hospitals."

Psychiatric Hospital Dedicated.—The Lafayette Clinic, a 145-bed psychiatric hospital, adjacent to Wayne University College of Medicine, Detroit, was dedicated May 7. The professional staff, headed by Dr. Jacques S. Gottlieb, is being integrated academically with the university department of psychiatry. The clinic will serve as a research and training hospital in the behavioral sciences. Presently it plans to concentrate its research efforts in three major fields: (1) schizophrenia; (2) factors responsible for defective functioning in children, such as mental deficiency, epilepsy, and cerebral palsy; and (3) study of the primary process of treatment by the psychiatrist—psychotherapy. Diagnostic services of the clinic will be available on a referral basis to the private patients of members of the medical profession. Both outpatients and bedpatients will be accepted, provided they are suitable for the purposes of the clinic.

MONTANA

Society News.—Officers of the Montana chapter of the American Academy of General Practice include Dr. George E. Trobough, Anaconda, president; Dr. William E. Harris, Livingston, president-elect; and Dr. Amos R. Little, Helena, vice-president.

State Medical Meeting in Great Falls.—The 78th annual meeting of the Montana Medical Association (George W. Setzer, Malta, president) and the seventh annual meeting of the Great Falls Medical-Surgical Conference will be held jointly at the Hotel Rainbow in Great Falls, Sept. 13-15. Out-of-state speakers and their first presentations will include:

Frederic C. Bost, clinical professor of orthopedic surgery, University of California School of Medicine, Berkeley-San Francisco, Orthopedic Emergencies of Childhood and Adolescence.
E. Stanley Crawford, assistant professor of surgery, Baylor University College of Medicine, Houston, Texas, Recent Developments in the Management of Occlusive Arterial Disease of the Lower Extremities.
Stanton A. Friedberg, clinical associate professor of otolaryngology, University of Illinois College of Medicine, Chicago, Diseases of the Mouth and Throat (Kodachrome).
Eleanor M. Humphreys, professor of pathology, University of Chicago School of Medicine, Malignant or Benign Disease? Problems in the Right Lower Quadrant.
Arthur J. Jampolsky, assistant clinical professor of surgery (ophthalmology), Stanford University School of Medicine, Stanford University—San Francisco.
Charles E. McLennan, professor of obstetrics and gynecology, Stanford University School of Medicine, Stanford University—San Francisco, Management of Dysfunctional Uterine Bleeding.
Max Miller, associate professor of medicine, Western Reserve University School of Medicine, Cleveland, Historical Developments, Physiological Knowledge and Possible Mechanisms of Action of Orally Administered Sulfonyl-Urea Drugs in Diabetes.
Burtrum C. Schiele, professor of psychiatry, University of Minnesota Medical School, Minneapolis, New Drugs in the Treatment of the Nervous Patient.

The scientific program will include several clinicopathological conferences and a symposium of geriatrics. On Thursday evening the association will hold its annual reception and banquet. The officers of Malmstrom Air Force Base and the Great Falls Chamber of Commerce have arranged a conducted tour of the base for Friday afternoon. On Friday evening the Cascade County Medi-

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

cal Society will be host to Montana physicians and their guests at a dinner dance at the Meadowlark Country Club in Great Falls. All Montana physicians as well as all physicians in the Rocky Mountain area and in Canada are cordially invited to attend this meeting. The women's auxillary will meet concurrently.

NEW YORK

Day Psychiatric Center.—The first of two day hospital centers to be organized by the New York State Department of Mental Hygiene was opened at Hudson River State Hospital, Poughkeepsie, July 2. According to Dr. Paul H. Hoch, state commissioner of mental hygiene, to determine the value of psychiatric and supportive therapy for suitable mental patients in a hospital setting during the daytime hours, patients at the new center will receive psychiatric care on a voluntary outpatient basis, during the day, remaining for the rest of the time at their homes or continuing insofar as possible with their family and community activities. The second day hospital is expected to open in the near future in connection with the Brooklyn Aftercare Clinic, 105 Schermerhorn St. The day hospital has been designed for the care of adults 18 years or older and will operate on a five days a week schedule from 8:30 a. m. to 4 p. m. Patients will be referred primarily by community physicians and social agencies and on a volunteer basis. They also may be accepted after provisional release from the state hospital to complete the course of treatment or for social and vocational readaptation as a means of helping to "tide them over" in making an adjustment from the hospital to the community. The staff of 14 who will administer the day hospital includes Dr. O. Arnold Kilpatrick, director of the Hudson River State Hospital, Dr. Marian F. Axel, psychiatrist-in-charge of the center; two nurses, a social worker; occupational therapist, recreational worker; two male and four female psychiatric aides; and a secretary-receptionist.

New York City

Hospital News.—Lenox Hill Hospital, 111 E. 76th St., has established an Adult Allergy Clinic within the department of medicine, with Dr. Laurence Farmer as attending physician and chief.

Professor of Obstetrics and Gynecology Appointed.—Dr. Martin L. Stone, a member of the faculty of New York Medical College, Flower and Fifth Avenue Hospitals, since 1949, has been appointed professor of obstetrics and gynecology and director of the department. Dr. Stone is a member of the special committee on infant mortality of the New York County Medical Society.

English Course for Foreign Physicians.—A new course in practical English, to be offered during the 1956 autumn semester at New York University's division of general education, will be open to doctors, interns, and hospital administrators whose native tongue is not English. Emphasis will be given to oral and written practice of the vocabulary commonly used in medical histories, consultations, evaluations, case reports, progress notes, and interviews of patients. Several American physicians will serve as guest lecturers for the course. The course, conducted by Mr. Grant Taylor, director of the division's English language program for international students, will be presented from 6:15 to 8 p. m. on Thursdays, Sept. 27-Jan. 17. Interested persons may register either by person or through the mail until October at the Division of General Education, New York University, 1 Washington Sq. North, New York 3.

OREGON

Practitioners Meet in Portland.—The annual meeting of the Oregon chapter, American Academy of General Practice, will convene Sept. 13-15 at the Masonic Temple in Portland under the presidency of Dr. Raymond M. Reichle, Portland. Mr. Mac F. Cahal, executive secretary, American Academy of General Practice, will speak at the banquet at the Heathman Hotel Friday night on "Let the People Behold You." Other out-of-state speakers will include:

H. Corwin Hinshaw, San Francisco, The Questionable Survey Chest X-Ray.
John W. Huffman, Chicago, The Way is Uncharted.
Aram Glorig Jr., Los Angeles, Hearing Loss and the General Physician.
Carl T. Javert, New York, Psychosomatic Abortion.

PENNSYLVANIA

Memorial Tablet. —As the first of a series of events scheduled in connection with the "Year of Commemoration" in Mifflin County, a tablet was unveiled in McVeytown, the birthplace of the late Dr. Joseph T. Rothrock, known as the father of Pennsylvania forestry. Dr. Rothrock, who died in June, 1922, was credited with originating the idea of establishing a tuberculosis hospital at Mont Alto, which resulted in the building of Pennsylvania State Sanatorium No. 1. He served as superintendent of the state sanatorium for consumptives, South Mountain Camp, as professor of botany at the University of Pennsylvania, and as commissioner of forestry. During the commemorative ceremonies, pupils of the Rothrock Joint High School and the Lewistown High School planted thousands of seedlings in memory of Dr. Rothrock.

Philadelphia

Appoint Musser Professor.—Dr. Colin M. MacLeod has been named John Herr Musser Professor of Research Medicine and chairman of the department of research medicine, University of Pennsylvania School of Medicine, to succeed Dr. William C. Stadie, whose retirement with the rank of professor emeritus became effective June 30. Dr. MacLeod has been chairman, department of microbiology, New York University College of Medicine, since 1941. During February and March of this year, he was a member of a mission sent under the auspices of the U. S. Public Health Service to Russia to study research and teaching programs in medical education. Dr. MacLeod, whose special fields of interest are infectious diseases, microbial genetics, and immunology, is a member of the Armed Forces Epidemiological Board, a member of the advisory panel on medical sciences to the Assistant Secretary of Defense for Research and Development, and a consultant to the surgeon general of the Army. Since 1945 he has been associate editor of the *Journal of Immunology*.

Personal.—Earle H. Spaulding, Ph.D., head, department of microbiology, Temple University Medical Center, has been appointed chairman of the advisory committee of certification of the newly organized American Academy of Microbiology.——Dr. Louis H. Clerf, emeritus professor of bronchoesophagology and laryngology, Jefferson Medical College of Philadelphia, has received the 33rd annual Strittmatter award of the Philadelphia County Medical Society, of which he is a past-president.——At the annual meeting of the Endocrine Society, June 7-9 in Chicago, the Ciba award for outstanding research in human endocrine glands, particularly as they affect the development of the child, was presented to Dr. Alfred M. Bongiovanni, associate professor of pediatrics at the University of Pennsylvania School of Medicine. Dr. Bongiovanni, who is currently secretary of the Philadelphia Endocrine Society, received the award for work on the chemical nature of adrenal cortex hormones.——Mr. Edward R. Loveland, for more than 30 years executive secretary of the American College of Physicians, has been made an honorary fellow of the college—the only layman ever so honored. He was presented with an illuminated certificate, reading in part: "As executive secretary of the college from 1926-1956 his ability and devotion have been outstanding. His services have been distinguished by his constant adherence to the highest traditions of the medical profession."

Pittsburgh

Society News.—The Pittsburgh Roentgen Society recently elected Dr. Newton Hornick, Pittsburgh, president; Dr. J. Dutney Hayes, Mt. Lebanon, Pa., vice-president; Dr. Norman B. Tannehill, Pittsburgh, secretary; and Dr. Harrison H. Richardson, Rochester, Pa., treasurer.

RHODE ISLAND

Dr. Donley to Edit State Journal.—Dr. John E. Donley, past-president of the Rhode Island Medical Society, the Providence Medical Association, and the Rhode Island Society of Psychiatry and Neurology, has been named editor-in-chief of the *Rhode Island Medical Journal*, succeeding the late Dr. Peter Pineo Chase. John E. Farrell, Sc.D., continues as managing editor. Dr. Donley was the recipient of the City of Providence Charles V. Chapin medal award in 1955 and in 1953 received a citation from President Eisenhower's Committee on Employment of the Physically Handicapped for his "outstanding services to the disabled" in Rhode Island. Medical director of the Rhode Island Curative Center, Dr. Donley has been chairman of the publications committee of the state medical society for more than 10 years.

TENNESSEE

Refresher Course for Nurses.—In an attempt to overcome a shortage of registered nurses that has hampered the opening of additional floors in the new E. H. Crump Memorial Hospital, the University of Tennessee School of Nursing and the city of Memphis will offer a refresher course, Sept. 10-Oct. 5 at the John Gaston Hospital, for registered nurses now inactive who wish to return to the profession. The fee of $40 will be refunded to those nurses who complete the course and are employed in a permanent position by Memphis city hospitals.

WASHINGTON

State Medical Meeting in Seattle.—The 67th annual session of the Washington State Medical Association will convene in the Olympic Hotel, Seattle, Sept. 16-19. Dr. Dwight H. Murray, Napa, Calif., President of the American Medical Association, will be at the general assembly, Tuesday, 11 a. m., with Dr. L. C. Munger Jr., Vancouver, Canada, who will deliver his presidential address. The complimentary public relations luncheon on Wednesday will have as its theme "Congress, Doctors, and Politics." Panel members discussing the subject will be Dr. J. Lafe Ludwig, Los Angeles, member of the A. M. A. Committee on Legislation; C. Joseph Stetler, Chicago, LL.M., Director of the A. M. A. Law Department; and Richard G. Van Buskirk, LL.B., Chicago, Executive Secretary, A. M. A. Committee on Legislation. A panel has been scheduled on pitfalls in ocular diagnosis and a symposium on asyphxia in the newborn. Two symposiums will also be presented at the eye, ear, nose, and throat section. The following presentations will be made by out-of-state speakers:

Treatment of Psychiatric Problems by Family Physicians, Alexander Simon, San Francisco.
Malpractice Hazards of Drug Therapy, Harry Gold, New York.
Misuse of Endocrine Preparations, Carl G. Heller, Portland, Ore.
Nonobstetrical Problems Associated with Pregnancy, William J. Dieckmann, Chicago.
Problems and Importance of Biopsies and Exfoliative Cytology, James W. Reagan, Cleveland.

Social events will include the annual banquet and dance Tuesday evening (dress optional), the informal no-host family dinner Sunday evening, and a reception Wednesday evening. Headquarters for the annual fishing derby Monday will be Ray's Boathouse, Ballard. The golf tournament will be on Monday at the Seattle Golf and Country Club. The Sportsmen's Banquet is scheduled for Monday evening in the clubhouse of the latter club. The woman's auxiliary will meet concurrently.

WEST VIRGINIA

Symposium on Endocrinology.—A symposium on endocrinology, sponsored by the Cabell County Medical Society, will be held at the Pritchard Hotel in Huntington, Sept. 13. Physicians are cordially invited to this open meeting. Dr. Charles H. Read, associate professor of pediatrics, State University of Iowa College of Medicine, Iowa City, the sole speaker at the morning session, will discuss "Endocrine Problems of Infancy." The following program will be presented during the afternoon sessions:

Endocrine Problems of the Adolescent, Anne P. Forbes, instructor in medicine, Harvard Medical School, Boston.
The Thyroid Gland, William W. Engstrom, associate professor of medicine, Marquette University School of Medicine, Milwaukee.
Current Aspects of Adrenal Disease, Emile E. Werk Jr., associate professor of clinical medicine, University of Cincinnati School of Medicine, Cincinnati.

A cocktail party, 6 p. m., will precede dinner, 7 p. m., at which Dr. Thomas G. Folsom, Huntington, will serve as toastmaster. A panel discussion with questions and answers will follow the dinner.

Meeting on Tuberculosis.—The 36th annual meeting of the West Virginia Tuberculosis and Health Association will be held at the New Beckley Hotel in Beckley, Sept. 13-14, in cooperation with the Raleigh County Tuberculosis and Health Association. The president, Dr. Harold H. Howell of Madison, will preside at the annual business luncheon Thursday, 12 noon, and Dr. John W. Whitlock of Beckley, president of the Raleigh County Medical Society, at the afternoon scientific session arranged by the West Virginia Trudeau Society. Dr. Harry E. Walkup, chief of surgery at the Veterans Administration Hospital, Oteen, N. C., will present a paper on "Asymptomatic Pulmonary Lesion and Unresolved Pneumonia," and Dr. Howard M. Payne, professor of medicine, Howard University College of Medicine, Washington, D. C., will discuss "Basic Considerations in the Problem of Tuberculosis." The final paper (subject to be announced) will be presented by Dr. Sol Katz of Washington, D. C., chief, division of pulmonary diseases, District of Columbia General Hospital. Members of the board of directors of the Raleigh County Tuberculosis and Health Association will be hosts at a reception, 6 p. m., preceding the annual banquet, at which the guest speaker will be Mr. L. Steele Trotter, treasurer, West Virginia Board of Control, who will discuss "Problems Relating to West Virginia Sanatoria." At the general session Friday morning, Mr. Ray Milliron, president, Raleigh County Tuberculosis and Health Association, will preside. "The Role of the Department of Public Assistance in Providing Services to the Disabled" will be presented by Mr. Earle Wolfe, chief, division of social services, West Virginia State Department of Public Assistance, Charleston, and "The Public Health Nurse in Tuberculosis Control" by Miss Sheila Dwyer, assistant director of nursing service, Harlan Memorial Hospital, Miners Memorial Hospital Association, Harlan, Ky. Dr. Joseph E. Martin Jr. of the department of internal medicine, the Golden Clinic, Elkins, will be the final speaker on the program (subject to be announced).

WISCONSIN

University News.—Dr. Albert C. Schmidt, chief of surgery at Milwaukee Children's Hospital and chief of orthopedics at Columbia Hospital, Milwaukee, has been named clinical professor of orthopedic surgery at Marquette University School of Medicine, where from 1946 to 1952 he was assistant clinical professor.

Grant in Human Genetics.—The University of Wisconsin Medical School, Madison, will begin a new program of study in human genetics next fall through a three-year grant of $25,000 from the Rockefeller Foundation. Dr. Newton Morton, a recent graduate of the department of genetics at Wisconsin, will direct the study, teach a course in human genetics, the first of its kind offered in the medical school, and give lectures emphasizing genetics in other aspects of medical, surgical, and pediatrics practices. During 1952-1953 Dr. Morton was a member of the Atomic Bomb Casualty Commission of Hiroshima, Japan, which studied the effects of the atomic radiations on the citizens of Hiroshima.

GENERAL

Federal Hospital Alumni Breakfast.—During the American Hospital Association convention, the Federal Hospital Institute Alumni Association will hold its annual breakfast meeting at the Palmer House, Chicago, Sept. 18, 8 a. m. Captain Edward S. Lowe, commanding officer, U. S. Naval Hospital, Great Lakes, Ill., is in charge of arrangements. Cost of the breakfast is $3.25 per alumnus.

Research in Blood Diseases.—The Hematology Research Foundation invites applications for grants-in-aid in hematological research for a period of one year. Nine copies of application (forms available on request) must be submitted no later than Oct. 15 to the Hematology Research Foundation, 64 W. Randolph St., Chicago 1. Awards will be announced by the medical advisory board of the foundation the first part of November. The board will choose the applicants on the basis of merit of the proposed research project.

Chemists Meet in Atlantic City.—The 130th national meeting of the American Chemical Society will convene at Atlantic City, N. J., Sept. 16-21. Symposiums will be held on methods of combating air pollution, research on promising new drugs, improvements in science education, new findings in the field of cosmetics, use of radioactive materials to sterilize foods and medicines, carbohydrate metabolism and diabetes, and recent advances in cancer research. Mr. Robert C. Watson, United States commissioner of patents, will speak on "Patents and Pharmaceuticals" at a luncheon of the division of medicinal chemistry on Wednesday.

Essay Contest for Welfare Workers.—The recently established Foundation for Voluntary Welfare (214 Front St., San Francisco), a nonprofit corporation, announces its National Awards Com-

GOVERNMENT SERVICES

AIR FORCE

New Air Force Hospital.—The newest of the United States Air Force's medical treatment facilities, a 50-bed hospital, was dedicated at Kindley Air Force Base in Bermuda on June 21, 1956. This is a permanently constructed two-story concrete structure, incorporating many of the newest developments in hospital planning. The principal guest speakers at the dedication ceremony were Dr. Frank B. Berry, Assistant Secretary of Defense (Health and Medical); Lieut. Gen. Sir John Woodall, governor of Bermuda; and Major Gen. William H. Powell, deputy surgeon general of the U.S. Air Force. Also attending the ceremony were Rear Adm. B. E. Bradley, deputy surgeon general of the U.S. Navy; Dr. Wilburt C. Davison, dean of the Duke University Medical School; Col George W. Peterson, commander of Kindley Air Force Base, Major Ignatius Stein, commander of the hospital; many local dignitaries, and members of the Air Force surgeon general's staff and the Military Air Transport Service surgeon's staff.

Personal.—Brig. Gen. Harold H. Twitchell will be the key speaker at the semiannual meeting of the Fairfield County Medical Association of Connecticut on Oct 3 The subject will be "The Utilization of Reserve Medical Personnel During Total War."

ARMY

Curator of Museum Retires.—Col Hugh R Gilmore Jr, M C., curator of the Medical Museum of the Armed Forces Institute of Pathology, has retired from the Army. After several years in private practice, Colonel Gilmore joined the Army Medical Corps in 1926. In World War II, he was preventive medicine officer for various command headquarters in the North African and Italian Theater of Operations. He has been awarded the on of Merit, the Bronze Star, the European Theater of Op- ons campaign ribbon with four stars, the Italian Order of Crown, and the Italian Cross of Military Valor He is a mate of the American Board of Pathology.

New Commandant at Army Institute of Research.—Col Richard P Mason, M. C., U. S. Army, has been named commandant of Walter Reed Army Institute of Research in Washington, D C. He succeeds Brig. Gen John R. Wood, M C, who has retired from the Army to accept the position of vice-president and director of research of a New York pharmaceutical company.

NAVY

Admiral Pugh Retired.—Rear Adm Lamont Pugh retired on Aug. 1. In June, 1917, shortly after the United States entered World War I, he enlisted in the U S. Marine Corps, serving as a private and later as a corporal At the war's end he was in the Officers' Training School, Quantico, Va. He returned to civil life in 1919 and won the Herndon Scholarship in the department of medicine at the University of Virginia In compliance with a requirement of the scholarship, he entered the Medical Corps of the Navy on receiving his degree of doctor of medicine in 1923 In December, 1946, he was made deputy and assistant chief of the Bureau of Medicine and Surgery, Navy Department, with the rank of rear admiral, and in December, 1950, he was named surgeon general of the Navy and chief of the Bureau of Medicine and Surgery, an office that he held for four years. After the expiration of his four-year tenure he became the inspector general for the medical department of the Navy and remained in that office until ordered to command the National Naval Medical Center, Bethesda, Md., in September 1955.

Research Unit Established in Formosa.—Ceremonies inaugurating the establishment of the U. S. Naval Medical Research Unit no. 2, at Taipei, Taiwan (Formosa), were held on June 22 and included addresses by Carl L. Rankin, U. S. ambassador to China, and Chien Szu Leing, president of the National Taiwan University. The commanding officer of the unit is Capt. Robert A. Phillips, M. C., U. S. Navy.

Personal.—Capt. Frank P. Gilmore, M. C, U. S. Navy, has been raised to the grade of rear admiral Since April, 1955, he has been commanding officer of the U. S. Naval Hospital, Chelsea, Mass

PUBLIC HEALTH SERVICE

Examinations for Medical Officers.—A competitive examination for appointment of medical officers to the regular corps of the U. S. Public Health Service will be held in various places throughout the country on Nov. 27, 28, 29, and 30, 1956 Appointments provide opportunities for careers in clinical medicine, research, and public health. They will be made in the ranks of assistant and senior assistant, equivalent to Navy ranks of lieutenant (j g) and lieutenant. Entrance pay for both grades for persons with dependents is $7,498 per year (Assistant grade entrants are assigned the temporary grade of senior assistant.) Qualified officers are promoted at regular intervals Benefits other than promotions include periodic pay increases, 30 days of annual leave, sick leave, medical care, disability retirement pay, regular retirement pay (three-fourths of annual basic pay at time of retirement), and other priviledges. Active duty as a Public Health Service officer fulfills the obligation of Selective Service Requirements for both ranks are U S citizenship, age of at least 21 years, and graduation from a recognized school of medicine For the rank of assistant surgeon, at least seven years of collegiate and professional training and appropriate experience are needed For senior assistant surgeon, an additional three years, or a total of at least 10 years of collegiate and professional training and appropriate experience, are required. Entrance examinations will include an interview, physical examination, and comprehensive objective examinations in the professional field. Application forms may be obtained from the Chief, Division of Personnel, Public Health Service. Department of Health, Education, and Welfare, Washington 25, D.C. Completed application forms must be received in the division of personnel no later than Oct. 13, 1956

National Library of Medicine.—President Eisenhower has signed a bill establishing a National Library of Medicine in the Public Health Service and transferring to it all of the functions of the Armed Forces Medical Library. In carrying out the provisions of the National Library of Medicine Act. the surgeon general will be guided by the advice and recommendations of a Board of Regents. The board will consist of seven ex officio members—the surgeons general of the Public Health Service, Army, Navy, and Air Force, the chief medical director of the department of medicine and surgery of the Veterans Administration, the assistant director for biological and medical sciences of the National Science Foundation, the Librarian of Congress, and 10 additional members appointed by the President with the consent of the Senate. The appointive members will serve four years The exact site of the library has not been determined but will be selected by the surgeon general after consultation with the Board of Regents

Training Grants.—The Public Health Service's National Institute of Neurological Diseases and Blindness will make funds available to medical schools to strengthen existing clinical programs in advanced training in the neurological diseases in order to stimulate the interest of more young physicians and scientists in careers as teachers and investigators Training grants also are available to basic science departments to expand postdoctoral training programs in the neurological sciences. Further information, together with application forms, may be obtained from the Chief, Extramural Programs, National Institute of Neurological Diseases and Blindness, National Institutes of Health, Bethesda 14, Md.

New Surgeon General.—Dr. Leroy E. Burney was sworn in on Aug. 8 for a four-year term as surgeon general of the Public Health Service, succeeding Dr. Leonard Scheele, who resigned Aug. 1. Dr. Burney is the eighth person to hold the office of surgeon general. His entire professional career has been spent in public health activities. At the time of his appointment as surgeon general, he was assistant surgeon general and deputy chief of the Bureau of State Services in the Public Health Service

DEATHS

Zahn, Daniel W. ⊕ Seattle; born in New York May 2, 1911; University of Glasgow Medical Faculty, Glasgow, Scotland, 1938; clinical assistant professor of medicine at University of Washington School of Medicine; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Trudeau Society; president of the Western Tuberculosis Conference and the Pacific Northwest Trudeau Society; veteran of World War II; interned at the Bellevue Hospital in New York City, where he served a residency; medical director of Firland Sanatorium; died in the Swedish Hospital May 6, aged 45, of cerebral thrombosis.

Noble, Willis Clarke, Jr., New York City; born in Peking, China, May 19, 1885; University and Bellevue Hospital Medical College, New York City, 1925; served on the faculty of his alma mater; formerly bacteriologist in charge of the division of laboratories and research of the New York State Department of Health, and assistant director of the research laboratory of the New York City Health Department; for many years supervisor of the biochemical laboratory of the Metropolitan Life Insurance Company; member of the Society of Bacteriologists, Association of Immunologists, and the Harvey Society; died in St. Clare's Hospital May 24, aged 71.

Mitchell, Myron Skupnik, Brooklyn, N. Y.; born in 1890; Universität Bern Medizinische Fakultät, Bern, Switzerland, 1916; member of the Medical Society of the State of New York and the American Academy of Dermatology and Syphilology, American Public Health Association, and the Brooklyn Academy of Medicine; medical director of the department of welfare; admitting physician at Kings County and Coney Island hospitals; a lecturer on communicable diseases for the department of health, of which he was a physician, and a physician at the Social Hygiene Clinic; died May 12, aged 66, of coronary disease.

Almes, Emanuel M. ⊕ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1937; interned at the Woman's Homeopathic Hospital; veteran of World War II; member of the Industrial Medical Association; associated with the Olney Hospital and Lawncrest Diagnostic Clinic; died May 24, aged 45, of carcinoma of the lungs.

Barnes, Boisey Otha, Wilson, N. C.; Meharry Medical College, Nashville, Tenn., 1932; interned at St. Agnes Hospital in Raleigh; died in the Mercy Hospital April 24, aged 53, of carcinoma of the lung.

Barnum, Francis Goodell ⊕ Brookline, Mass.; Harvard Medical School, Boston, 1907; Boston school committee physician for 40 years and a past-president of the Society of Examining Physicians; veteran of World War I; died May 30, aged 78.

Bell, George Erick ⊕ Wilson, N. C.; Jefferson Medical College of Philadelphia, 1921; fellow of the American College of Physicians; veteran of World War I; past-president of the Wilson County Medical Society; member of the county board of health; president of the Woodard-Herring Hospital; member of the board of trustees of the Eastern North Carolina Sanatorium and the Wake Forest (N. C.) Sanatorium; a director in the National Bank; died in Morehead City May 26, aged 63, of a heart attack.

Blakeman, Lloyd James ⊕ Antioch, Ill.; Chicago College of Medicine and Surgery, 1917; veteran of World War I; on the staffs of the Chicago Memorial and Columbus hospitals in Chicago; died in the Michael Reese Hospital, Chicago, July 7, aged 64, of carcinoma of the bladder.

Blaney, Lilton D., Richmond, Va.; Leonard Medical School, Raleigh, 1911; died March 1, aged 81, of pernicious anemia.

Bigelow, Alice Houghton, Boston; Tufts College Medical School, Boston, 1905; member of the Massachusetts Medical Society; served on the staff of the New England Hospital, where she died May 10, aged 81, of uremia, pyelonephritis, and pappillary carcinoma of the bladder.

Brace, William Morgan ⊕ Ann Arbor, Mich.; University of Michigan Medical School, Ann Arbor, 1923; past-president of the Washtenaw County Medical Society; fellow of the American College of Physicians; veteran of World War I; assistant professor, University of Michigan School of Public Health; physician, health service, University of Michigan; died in the University of Michigan Hospital April 23, aged 61, of fibrosis of the lungs and cor pulmonale.

Bullock, Duncan Douglas ⊕ Rowland, N. C.; Medical College of South Carolina, Charleston, 1920; served during World War II; died in the Charlotte (N. C.) Memorial Hospital April 29, aged 62, of acute myocardial infarction.

Burley, Benjamin Thomas ⊕ Cohasset, Mass.; Harvard Medical School, Boston, 1901; specialist certified by the American Board of Psychiatry and Neurology; member of the Association for Research in Nervous and Mental Diseases; formerly practiced in Worcester, where he was consulting neurologist at the Belmont, Fairlawn, and Worcester City hospitals; consulting neurologist at the Harrington Memorial Hospital in Southbridge, Holden (Mass.) District Hospital, and Webster (Mass.) District Hospital; died in Worcester May 16, aged 81, of arteriosclerosis.

Carter, Charles W., Tacoma, Wash.; University of Oregon Medical School, Portland, 1916; died May 13, aged 74, of cardiac decompensation, and generalized arteriosclerosis.

Cifaldi, Alexis, Staten Island, N. Y.; Long Island College Hospital, Brooklyn, 1904; served on the staff of the Parkway Hospital in New York City, where he died May 29, aged 76, of cerebral hemorrhage.

Coburn, Clay Ephraim ⊕ Kansas City, Kan.; Hahnemann Medical College of the Kansas City University, Kansas City, Mo., 1899; Kansas City (Mo.) Hahnemann Medical College, 1906; for 23 years a member of the Kansas State Board of Health, serving two terms as its president; for many years a member of the Kansas Tuberculosis and Health Association, which he served as president; veteran of World War I; died June 8, aged 83, of coronary occlusion.

Clanton, Albert Williamson ⊕ Millport, Ala.; Mississippi Medical College, Meridian, 1907; died in the Lamar County General Hospital in Vernon May 21, aged 76.

Cope, Roscoe Ziegler, Hatfield, Pa.; Jefferson Medical College of Philadelphia, 1913; on the staff of the Grand View Hospital in Sellersville; died June 7, aged 68, of congenital heart disease.

Courtney, Robert Hull ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1919; professor of clinical ophthalmology at his alma mater; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society, and the Association for Research in Ophthalmology; on the staff of the Hospital Division of the Medical College of Virginia, where he died May 23, aged 63, of acute circulatory collapse following fracture of the hip incurred in a fall.

Cox, Jane McMahan ⊕ Lewiston, Idaho; Temple University School of Medicine, Philadelphia, 1945; interned at the Philadelphia General Hospital, where she served a residency; on the staff of St. Joseph's Hospital; died June 1, aged 48, of coronary disease.

Crone, Virgil Duane ⊕ Beloit, Wis.; St. Louis College of Physicians and Surgeons, 1906; member and past-president of the staff at the Beloit Municipal Hospital; died June 3, aged 83, of bleeding duodenal ulcer.

Custis, Marvin A. ⊕ Washington, D. C.; Hahnemann Medical College and Hospital of Philadelphia, 1890; president from 1935 to 1947, when he became chairman of the board of the Perpetual

---

⊕ Indicates Member of the American Medical Association.

Building Association, which he had joined in 1914 as director and trustee, and later became treasurer; formerly vice-president of the Fidelity Investment Company, serving as president from 1930 to 1945; died in Gloucester, Mass., June 3, aged 89.

Davis, John Allison, Brooklyn, N. Y.; Long Island College of Medicine, Brooklyn, 1938; interned at the Wyckoff Heights Hospital; served a residency at the Carson C. Peck Memorial Hospital and St. John's Episcopal Hospital, where he died June 11, aged 48, of bronchogenic carcinoma with metastases to the brain.

Davis, Robert Allen ✠ Newport News, Va.; University of Virginia Department of Medicine, Charlottesville, 1909; member of the Radiological Society of North America; past-president of the Seaboard Medical Association and the Warwick County Medical Society; veteran of World War I; on the staffs of the Dixie Hospital in Hampton and the Riverside and Mary Immaculate hospitals; died April 29, aged 69, of coronary thrombosis.

Deer, Blan Forsythe ✠ Lake Worth, Fla., University of Louisville (Ky.) Medical Department, 1914; member of the Indiana State Medical Association; for many years practiced in Indianapolis; died May 8, aged 68, of paralysis agitans.

Dinnison, James Andrew, Ashtabula, Ohio, Jefferson Medical College of Philadelphia, 1912; an associate member of the American Medical Association; member of the Medical Society of the State of Pennsylvania; died in the Ashtabula General Hospital April 14, aged 78, of coronary occlusion.

Doan, Edward B., Miamisburg, Ohio; Cleveland Homeopathic Medical College, 1899; for many years served on the county board of health, an honorary member of the staff of the Miami Valley Hospital in Dayton; charter member of the Miamisburg Rotary Club, formerly director of the First National Bank; died May 17, aged 87, of cancer.

Duffy, Vincent Paul ✠ Grafton, W. Va., University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1917, member of the Connecticut State Medical Society; died May 3, aged 72, of cerebral hemorrhage.

Dunham, Harry Bartlett, Glendora, Calif.; Dartmouth Medical School, Hanover, N. H., 1912; died in San Bernardino June 3, aged 70.

Ewing, Edward W., Spickard, Mo.; Rush Medical College, Chicago, 1899; died May 29, aged 80.

Feitler, Alfred George, Elmhurst, N. Y.; Medizinische Fakultät der Universität, Vienna, Austria, 1905; member of the Medical Society of the State of New York; died June 6, aged 75, of carcinoma of the liver.

Ferraro, Francis Peter ✠ Pittsburgh; University of Pittsburgh School of Medicine, 1937; fellow of the International College of Surgeons and the American College of Surgeons; on the staff of St. Francis Hospital, where he died June 2, aged 43, of coronary disease.

Fink, Frank Carl, Pleasant Plains, Ill.; Washington University School of Medicine, St. Louis, 1904; died May 29, aged 75, of heart disease.

Fishman, Samuel ✠ Washington, D. C.; University of Buffalo School of Medicine, 1933; veteran of World War II; on the staffs of the Doctors and Garfield Memorial hospitals; died in Silver Spring, Md., May 30, aged 47, of coronary occlusion.

Frohwein, Ida Louise E. Haverstick, Elizabeth, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1901; an associate member of the American Medical Association; for many years chief physician in charge of the city's child hygiene department; died in Cranford May 27, aged 77, of cerebral thrombosis.

Garrett, Nevil McClure, Brodhead, Ky.; Louisville (Ky.) Medical College, 1897; past-president of the Rockcastle County Medical Society; member of the Kentucky State Medical Association; died March 2, aged 85, of heart disease.

Gelhaus, William John ✠ Monroe, Mich.; Ohio State University College of Medicine, Columbus, 1923; died May 30, aged 59, of coronary thrombosis.

George, William Adolph ✠ Selby, S. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; served on the staff of the Mobridge (S. D.) Hospital; died May 22, aged 82, of an injury incurred in a fall from his bed.

Gibans, Myer Jacob ✠ Akron, Ohio; Western Pennsylvania Medical College, Pittsburgh, 1905; member of the American Academy of Dermatology and Syphilology; formerly on the consulting staff of the Barberton (Ohio) Citizens Hospital and the Akron City Hospital; died in the Akron General Hospital May 18, aged 73, of gingival carcinoma with metastases.

Goldcamp, Edward C., Youngstown, Ohio; Jefferson Medical College, Philadelphia, 1914; specialist certified by the American Board of Otolaryngology; formerly vice-president of the Mahoning County Medical Society; served in France during World War I; on the staff of the Youngstown Hospital; died June 2, aged 65, of carcinoma of the stomach and colon.

Grady, Grover Quinton ✠ Highland Park, Ill.; Rush Medical College, Chicago, 1919; fellow of the American College of Surgeons; past-president of the Lake County Medical Society; on the staff of the Lake Forest (Ill.) Hospital and the Highland Park Hospital; died in Eagle River, Wis., June 23, aged 63.

Hearne, Charles Alfred ✠ Corpus Christi, Texas; Denver and Gross College of Medicine, Denver, 1904; a director and past-president of the Nueces County Tuberculosis Association; formerly a medical officer for the health department of the Panama Canal Zone; died May 25, aged 80, of heart disease and diabetes mellitus.

Hermann, George Fred, Cincinnati; Eclectic Medical College, Cincinnati, 1916; veteran of World War I; died May 23, aged 62, of coronary thrombosis.

Herrman, Harold C. ✠ New York City; University and Bellevue Hospital Medical College, New York City, 1920; on the staff of the Mount Sinai Hospital; died April 13, aged 59, of muscular dystrophy.

Hill, John Augustus, Allenhurst, N. J.; College of Physicians and Surgeons, medical department of Columbia College, New York City, 1894; died May 27, aged 84.

Hill, Roland ✠ St. Louis; Trinity Medical College, Toronto, Canada, 1890; member of the founders group of the American Board of Surgery; member of the Western Surgical Association, of which he was past-president; fellow of the American College of Surgeons; past-president of the St. Louis Surgical Society and the St. Louis Medical Society; consultant, Evangelical Deaconess Hospital and St. Luke's Hospital; died May 27, aged 87.

Hodgkin, Williard Edward ✠ Spokane, Wash.; College of Medical Evangelists, Loma Linda and Los Angeles, 1934; interned at the Portland (Ore.) Sanitarium and Hospital; died in St. Luke's Hospital June 4, aged 47, of coronary disease.

Hodsdon, Benjamin Franklin, Jacksonville, Fla.; Medical School of Maine, Portland, 1897; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; an associate member of the American Medical Association; member of the American Academy of Ophthalmology and Otolaryngology; past-president of the Dade County Medical Society; served on the staff of the Jackson Memorial Hospital in Miami; died May 29, aged 90, of coronary occlusion.

Horne, Frederick, Carriere, Miss.; University of Tennessee Medical Department, Nashville, Tenn., 1907; died March 2, aged 79, of arteriosclerosis.

Husted, Franklin Pitkin ✠ Bay City, Mich.; University of Michigan Medical School, Ann Arbor, 1929; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; member of the Industrial Medical Association; president-elect of the Bay County Medical Society; served five years in African and European campaigns in World War II; on the staffs of the Bay City and Mercy hospitals; died in St. Francis Hospital, Miami Beach, Fla., May 17, aged 51, of coronary thrombosis.

Jackson, Lindsay A., Fort Myers, Fla.; Cleveland Homeopathic Medical College, 1898; died May 21, aged 80.

Jackson, Nathaniel E., Laurinburg, N. C.; Leonard Medical School, Raleigh, 1907; died May 31, aged 75, of adenocarcinoma of the stomach.

Janci, Julius Sebastian ⊕ Owosso, Mich.; Wayne University College of Medicine, Detroit, 1935; died May 31, aged 51.

Jellison, Robert Thompson ⊕ Salt Lake City; John A. Creighton Medical College, Omaha, 1914; veteran of World War I; served on the medical staff of Kennecott Copper Corporation, Western Division, from 1915 until his retirement; for many years on the staff of St. Mark's Hospital; died May 17, aged 63, of coronary occlusion.

Johnson, James White, Union Level, Va.; Baltimore Medical College, 1907; died May 31, aged 76.

Jones, Edgar A. P. ⊕ Cambridge, Md.; Baltimore Medical College, 1893; formerly deputy state health officer in Dorchester County; served as a member of the state board of health, and in the Maryland legislature; on the staff of the Cambridge-Maryland Hospital; died May 27, aged 83, of arteriosclerosis.

Jones, Edward Hallaran, San Angelo, Texas; Jefferson Medical College of Philadelphia, 1912; died May 28, aged 71, of coronary thrombosis.

Jones, Ulysses Simpson Grant, Norfolk, Va.; Leonard Medical School, Raleigh, N. C., 1913; died in the Norfolk Community Hospital April 6, aged 70, of hypertensive cardiorenal syndrome.

Keisling, Frederick Carter ⊕ Jacksonville, Fla.; St. Louis College of Physicians and Surgeons, 1906; on the staff of the St. Luke's Hospital; died May 18, aged 72, of hypertension.

Keller, Morris David ⊕ New York City; Columbia University College of Physicians and Surgeons, New York City, 1907; died June 9, aged 72, of acute coronary artery thrombosis.

Keyes, Paul Hunt, Lakeland, Fla.; Medical College of Indiana, Indianapolis, 1901; retired in 1953 as a member of the Employees Compensation Board, Department of Labor at Washington, D. C.; died May 18, aged 75, of arteriosclerotic heart disease.

Kraft, Alfred Hartman, Aspinwall, Pa.; University of Pittsburgh School of Medicine, 1913; died March 23, aged 69, of coronary occlusion and arteriosclerosis.

Lininger, Carl Blaine ⊕ Erie, Pa.; Cleveland Homeopathic Medical College, 1911; veteran of World War I; died in the Hamot Hospital May 23, aged 71, of myocardial infarction and arteriosclerosis.

McCracken, Jacob O. ⊕ Montgomery, Ind.; Medical College of Indiana, Indianapolis, 1905; on the staff of the Daviess County Hospital, Washington, where he died May 12, aged 81, of carcinoma of the nasopharynx.

Massover, Alfred Jacob ⊕ Chicago; Rush Medical College, Chicago, 1940; interned at Michael Reese Hospital in Chicago; formerly a resident at the Edward J. Meyer Memorial Hospital in Buffalo; veteran of World War II; on the staffs of the Grant, Alexian Brothers, and Walther Memorial hospitals in Chicago; died June 12, aged 44, of coronary thrombosis.

Mehl, Rudolph Alfred ⊕ Evansville, Ind.; Emory University School of Medicine, Atlanta, 1931; on the staffs of the Protestant Deaconess and St. Mary's hospitals; died May 21, aged 50, of coronary occlusion.

Messick, William Rodney, Rehoboth Beach, Del.; Hahnemann Medical College and Hospital of Philadelphia, 1896; retired druggist; served as mayor; on the staff of the Beebe Hospital in Lewes; died in the Delaware Hospital, Wilmington, June 16, aged 83, of cerebral hemorrhage.

Ninde, Frederick Ward, New York City; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; an associate member of the American Medical Association; died in the Harlem Hospital May 21, aged 78, of pneumonia.

Owens, Raymond Leroy ⊕ Livermore, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1925; member of the American Academy of General Practice; past-president of the San Joaquin County Medical Society; veteran of World War I; on the staff of St. Paul's Hospital; died June 4, aged 60, of arteriosclerotic cardiovascular disease.

Robertson, Stanley Barnes ⊕ Detroit; Detroit College of Medicine and Surgery, 1918; on the staff of the Detroit Memorial Hospital; member of the American Academy of General Practice; died June 8, aged 64.

Thomson, George Geddes, Rockaway, N. J.; Long Island College Hospital, Brooklyn, N. Y., 1896; died in St. Clare's Hospital, Denville, June 30, aged 89, of postoperative gas bacillus infection.

Tingdale, August C. ⊕ Minneapolis; Minneapolis College of Physicians and Surgeons, 1902; served as superintendent of the Minneapolis workhouse; on the staff of the Lutheran Deaconess Home and Hospital, where he died June 5, aged 83, of cerebral hemorrhage.

Tomlinson, Hubert George, Duffield, Va.; Medical College of Virginia, Richmond, 1952; interned at the Lewis-Gale Hospital in Roanoke; died in Johnston Memorial Hospital, Abingdon, April 30, aged 32, of astrocytoma.

Tower, Samuel, Brooklyn, N. Y.; General Medical College, Chicago, 1923; died in the Coney Island Hospital June 29, aged 63, of myocardial infarction.

Van Buren, Howard Gunther ⊕ Hines, Ill.; University of Illinois College of Medicine, Chicago, 1950; interned at the West Suburban Hospital in Oak Park; associated with the Veterans Administration Hospital, where he served a residency; died in the Veterans Administration Hospital in Biloxi, Miss., April 6, aged 37.

Vaughan, Edward W. ⊕ Port Arthur, Texas; Chicago College of Medicine and Surgery, 1910; died in Lampasas July 3, aged 76.

Vaughan, Richard Wingfield ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1916; on the staffs of the Grace and Richmond Eye, Ear, Nose and Throat hospitals, and the Retreat for the Sick; died in St. Elizabeth Hospital June 30, aged 63, of a heart attack.

Vesely, F. Vaclav ⊕ Lewellen, Neb.; University of Nebraska College of Medicine, Omaha, 1940; member of the American Academy of General Practice; instantly killed in an automobile accident June 8, aged 41.

Waldinger, Emanuel, Old Saybrook, Conn.; New York Homeopathic Medical College and Hospital, New York City, 1921; fellow of the American Geriatrics Society and the American Association for the Advancement of Science; died June 30, aged 58.

Warren, Thomas Francis ⊕ Fall River, Mass.; Baltimore Medical College, 1905; veteran of the Spanish-American War; died July 5, aged 77.

Wheeler, James Alexander Van Vleck ⊕ Jersey City, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1904; vice-president of the board of directors of Fairmount Hospital; died June 29, aged 75, of carcinoma of the colon.

Wichman, August Gustav, St. Louis; Washington University School of Medicine, St. Louis, 1902; on the staffs of St. Mary's and Evangelical Deaconess hospitals; died in St. Mary's Hospital July 5, aged 76, of carcinoma of the pharynx.

Wilcox, Earl Victor ⊕ Flanagan, Ill.; Chicago College of Medicine and Surgery, 1914; died in St. James Hospital, Pontiac, June 6, aged 80.

Wilkins, John Crawford, Cathedral City, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; veteran of the Spanish-American War; fellow of the International College of Surgeons and the American College of Surgeons; died June 6, aged 81.

Wilkins, John Peter, Mound, Minn.; the Hahnemann Medical College and Hospital, Chicago, 1905; veteran of the Spanish-American War; member of the school board; local health officer; surgeon for the Great Northern Railway Company; died in the Veterans Administration Hospital, Minneapolis, June 4, aged 81, of leukemia.

Wojcicki, Henry Telesfor ⊕ Fairhaven, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1933; served on the staff of St. Luke's Hospital in New Bedford; died June 6, aged 53.

FOREIGN LETTERS

INDIA

Hepatic Lipids After Partial Hepatectomy.—Chatterji and Chatterjee (*Bulletin of the Calcutta School of Tropical Medicine*, April, 1956) stated that the normal liver contains about 4% total lipids as phospholipid and neutral fat in the proportion of 3:1. After partial hepatectomy there is extensive deposition of phospholipids, cholesterol, and neutral fat in the remaining portion of the liver. The authors investigated the effect of adrenalectomy on the development of fatty liver after 48 hours of partial hepatectomy. Six albino rats were subjected to bilateral adrenalectomy under anesthesia with ether. They were then put on their usual diet. Seven days later 75% of the liver was removed under anesthesia with ether from the adrenalectomized rats as well as from six normal rats. After another 48 hours all of them were killed and total lipid content of the liver at operation and at autopsy determined. The deposition of fat in the remnant of liver in adrenalectomized rats was less than that in normal rats.

Histoplasmosis.—Patients who show signs of lung infiltration but have a negative tuberculin test are frequently seen. Sen and Ghosh have studied the incidence of histoplasmosis in 4,855 such patients (*Indian Journal of Tuberculosis*, June, 1956). In addition to history and clinical examination, fluoroscopy was done and skiagrams were taken if indicated. All patients were tested with tuberculin. Simultaneously and on the same forearm, 0.1 cc. of a 1% solution of histoplasmin was injected intracutaneously. The time of reading and standard of reaction were the same as those of the tuberculin test. Sputum samples of patients who had a positive histoplasmin test were examined for Histoplasma capsulatum. Biopsy specimens of enlarged lymph nodes and skin lesions were examined for H. capsulatum in some cases. In a few cases sternal marrow aspirations were made for the same purpose. Sputum from all patients was examined for tubercle bacilli. Twenty-six of the patients had a positive histoplasmin test, 3,881 had a positive tuberculin test, 33 had a positive reaction to both tests, and 915 had a negative reaction to both. Of the 26 who reacted to histoplasmin, 14 had pulmonary calcification, 3 had pulmonary infiltration, 8 had no definite lung infiltration or calcification, and one had a large mediastinal shadow on the right side. No H. capsulatum could be isolated from any of these patients.

Imidazoline for Hemiplegia.—A. L. Annamalal reported the results of treatment of 50 hemiplegic patients with 2-benzylimidazoline hydrochloride in the *Journal of the Indian Medical Association* (July, 1956). The drug is a synthetic sympathicolytic compound with a histamine-like component and a component that is present in epinephrine. It appears to exert its action by reversing the action of adrenergic drugs and has been used extensively in the treatment of peripheral vascular disorders. The rationale of this therapy in hemiplegia is the same as that of stellate ganglion block. Intravenous injections of 10 mg. of the drug were given twice daily till there was appreciable improvement, which took about three days. Later it was given only once a day. The patient could walk after the fifth or sixth injection. Injections were continued until a total of 300 mg. had been given. This was followed by oral medication. The response was good in patients with inflammatory conditions or syphilis and in thrombosis occurring in young persons with hypertension. In patients with arteriosclerosis the response was slow but gratifying. Some of the toxic reactions and side-effects noticed were excessive salivation, profuse sweating on the paralyzed side, transient edema on the affected side, gastric irritation, and hiccup. Hiccup was the only reason for discontinuance of the drug.

Liver Biopsy in Intestinal Amebiasis.—Chaudhari and Saha (*Bulletin of the Calcutta School of Tropical Medicine*, April, 1956) stated that the liver is the commonest extracolonic site of amebic infection, but the factors that cause hepatic lesions in one patient and not in another are not known. There is little correlation between the degree of clinical activity of intestinal amebiasis and the likelihood of invasion of the liver. Nutritional disturbances leading to liver damage may predispose to amebic invasion. The authors studied liver biopsy specimens from 15 patients with active amebic dysentery. The duration of the disease ranged from 15 days to eight months. On admission all but one had diarrhea with mucus and blood in the stools. Fourteen patients had had one or more attacks of dysentery in the past. Vegetative forms of Endameba histolytica were found in all patients. The liver was enlarged in nine patients, none of whom had a past history of malaria or infectious hepatitis. No specific antiamebic treatment was given in the hospital before the liver biopsy was performed. The commonest change was round cell infiltration of the periportal areas. A slight increase of portal connective tissue and patchy fibrosis were present in about half the patients. Parenchymatous degeneration of varying degree was present in eight. A few areas of focal necrosis with round cell infiltration were found in two. Four showed slight fatty changes. Brown granular pigment that did not give a positive reaction for iron was frequently present. In seven patients there were varying degrees of hyperactivity of Kupffer's cells. Repeated examinations failed to reveal amebas in any of the specimens.

Portal Circulation.—The portal venous system can be outlined by injecting a radiopaque dye through the spleen. Berry and coworkers used this technique to investigate the state of portal circulation in 18 patients (*Journal of the Association of Physicians in India*, April, 1956). A 50% iodopyracet injection was given, and liver function tests, radiological examination for esophageal varices, liver biopsy, esophagoscopy, examination of ascitic fluid when present, and measurement of intrasplenic pressure were performed. No serious untoward effects were noticed after the splenic venography; two patients vomited, and a third complained of slight pain in the left side of the chest. Splenic venography is the easiest means of diagnosis of the presence of portal hypertension and its extent and is useful in studying patients with ascites of unknown origin. It is also of use in the investigation of gastrointestinal bleeding when the cause is not obvious. It can be a useful aid in following the patient's progress after ligation of the hepatic or splenic artery for portal hypertension. It may be used prior to postcaval shunt to demonstrate the patency and size of the veins to be used for the anastomosis. It is a safe method for differentiating portal hypertension due to extrahepatic or intrahepatic obstruction. It has been used in cases of splenomegaly of unknown origin for diagnosis and for diagnosis of abdominal tumors. It may be used in diagnosing congenital anomalies of the portal venous system and metastases in the liver. Involvement of splenic or portal veins in carcinoma of the head of the pancreas may be demonstrated preoperatively by its use. It may be of value in the prognosis of portal cirrhosis. Demonstration of a normal intrahepatic pattern of the portal tree should help in the differential diagnosis of hepatic enlargements of unknown origin. The method is safe, useful, and reliable.

Changes in Renal Glomeruli in Eclampsia.—G. P. Sharma in *Journal of the Indian Medical Association* for June 16, 1956, reported a study of the kidneys of two patients who died of eclampsia. The basement membrane of the glomerular capillary walls was not thickened. Thickening of the capillary wall in this disease is due to swelling of cytoplasmic extensions of the epithelial cells and of the endothelial cells along both surfaces of the basement membrane. Ischemia is due to occlusion of the lumens of the capillaries by excessive swelling of the endothelial cells. The development in the capillary lumens of fibrils similar to those found in diffuse glomerulonephritis has been described

---

The items in these letters are contributed by regular correspondents in the various countries.

Renal failure in eclampsia appears to be due to swelling of both the endothelial and epithelial cells of the glomerular capillary loops and subsequent glomerular ischemia and diminished filtration. Proteinuria in eclampsia appears to be the result of hypoxic or anoxic damage of the capillary walls.

PERU

Treatment of Fleshy Moles.—Dr. Bazul favors active treatment of fleshy moles, as it averts hemorrhage and septicemia. He reports a series of 14 patients treated by means of curettage and pituitary extract (*Ginecologia y obstetricia*, volume 2, number 1, 1956). As soon as the diagnosis is made, therapeutic abortion should be attempted. If the metrorrhagia is copious, a suitable dilatation with Heger's dilators must be attained prior to curettage. If abortion has already started, it must be allowed to proceed unimpeded, and, when completed, 24 hours must elapse before performing curettage, though oxytocic drugs may be given in the meantime to strengthen the uterine walls. A similar approach should be adopted for incomplete abortion with mild hemorrhage, but, if the miscarriage is accompanied by severe hemorrhage, it is preferable to stimulate the uterine muscular contractions with posterior pituitary injection given parenterally as well as manual expression, since both these procedures favor the expulsion of the moles, reduce the capacity of the uterus, and permit the ultimate performance of curettage. Curets and placental forceps must be used with the utmost caution due to the danger of perforating the uterus. In the present series, toxemia of pregnancy was a predominant feature in five patients. In the remainder the chief symptom was profuse hemorrhage with resultant severe anemia, which in one patient was fatal. In a follow-up period of at least two years, no choriocarcinoma developed.

Endometrial Hyperplasia.—In the same issue of *Ginecologia y obstetricia*, Dr. Gordillo Delboy states that it is not possible to show a causative relationship between the different grades of endometrial hyperplasia and uterine adenocarcinoma. He reviewed 1,087 endometrial smears and 642 clinical records and concluded that no definite relationship existed between the grade of hyperplasia and the age of the patient. Although most patients were between the ages of 35 and 50, a few were just starting to menstruate and a slightly larger group had passed the menopause. The less severe grades of hyperplasia were by far the commonest. Women with endometrial changes usually have atypical menses and ill-defined menstrual cycles, especially if the hyperplasia is of advanced grade. In the author's series only 5.76% of the women had normal menses, and in none was the duration of the menses shorter than 10 days. There was no significant relationship between infertility, abortion, and dysmenorrhea and hyperplasia of any grade. In 150 women the endometrial hyperplasia followed infertility, and in 98 both were of the same duration. Dysmenorrhea was complained of by 44.28% of the women.

In this series 166 women had suffered at some time from varying gynecologic disorders, 80 from general diseases, 43 from endocrinopathies, and 8 from psychoneurotic disturbances, but there was no relationship between any of these conditions and the grades of hyperplasia. Histologically the pattern shown by the nuclear chromatin is the most characteristic feature, regardless of the grade of hyperplasia, and reflects marked estrogenic stimulations. In 17% of the patients a secretory-granular endometrial picture was observed along with the abnormal proliferative findings typical of the hyperplasia. This was probably produced by the luteinizing factor released by the hypophysis due to an excess of estrogens arresting the production of follicle-stimulating hormone.

Latent Genital Tuberculosis.—Peru is passing through a period of mass tuberculization, mainly in its cities. The mortality rate for the whole country is about 3%. Campaigns aimed at increasing the early diagnosis of the disease are being initiated. Dr. Ascenzo Cabello, in the same issue of *Ginecologia y obstetricia*, states that the diagnosis of genital tuberculosis in women has been neglected, most of the cases being missed. The author found 9 patients with latent genital tuberculosis in a group of 110 private patients who complained of sterility. Partial or total tubal obstruction with neither previous history of gonorrhea nor inflammatory antecedents was found in eight of the nine persons with detected cases. Hypermenorrhea was noticed by four and either amenorrhea or oligomenorrhea by three of the patients. Tuberculosis in organs other than the genitals was found in three and genital hypoplasia in two. Biopsy of the endometrium is the best procedure for the diagnosis of the condition. In all the patients medical management and psychotherapy were started soon after the diagnosis was made, and 37 also underwent operation, but none were able to become pregnant. Although histological findings in the endometrium returned to normal in four of the five patients who were followed, they remained under close medical supervision, as a negative biopsy does not rule out the existence of active lesions.

New Naval Hospital.—A new naval hospital, opened in July, is located between Lima and Callao and was built along lines similar to those of the American Naval Hospital in Beaufort, Calif. Its anchor-shaped building has a five-story main body with two three-story wings and a total capacity of 302 beds, but, when future expansions are completed, it will accommodate 722 patients. Rear admirals Milton E. Miles, representing the Department of Naval Operations, Charles W. Wilkins, director of Pan-American affairs in the same department, and Bartholomew W. Hogan, chief of the Bureau of Medicine and Surgery, all of the U. S. Navy, attended the opening ceremonies.

UNITED KINGDOM

Home Care and Nursing.—Dr. G. E. Godber, in a symposium in the July issue of *The Practitioner*, points out that the health service depends primarily on comprehensive home care, with hospital and specialist services only for diagnosis and treatment of illness outside the scope of the family physician and his supporting team. It should not be regarded as a service for hospital inpatients supported by facilities for home care. He draws attention to the fact that in England and Wales the hospital admission rate per 1,000 of population in 1952 was only 77.7, compared with 118.5 in Sweden and 106 in Denmark. This disparity is attributed, in part, to the greater range of home care made possible by the assistance a highly developed outpatient service can give to the family physician and his supporting team. The growth of consultative outpatient work is the most striking development in hospital services since the end of the war. Outpatient services are now more rigidly restricted to their proper consultative functions, and their further development has provided consultation in the patient's home when medical considerations forbid transport to the hospital. One person in every 12 is admitted to the hospital each year, and nearly one person in every 6 attends the hospital outpatient service; but family physicians see each of their patients on an average five times a year, home nurses make one visit for every 2 members of the population, and health visitors make one visit for every 4. On any given weekday, of every 1,000 persons, 10 will be in the hospital, 3 will have attended the outpatient clinics, 16 will have seen their family physician, and 3 will have been visited by a home nurse or health visitor. Home care depends primarily on wives, mothers, and daughters, not on physicians and nurses, whose function is to supplement, not to replace, the contribution of the family. The scope of home care is determined as much by the capacity of the family as by medical considerations.

In the past 25 years there has been a steady decrease in the proportion of home confinements, until now it is little more than 33% of the total number. Although the official policy has been to maintain a domiciliary midwifery service insofar as medical and social conditions permit, in London less than a quarter, and in some towns barely a tenth, of the births occur at home.

Home-Care Project.—Dr. Reginald Lightwood gives an account of the St. Mary's home-care project, which was instituted in April, 1954. The primary aim was to enable the hospital staff to cooperate more closely with family physicians by giving them professional support and by providing a diagnostic and th [illegible] peutic service. By such arrange [illegible] family physicia [illegible] share in the clinical responsibili [illegible] losing it, and also kept in touch wi [illegible] ent [illegible] The sec [illegible] was the avoidance of admission of children to the hospital except when necessary. At St. Mary's Hospital, before the home-care project started, it was estimated that 25% of the children in the hospital could have been treated at home if the family physicians had had the facilities and experience required, and there were other children whose stay could have been shortened. The third aim was to cut the high cost of inpatient treatment by providing a cheaper alternative that nevertheless afforded a standard of care as high as that in a hospital ward.

The basic feature of the project is a mobile team, based at the hospital, and consisting of pediatricians and nurses with pediatric training. When a family physician wants the help of the team, he telephones the home-care office at the hospital, and one of the pediatricians goes with him to the patient's home. If it is found that the child does not need inpatient treatment, specimens are collected for any necessary tests, and treatment is started at once. The results of the tests are reported to the family physician promptly, and he remains in charge of the patient, the team being at his disposal if needed. The nurse, responsible for organizing the work of her two colleagues, attends the consultation and can then see what nursing care will be required. Any necessary equipment can be brought from the hospital to the home. A home-care project such as this is likely to be more valuable in an urban area than in a more sparsely populated one. Most of the visits have been made within an area of two miles from the hospital. The staff can comfortably handle a case load of 25 to 30 children, and during the initial period of two years their help has been given in the treatment of 582 children. Most of the patients have been referred by family physicians. A smaller number have been transferred from hospital to home care for the completion of treatment, and a few have come from casualty and outpatient departments after the family physician has been consulted. The technique of home care is suitable for most nonsurgical conditions met with in a children's ward, digestive disorders and feeding disturbances in infants, most of the ordinary infectious diseases, and many types of chronic illnesses, including certain cases of tuberculosis.

Care of Maladjusted Children.—Prof. W. S. Craig, writing on home care of the maladjusted child, states that children of all ages cause parental anxiety because of behavior disorders that have no organic basis and arise from maladjustment within the household. To designate these children as maladjusted is misleading, because it ignores the real source of the trouble. Craig's article consists of a review of his findings in a study of 200 children between 3 and 14 years of age. Unhappiness of long duration was characteristic of most of the households. In 51 households tension could be traced to exhaustion of the mother resulting from combining outside employment and domestic duties. When both parents were working, home had little significance to many children beyond that of a place to sleep. A number of other examples were encountered of children who knew little of satisfying home life and still less of true maternal love because of the mother's absorption in social activities. Two distressing cases concerned children whose fathers were ministers and whose mothers undertook an inordinate amount of parochial work in addition to household duties although handicapped by lack of domestic help and financial resources. A nursemaid or more often a series of nursemaids is not an adequate substitute for an absent mother in homes more economically favored. Management of these cases consists largely and sometimes solely in rectifying influences within the home—influences that the family physician is in a position to recognize and often to remedy.

Feeding Habits of Tsetse Flies.—The annual report of the Lister Institute of Preventive Medicine for 1955-1956 includes a study of the natural feeding habits of tsetse flies. The blood meals of about 2,000 flies caught in 17 different localities in the Sudan, Uganda, Tanganyika, Kenya, and Southern Rhodesia were identified serologically. The species studied were Glossina morsitans, G. swynnertoni, G. pallidipes, G. palpalis, G. brevipalpis, G. austeni, and G. longipennis. Each species has characteristic feeding habits; in some instances these were due to differences in habitat. Thus, the riverine G. palpalis feeds largely on reptiles, although it feeds also on birds and on some of the mammals that come to drink at the water edge. The savannah species (G. morsitans and G. swynnertoni) depend on the wart hog for half their food supply, which is surprising, since it was thought that ruminants were their main source of food. Other mammals such as rhinoceros and elephant are commonly used by the flies, whereas monkeys, baboons, and birds are not often used. G. pallidipes feeds chiefly on bushbuck. In Zanzibar, the main host of G. austeni was the bushpig, which is an interesting finding, as this fly is a crepuscular feeder and the bushpig a creature of nocturnal habits. None of the tsetse flies fed on hartebeest, topi, wildebeest, or zebra, though in some localities the hartebeest and zebra were numerous and readily available to the flies. Similarly, impala, thought to be the main source of food, provided only 0.8% of the feedings of G. morsitans, although there were numerous large herds in the neighborhood.

Health Control Regulations.—As a result of recent administrative arrangements, the seven member states of the Western European Union now form a single territory for health control of sea and air traffic. This is an extension of the scheme operated by the five-power Brussels Treaty Organization. Under the new arrangements, health control regulations at airports no longer apply to aircraft coming from airports of any of the member countries. On the other hand, each country may apply to an aircraft arriving from outside the Union any measures of health control it considers appropriate. In the case of sea traffic, the Maritime Declaration of Health is no longer required from member countries' vessels plying only between those ports of the seven countries included in the scheme.

Automobiles and Air Pollution.—At a meeting of the Royal Society of Health, Dr. Arnold Fitton of the Fuel Research Station reported that in 1954 the amounts of smoke, sulfur dioxide, and carbon monoxide discharged from the use of 5.9 metric tons of gasoline and 1.4 metric tons of diesel oil in road vehicles were 0.015, 0.02, and 4 metric tons of diesel oil in road corresponding figures for the 200 metric tons of coal burned were 2, 5, and 20. Thus, the total air pollution by exhaust gases was small compared with that by coal-burning, but the former was emitted in the street at a low level and had, therefore, little time for dispersal before being inhaled. The greatest difference between gasoline and diesel engines was in the carbon monoxide content, which was about 4% in the former and 0.1% in the latter. In gasoline-driven vehicles, the carbon monoxide content was at a maximum when the motor was idling. Practically no benzpyrene was detected at gasoline engine loads exceeding 50%, and in efficiently run diesel engines only a trace was found. As long-term methods of reducing pollution from exhaust gases, control of the air-fuel ratio to give complete combustion; catalytic or direct combustion of exhaust gases; better combustion chamber design; use of filters, absorbers, and adsorbers; and better dispersion of exhaust were recommended.

Dr. E. T. Wilkins of the Fuel Research Station stated that, compared with the three polluants, grit, smoke, and sulfur, which amounted to 1, 2 and 5 metric tons, respectively, each year, carbon monoxide pollution totaled about 24 metric tons, of which 10 were from industrial chimneys, 10 from domestic appliances, and 4 from automobile exhausts. The average concentration of carbon monoxide in the air of the streets of London in 1955 was 15 ppm, the highest figures being obtained in Oxford Circus and Regent Street (52 and 40 ppm respectively). In the smog of January, 1956, the figure rose to 50 ppm in London, but in Salford, Lancashire, it rose to 80 ppm. In streets there is a steady decrease in concentration with increasing height to about one-third of the ground level rate at 100 ft. Assessments of the toxicity of carbon monoxide at various concentrations varied. On the average, a pedestrian may experience a just perceptible effect after exposure of four to eight hours to a concentration of 50 ppm. At 100 ppm there would be slight headache and shortness of breath after two or three hours. In view of the marked individual variation, the hazard of air pollution in our streets should be assessed from the reaction of the more susceptible persons.

Dr. Burgess, chief chemist to the London County Council reported concentrations of up to 460 ppm of carbon monoxide in the Blackwall and Rotherhithe Tunnels. Dr. Lather, of the Medical Research Council, reported that an analysis of the air breathed by people working in close proximity to the source of gas emission in a London transit garage containing 250 diesel buses had failed to show any increase in the benzpyrene content as compared with the air outside.

CORRESPONDENCE

FOCAL EMPHYSEMA

To the Editor:—The description of "focal emphysema" as a distinct pathological entity in coal workers is associated with the Welsh National School of Medicine. The existence of this form of emphysema, characteristic of the simple dust lesion in coal workers, has been confirmed by a number of pathologists in different countries. Your correspondents, Drs. Mayer, Rappaport, and Schepers (*J. A. M. A.* 160:230 [Jan. 21] 1956), are the only ones we have encountered who have misinterpreted our descriptions (Gough, J.: *J. Path. & Bact.* 51:277, 1940; Report of Advisory Committee on Treatment and Rehabilitation of Miners in Wales Region Suffering from Pneumoconiosis, London, His Majesty's Stationery Office, 1944, p. 17; *Occup. Med.* 4:86, 1947. Heppleston, A. G.: *J. Path. & Bact.* 59:453, 1947; *A. M. A. Arch. Indust. Hyg.* 4:270 [Sept.] 1951; *J. Path. & Bact.* 66:235, 1953; ibid. 67:51, 1954) and those of Williams (Report of Advisory Committee on Treatment and Rehabilitation of Miners in Wales Region Suffering from Pneumoconiosos, London, His Majesty's Stationery Office, 1944, p. 18), to which, however, they make no specific reference.

Emphysema is a term implying enlargement of air-containing spaces or inflation due to the presence of air. We are not concerned here with interstitial emphysema of the lung. Pulmonary emphysema may affect all segments of the bronchiolar tree bearing alveoli, including respiratory bronchioles. As original observers, we are entitled to our definition of focal emphysema as "a group of dilated respiratory bronchioles occurring in and around a focus of dust such as coal." French pathologists, confirming our work, make a slight alteration and use the term *emphysème perifocal.* This implies that the dilated air passages are limited to the periphery of the dust focus, and we therefore prefer our original term, since enlarged airways also occur within the focus of dust. If there is no dust focus, then, by our definition and descriptions, the condition is not focal emphysema. Focal emphysema is not restricted to coal workers but occurs in hematite, graphite, and foundry workers and also after inhalation of purified carbon. The fully formed classic silicotic nodule, although it develops at the same site as the coal dust lesion, is not associated with focal emphysema as defined above. The fibrosis of the simple silicotic nodule surrounds and constricts respiratory bronchioles (Heppleston, A. G.: *J. Path. & Bact.* 66:235, 1953. Simson, F. W.: ibid. 40:37, 1935). The air spaces around some silicotic nodules, however, may be somewhat enlarged, but these spaces develop from various segments of the airway and represent a vicarious emphysema such as may occur around any pulmonary scar as it contracts. It is this localized form of vicarious emphysema that Kuschner (*A. M. A. Arch. Indust. Health* 13:147 [Feb.] 1956) describes as focal emphysema. Such an application of the term appears to be uncommon. In Europe the term focal emphysema is now used in the specific sense, and it would be of obvious advantage if such usage were universal. The term focal emphysema does not appear in Dorland's American Illustrated Medical Dictionary, so it can justifiably be used specifically in the United States.

Mayer, Rappaport, and Schepers consider that inhaled dust may cause other forms of emphysema than the focal variety. Anatomic studies in man (Heppleston, A. G.: *J. Path. & Bact.* 66:235, 1953) reveal that nonindustrial generalized vesicular emphysema, whether in older persons or not, is characterized by enlargement of alveolar ducts and alveolar sacs at the expense of alveolar spaces. These changes occur in the absence of dust, and respiratory bronchioles are little, if at all, involved. Generalized vesicular emphysema sometimes coexists with focal emphysema, but this association does not necessarily mean a common causation. Localized destruction of lung tissue occurs in some cases of generalized vesicular emphysema, giving rise to bullae, that is, spaces from which parenchyma has disappeared and into which air passages open irregularly. Whether the generalized form of emphysema is commoner in industrial workers than in the rest of the population has not been proved, but the question certainly merits inquiry.

There is, moreover, another nonindustrial emphysematous state from which focal emphysema must be distinguished, namely, centrilobular emphysema (Gough, J.; Fletcher, C. M.; Gibson, J. C., and Oldham, P. D.: *Proc. Roy. Soc. Med.* 45:576, 1952). In this condition groups of dilated respiratory bronchioles, usually the more distal orders (Leopold, J. G.: Personal communication to the authors), occur toward the centers of secondary lobules, whereas generalized vesicular emphysema affects alveolar ducts and alveolar sacs (Heppleston, A. G.: *J. Path. & Bact.* 66:235, 1953). Centrilobular emphysema is not necessarily associated with dust collection, occurring in both miners and the nonindustrial population, but it is associated with chronic inflammation of parent nonrespiratory or respiratory bronchioles (Leopold, J. G.: Personal communication to the authors. Spain, D. M., and Kaufmann, G.: *Am. Rev. Tuberc.* 68:24, 1953). The chronic bronchiolitis is most likely the primary change. A distinction must also be drawn between focal emphysema and small tension cysts of the lung (Heppleston, A. G.: *J. Path. & Bact.* 66:235, 1953). Schepers (*A. M. A. Arch. Indust. Health* 12:306 [Sept.] 1955) has produced in guinea pigs a condition that may correspond with centrilobular emphysema and has mistakenly called it focal emphysema. He has, furthermore, produced this change by a highly artificial method, namely, by exposure to an aerosol of rare earth fluorides. It is quite unjustifiable to interpret the changes in the lungs of coal workers on the basis of these experiments, the conditions of which cannot be considered as remotely similar to the working environment in coal mines. A much more rational experimental approach is to expose animals in coal mines to the same atmosphere as is breathed by the miners. By this method it has proved possible to demonstrate the evolution of focal emphysema after the formation of coal dust foci (Heppleston, A. G.: *J. Path. & Bact.* 67:349, 1954).

Schepers has written to one of us (A. G. H.) suggesting that in coal miners emphysema occurs first and then coal dust is deposited between the emphysematous spaces. Our studies on the pathogenesis of coal dust pneumonoconiosis in man (Heppleston, A. G.: *J. Path. & Bact.* 59:953, 1947; ibid. 66:235, 1953; ibid. 67:51, 1954) and in animals (Heppleston, A. G.: *J. Path. & Bact.* 67:349, 1954) are strongly opposed to this view. Furthermore, we have available for examination, by anyone who wishes, whole lung sections from thousands of coal workers of ages ranging from 17 to 80 years. The young miners show collections of dust with no emphysema. As the age increases, the incidence of focal emphysema increases also. There is no doubt that the formation of dust foci precedes the development of focal emphysema.

We agree with your correspondents that the degree of clinical and physiological disability in simple pneumonoconiosis does not correlate with the radiological appearances. This is only to be expected in coal workers and similar employees, since the radiological opacities reflect the presence of dust foci and may give no indication of either the existence or the degree of focal emphysema or of generalized vesicular emphysema (Gough, J.; James,

W. R. L., and Wentworth, J. E.: *J. Fac. Radiologists* 1:28, 1949). Cases of pneumonoconiosis are frequently classified on the basis of their radiological features for diagnostic and investigatory purposes. There is, however, a growing opinion in Great Britain that respiratory disability developing in coal workers is not proportional to the radiological changes and may be present with a normal chest radiograph (Chest Radiography in Pneumonoconiosis, *Lancet* 1:326, 1956. Gilson, J. C., and Hugh-Jones, P.: Lung Function in Coalworkers' Pneumonoconiosis, Medical Research Council Special Report Series no. 290, 1955).

Your correspondents' letter arose from an editorial by Dr. O. A. Sander (*J. A. M. A.* 158:1526 [Aug. 27] 1955). Regarding focal emphysema, Sander asked why it occurred in coal workers, hematite miners, foundry workers, and Kolar gold miners but not in the siderosis of welders. We believe that focal emphysema is due to mechanical overloading of the lung with relatively inert dust and therefore that a comparison of the quantity of dust in the different occupations should be made. Sander apparently has access to cases of siderosis, and it would be of value if he could determine the weight of iron oxide in these lungs to see whether it compares quantitatively with 30 gm. or more of coal dust often found in colliers' lungs showing simple pneumonoconiosis. In the patients with tin oxide pneumonoconiosis whom we have examined, the degree of focal emphysema is slight but the weight of dust in the lungs is less than one-fiftieth of that found in coal workers with well-marked simple pneumonoconiosis. Dr. G. Nagelschmidt has drawn our attention to the great difference in the quantity of dust in different forms of pneumonoconiosis. Compared with coal, a small amount of iron and an even smaller amount of tin will give rise to similar radiopacity. We recognized that the amount of dust is not the only factor in the genesis of focal emphysema. The degree to which the smooth muscle of the respiratory bronchioles is developed and the extent to which dust accumulation interferes with muscular action will also influence the severity of focal emphysema (Heppleston, A. G.: *J. Path. & Bact.* 67:51, 1954). Sander pleads for the study of emphysema by a third dimensional technique. We support him and would emphasize that many of our results are based upon e extensive use of serial sections (Heppleston, A. G.: *J. Path. Bact.* 66:235, 1953; ibid. 67:349, 1954. Leopold, J. G.: Personal communication to the authors); from them a cinephotographic technique has been evolved to demonstrate the lung changes in depth (Heppleston, A. G.: *Lab. Invest.* 4:374, 1955).

BASAL METABOLIC RATE

To the Editor:—During the past 17 years we have done several thousand pulmonary function studies by spirometric methods and with these we have obtained as many determinations of the basal metabolic rate. Again and again we have noticed the tendency of the basal metabolic rate to be low when calculated by the "accepted" standards. What are the accepted standards? At present there are three slightly different standards in use: the Aub and DuBois standards (1917), modified by Boothby and Sandiford (1929); the Harris and Benedict standards (1919); and the Mayo Clinic standards of Boothby, Berkson, and Dunn (1936). The normal basal metabolic rate is usually considered to range from −10 to +10% when compared with any of these standards.

Observations similar to ours have been made before. DuBois and Chambers (*J. A. M. A.* 119:1183 [Aug. 8] 1942) found that the old standards were too high and that rates in most normal persons come within +5 and −20% of the so-called standard. Keys (*J. A. M. A.* 142:333 [Feb. 4] 1950) says: "The excellent basal metabolism standards of the Mayo Clinic [Boothby, Berkson, and Dunn] overestimate the true basal metabolism by something like 10 per cent." Robertson and Reid (*Lancet* 1:940, 1952) state: "It became apparent that either the standards of Aub and DuBois were too high for people in this country, or that there were some differences in technique in measuring the BMR or both." These authors found the standards for normal people in England to be 10% less than the Boothby-Sandiford standards of 1929 and 9% less than the Mayo Clinic normal standards of 1936. In spite of these observations, most textbooks still accept the old standards. Best and Taylor (Physiological Basis of Medical Practice, ed. 6, Baltimore, Williams & Wilkins Company, 1955) refer to Boothby and Sandiford (1920) and to Boothby (1924). Wakefield (Clinical Diagnosis, New York, Appleton-Century-Crofts, 1955) quotes the standards of Boothby and Sandiford (1924). West and Todd (Textbook of Biochemistry, New York, the Macmillan Company, 1951) refer to the standard values of Boothby, Berkson, and Dunn (1936). Fulton (Textbook of Physiology, ed. 16, Philadelphia, W. B. Saunders Company, 1950) accepts the DuBois normal standards as modified by Boothby and Sandiford. Bray (Clinical Laboratory Methods, St. Louis, C. V. Mosby Company, 1951) reproduces the DuBois normal standards as modified by Boothby and Sandiford. This is only a small example of a large number of books that can be quoted.

The basal metabolism test apparatus used in the United States are supplied with "normal standards," mostly the standards of 1936. But different companies recommend various standards—differing by a small percentage from each other—for their machines. In summary we wish to say that the old basal metabolism standards are too high and different standards are used in different laboratories. We would like to make a plea for establishing new standards that can and should be used with every basal metabolism test apparatus in every laboratory.

SALICYLATES AND URINARY CALCULI

To the Editor:—On the basis of recently published reports (Prien, E.L., and Walker, B.S.: Salicylate Therapy of Recurrent Calcium Urolithiasis, *New England J. Med.* 253:446-451 [Sept. 15] 1955; Salicylamide and Acetylsalicylic Acid in Recurrent Urolithiasis, *J.A.M.A.* 160:355-360 [Feb. 4] 1956), various drug companies are currently conducting an extensive mail campaign advertising their particular brand of salicylates for prevention and treatment of urinary calculi. It should be pointed out that this group of drugs was recommended for use only in the presence of calcium-containing calculi. Their use in the management of patients with recurrent uric acid calculi is contraindicated because of the well-known property of salicylates to increase the urinary excretion of uric acid. Before beginning salicylate therapy, every effort should be made, including stone analysis, to determine the chemical nature of the calculi being formed.

TREATMENT OF HERPES ZOSTER

To the Editor:—The treatment of herpes zoster has a perennial popularity in medical writings. Because it is a disease that subsides spontaneously and because its duration may vary from several days to a number of weeks in different patients, the response to a therapeutic agent is difficult to assess. In recent textbooks (Blank, H., and Rake, G.: Viral and Rickettsial Diseases of the Skin, Eye and Mucous Membranes of Man, Boston, Little, Brown & Company, 1955) it has been pointed out that, as with other viral diseases, no specific effective treatment exists. Van Blaricom and Horrax (Chronic Postherpetic Neuralgia, *J. A. M. A.* 161:511 [June 9] 1956) in their recent article have effectively emphasized the variable results to be expected in treating postherpetic neuralgia with even the most modern forms of neurosurgery. All would agree with their suggestion that prevention of the neuralgia by effective treatment during the acute stage of the herpes zoster would be most desirable. As indicated, however, no such treatment is known, and their admonition to use Aureomycin, Chloromycetin, and Pituitrin is contradicted by available evidence. In all of the series of patients reported it has been impossible to show that any therapeutic agent was effective when results were compared with use of a placebo in a properly controlled study. Because this is a point worthy of emphasis to the profession, several pertinent reports are summarized in the accompanying table.

Summary of Reports on Effect of Therapeutic Agents in Treatment of Herpes Zoster

Authors	Drugs	Controls	No. of Patients	Conclusions
Schaffer and Svendsen: Acta dermat.-venereol. 32:184, 1952.	Aureomycin Chloromycetin	Lactose capsules	46	"No difference in the course of the disease in the experimental and control group, neither with regard to the duration of the skin lesion nor the neuralgias"
Kass, Aycock, and Finland: New England J. Med. 246:167, 1952.	Aureomycin Chloramphenicol	Empirin compound	72	"No measurable effect of the use of Aureomycin or chloramphenicol as compared with the use of a simple analgesic"
Carter: Brit. M. J. 1:987, 1951.	Aureomycin	Glucose capsules	44	"No significant difference between the groups in respect of pain, paresthesias, or the appearance of fresh herpetic lesions"
Simons: Dermatologica 103:109, 1951.	Pituitrin	Saline injections	57	"The spontaneous healing could hardly be influenced by injections of saline, antiphyretics, or hypophysis extracts"

MEPROBAMATE

To the Editor:—With regard to reactions to meprobamate (Kositchek, R. J.: Reactions to Meprobamate, Correspondence Section, *J. A. M. A.* 161:644 [June 16] 1956), my colleague and I have now given this drug to more than 200 patients, including the prerelease testing that we were asked to do. We found absolutely no toxic adverse effects, except dizziness in some patients, when 400 mg. was used as a dose. We therefore now prescribe 200 mg. (½ tablet) to be taken after meals and before bedtime. We have never found erythema in our patients. However, we are not under any delusion on this score; we will probably get our 2% of reactions all at one time. There is hardly a useful drug on the market that does not give this small percentage of reactions. The author of the letter dramatically states that all types of antihistamines were prescribed but to no avail. I hope this sentence is merely a figure of speech, because one wonders how many types of antihistamines can be tried in 24 hours. The latest report I have come across on meprobamate is by Thimann and Gauthier (*Quart. J. Stud. Alcohol* 17:19-23 [March] 1956). These authors emphatically state that this drug was found essentially nontoxic and that its continued use did not result in habituation or addiction. Lowell S. Selling (*J. A. M. A.* 157: 1954-1956 [April 30] 1955) reported three urticarial reactions in 187 patients. Patients with these reactions responded very well to treatment with antihistamines and the discontinuance of meprobamate therapy.

BRUCELLOSIS

To the Editor:—In the article "Chronic Localized Pulmonary Brucellosis," by Weed, Sloss, and Clagett (*J. A. M. A.* 161:1044 [July 14] 1956), it was stated that "modern reviews do not mention this manifestation of brucellosis," with a reference to the first edition of my book "Brucellosis (Undulant Fever): Clinical and Subclinical" (New York, Paul B. Hoeber, Inc,. 1941). The subject of pulmonary lesions in brucellosis, including nodular granulomas, was covered quite extensively in the second edition of this monograph, published in 1950 (pages 105-107 and 162-172).

POLIOMYELITIS IN THE UNITED KINGDOM

To the Editor:—My attention has been drawn to the figures of poliomyelitis notifications and deaths quoted in the passage commencing "Increase in Poliomyelitis," in Foreign Letters, on page 1351 of The Journal, April 14, 1956. These figures have apparently been taken from the Registrar General's Weekly Return, no. 52, 1955, and are the total numbers of uncorrected notifications and of deaths in the Great Towns during the 52 weeks of 1953, 1954, and 1955. Naturally they differ considerably from the final figures for England and Wales as a whole.

MUSEUMS OF INTEREST TO PHYSICIANS

To the Editor:—The letters of Drs. Stenn (160:1090) and Gebhard (161:643), published in The Journal in the issues of March 24 and June 16, both failed to mention the Museum of the History of Science at Florence. In spite of the fact that it is just around the corner from the Uffizi Gallery, very few people seem to know about it. The museum has many of Galileo's mathematical instruments and, among other things, a considerable collection of medieval surgical and dental instruments.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Malpractice: Doctrine of Res Ipsa Loquitur Applicable to Dentists.—This was an action for damages for injuries alleged to have been caused by the negligence of the defendant dentist during and after the extraction of a wisdom tooth. From a judgment in favor of the dentist, the plaintiff appealed to the court of appeals of Kentucky.

The plaintiff, suffering severe pain from a wisdom tooth, accompanied by great swelling, went to the defendant dentist for relief. The defendant took an x-ray, determined the position of the tooth, and proceeded to extract it, after injecting Novocain to relieve the pain. In the process the tooth shattered, but the defendant removed the splinters, packed the cavity with medicated gauze, and gave the patient a sedative. For the next three days, the plaintiff went back to the defendant and complained of much pain in the socket, which eventually spread to the arm. At the end of the third day, the plaintiff said, the defendant told him that he did not want to fool with it any more and that he was through with the case. Three weeks later, the plaintiff went to another dentist, who took an x-ray and discovered a piece of the broken tooth, about the size of the head of a kitchen match, embedded in the jaw. This dentist removed the fragment, and the plaintiff subsequently recovered from his disability.

The only bit of the plaintiff's evidence that was contradicted by the defendant was that the defendant insisted that the plaintiff's jaw was not swollen. All the rest of it stands admitted, said the court, and the plaintiff well proved the condition of his jaw before the extraction and after. The defendant testified that he had pursued the proper course and the customary practice for routine extractions, which he regarded this one to be. He testified, "If you break a root, most of the time you feel it or you hear it." He had not felt or heard any breaking of this patient's tooth. The trial court directed the verdict for the defendant at the close of the plaintiff's case on the grounds that no dentist testified that pulling a tooth, even where there is a swollen condition, was improper medical practice and that, on the contrary, the defendant's professional testimony was that he had pursued the proper practice.

Several of our opinions, said the court of appeals, contain the broad statement that "in malpractice suits against dentists such proof can only be established by the testimony of experts skilled the dental profession. They are the only witnesses who are qualified to testify as to whether there was negligence in the method of treatment." But, there is a limitation on the rule that expert testimony is essential to support a cause of action for malpractice when the common knowledge or experience of laymen is extensive enough to recognize or to infer negligence from the facts.

Some features of the case at bar, said the court, may be regarded as requiring opinion evidence because they are exclusively within the domain of an expert; however, the court of appeals continued to state that the fundamental fact is that this defendant dentist only partially extracted the plaintiff's tooth and left a fragment in the socket. He did not complete the operation. Although the sequence of events indicated something was wrong, the dentist callously abandoned his patient in a condition of suffering.

It is within the realm of common knowledge of laymen that to leave a part of a broken tooth in the socket, which was easily discovered by another dentist, is malpractice unless proof tending to excuse the act is introduced. This is knowledge that is not exclusively within the province of practitioners of the dental profession. A juror needs no scientific enlightenment to see at once that leaving a portion of a broken tooth in the socket can be accounted for on no other theory than negligence. Such act is somewhat analogous to leaving a foreign substance or object in a patient's body during a surgical operation. The rule of *res ipsa loquitur* generally applies in such cases.

In the case at bar there is added to the proof that a piece of the plaintiff's tooth was left in the socket the element of continued treatment with little or no effort on the part of the defendant to discover the cause and relieve his patient. Dentists are subject to the rules that govern physicians and surgeons generally, and there may be legal liability for postoperative negligence by a dentist. In this day and time, the use of x-ray apparatus by competent dentists and the information revealed through its ordinary use are so well known as to be within common knowledge and frequent experience of laymen. The defendant had such a machine and had used it before the operation but had failed to use it afterward in diagnosing and attempting to remedy the unsatisfactory condition that was so apparent When another dentist did use an x-ray apparatus, he discovered the fragment of tooth. In the circumstances shown, the jury could well believe that the failure to take x-rays after the operation was a factor to be taken into account in the over-all question of postoperative negligence without having an expert tell them so

Accordingly, the judgment of the trial court in favor of the defendant dentist was reversed. *Butts v. Watts, 290 S.W. (2) 777 (Ky., 1956).*

Insanity: Liability of Physician in Relation to Commitment Procedure.—The plaintiff filed an action for damages for malicious prosecution against the defendant physician. From a judgment for the plaintiff, the defendant appealed to the Supreme Court of Michigan.

The defendant had known the plaintiff and her family for many years and had acted as physician to various members of the family. In 1947, the plaintiff's father told the defendant that the plaintiff had threatened suicide, that she had attacked her sister and had fought her husband and father when they interfered, and that he kept his doors locked in fear of what the plaintiff might do to her mother. The plaintiff's husband, father and brother all asked the defendant's advice as to the desirability of having the plaintiff submit to a mental examination and he told them they should discuss the matter with the probate court. Subsequently the plaintiff's father signed a petition to have the plaintiff committed for a mental examination and requested the defendant to be one of the examining physicians required by statute. The defendant declined to so act. In response to a question by the probate judge, however, he stated his opinion that the plaintiff should be hospitalized for mental treatment, and wrote "9/25/47. In my opinion Mrs. Florence Nash should be hospitalized for mental treatment. /s/ Harold E. Mayne, M.D." The probate court then issued an order for a hearing to determine the plaintiff's mental condition, which order directed that the plaintiff be taken into custody 24 hours before the hearing. The plaintiff was taken into custody and was kept in jail for approximately 33 hours, following which she was released after being examined by four doctors, three of whom certified she was sane. The Supreme Court said that the only issue to decide was whether or not the defendant's signed statement was the proximate cause of the plaintiff's imprisonment.

The petition filed in the probate court, upon which the order directing the plaintiff be held was entered, was signed by virtue of section 330.21 of the Michigan Statutes, which provides: "If it shall appear, upon the certificate of two legally qualified physicians, to be necessary and essential so to do, the court may order such alleged mentally diseased person . . . to be detained until such petition can be heard and determined." Under this section, said the court, an order for temporary detention can only be made after the court has on file the certificates of two physicians certifying that it is necessary to temporarily detain the alleged insane person. There was no record in the present case that such certificates were on file before the plaintiff was detained, therefore the detention order was not in compliance with the statute. In order for there to be proximate cause, it must appear that the injury to the plaintiff was the natural and probable consequence of the defendant's wrongful or negligent act and that such consequence ought to have been foreseen, in the light of the surrounding circumstances. The plaintiff's imprisonment was not the natural and probable consequence of the defendant's signed statement, said the Supreme Court, because the defendant could not foresee, or have any reason to expect, that the probate court would issue an order contrary to the statute. He had the right to rely upon the process of the probate court being regular and proper. Therefore, concluded the court, the writing of the defendant could not be and was not the proximate cause of the plaintiff's injury. Accordingly the judgment of the lower court against the physician was reversed. *Nash v. Mayne, 65 N. W. (2d) 844 (Mich., 1954).*

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

The Present Status of Treatment of Autoimmune Hemolytic Anemia with ACTH and Cortisone. W. Dameshek and Z. D. Komninos. Blood 11:648-664 (July) 1956 [New York].

Dameshek and Komninos present observations on 43 consecutive patients with autoimmune hemolytic anemia who were initially treated with either corticotropin, ACTH-gel, cortisone, or compound F. Twenty-one of the 43 patients had the idiopathic type of the disease, whereas in the remaining patients it was associated with chronic lymphocytic leukemia in 18, disseminated lupus erythematosus in 2, periarteritis nodosa in one, and cirrhosis of the liver in one. During the early phases of this study, corticotropin was used not only while the patient was in the hospital but also for maintenance therapy at home, since at that time it was the sole available preparation. When cortisone became available for oral administration, it became the drug of choice for maintenance therapy and was used more and more as the initial medicament. Blood transfusions were given as necessary.

Intensive and presumably adequate hormonal therapy resulted in sustained and complete clinical and hematological responses in 65% of the cases. Complete and sustained remissions were more commonly obtained in the "iodiopathic" than in the "symptomatic" group. In 28% of the cases, although the response was definite, it was not so striking. The treatment failed completely in three patients. When therapy was continued after a remission, some degree of relapse developed in about two-thirds of the patients. In the remaining one-third, full clinical and hematological remission continued well after discontinuation of therapy, although the persistently positive Coombs' test indicated the possibility of future recurrence. Splenectomy was performed as the final therapeutic measure in 9 of the 43 patients and resulted in complete remissions in 6 without the further use of steroid hormones. In two patients splenectomy was followed by the development of disseminated lupus, previously undiscovered and presumably latent. The steroid hormones in adequate dosage represent a remarkably effective form of therapy for at least the initial control of most cases of autoimmune hemolytic anemia. Their use for a lengthy period is often followed by a lasting remission, and the end-results of continued steroid therapy, either alone or in some patients combined with later splenectomy, are definitely better than those of splenectomy alone. Thus, control of this rather unpredictable disease has become possible in most cases, and its management is simply a matter of varying the dosage of steroid hormones.

New Hypothesis on Congestive Heart Failure. V. Macchi and M. Corti. Minerva med. 47:1489-1493 (May 16) 1956 (In Italian) [Turin, Italy].

The authors believe that congestive heart failure and muscular fatigue have the same etiology. A decrease of metabolic energy that is probably caused by oxygen deficiency is noticed in both affections. The potential kinetic energy of the myocardial fibers is not restored, and the normal membrane cation gradient is not re-formed. An unequal concentration of sodium and potassium ions in the intracellular and extracellular fluids respectively causes the gradient that is indispensable for the contraction of the myocardial fibers. Compensation comes from an active retention of sodium and a loss of potassium in the adrenal tubules with a consequent change in the water balance. Rest, cardiotonic drugs, and any treatment that can normalize the electrolytic disturbances of the organism constitute the best therapy.

Therapeutic Trial of Total Cardiac Extract (Recosenin) in Man. K. Donat and M. Loos. München. med. Wchnschr. 98:916-918 (July 6) 1956 (In German) [Munich, Germany].

Forty-six patients with angina pectoris averaging 62 years of age were treated for at least four weeks with Recosenin, a protein-free water-soluble extract of the entire heart of healthy animals. Thirty-one patients were hospitalized and fifteen were treated ambulatorily. Circulatory disturbances in the extremities or myocardial infarction had resulted from degenerative arteriosclerotic vascular disease in some of these patients, and others had hypertension and pulmonary emphysema that placed an extra load on the heart. Most of the patients had abnormal electrocardiograms with disturbances of the stimulating period (auricular fibrillation, extrasystoles), prolonged auriculoventricular conduction, branch block, or typical lowering of the ST interval and changes of the T waves. Treatment was instituted with daily intramuscular injections of 1 or 2 cc. of the extract, and in addition 1 or 2 tablets were given three times daily. The injections were discontinued at the end of the second or third week depending on the idividual case, and oral treatment was continued up to six weeks. With the exception of two patients with generalized arteriosclerosis in whom the incidence and severity of the anginal attacks were not influenced by the cardiac extract, the anginal pain subsided in all patients after from three to five days of treatment, and the anginal attacks were less frequent or did not recur.

Disturbances of rhythm subsided in five of six patients who had been treated with the cardiac extract for from three to five days. In three of these patients changes in the terminal ventricular portion of the electrocardiogram were favorably influenced. Improvement in the duration of apnea and in vital capacity were considered as manifestations of increased cardiac performance. The average values were 21 seconds and 1,900 cc. before the institution of the therapy and 33 seconds and 2,500 cc. when the treatment was discontinued. The cardiac extract apparently exerts a favorable effect on the cardiac metabolism; this was shown by the definite improvement of the subjective anginal complaints, and by the normalization of the disturbances of rhythm and circulation particularly in patients of advanced age with degenerative disturbances of cardiac metabolism.

Pituitary Necrosis in Diabetes Mellitus. C. F. Brennan, R. G. S. Malone and J. A. Weaver. Lancet 2:12-16 (July 7) 1956 [London, England].

The authors describe the clinical and the postmortem findings in five patients with diabetes mellitus who had necrosis of the anterior lobe of the pituitary. The most important finding in three of these patients was the fairly identical pattern of healed pituitary necrosis. Plaut observed 2 patients with diabetes mellitus among 24 who had pituitary necrosis. The five cases presented here were discovered among 7,326 successive autopsies on adults, of whom 146 had suffered from diabetes mellitus. Three of these 146 had "moderate pituitary atrophy," whereas of 7,180 nondiabetic patients 13 showed such pituitary lesions. Thus the diabetic patients showed an incidence of approximately 1 in 50, as opposed to 1 in 550 in the general series. The histological changes and the clinical histories failed to throw light on the cause of the pituitary necrosis in the five patients. While two of the patients were women, neither of them had a history of postpartum hemorrhage.

With regard to the question whether partial pituitary lesions are of clinical importance, the authors quote the opinions of other investigators and suggest that, while some effective function may be maintained with a partially impaired pituitary

---

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

under ordinary circumstances, it is doubtful whether function and the emergency supply of corticotropin would be adequate under conditions of stress such as anesthesia, infection, pregnancy, or diabetic ketosis. Such a lesion might be very dangerous, since the paucity of symptoms and signs may prevent recognition of the condition. In two of the five patients with pathological evidence of partial pituitary destruction, the postmortem evidence did not disclose an adequate anatomic cause of death, and one can only speculate as to whether in those patients there was an inability to respond sufficiently to stress. The history of one of the patients is analyzed with regard to whether diabetes is more easily controlled in a patient with pituitary insufficiency and whether hypophysectomy will arrest the development of all diabetic complications. This patient seemed to exemplify the Houssay phenomenon (hypoglycemia and increase in sensitivity to insulin produced by hypophysectomy in depancreatized animals). In this patient there was a considerable increase in insulin requirement after cortisone therapy was started. Furthermore, this patient's myelopathy deteriorated during the period of hypopituitarism, which indicates that the neurological complications are not ameliorated.

Endocrine Therapy in the Aging Individual. W. H. Masters. *Obst. & Gynec. 8:61-67 (July) 1956 [New York].*

Sex-steroid replacement in the aging individual is one of the most controversial subjects in medicine today. The author is convinced that a third sex exists in our society, a neuter gender of former males and females who have reached the age of approximately 60 years. If the existence of this third sex is acknowledged, the concept of sex-steroid support is easily explained. The purpose of the technique is to develop a better-adjusted and more useful member of the neuter gender through our ever-increasing life-span. There is no evidence that sex-steroid replacement can increase longevity, and its techniques do not represent a panacea for the problems of the aging, but there is evidence that in the majority of treated patients a physical and mental resurgence of pawer potential is brought about by endocrine control of physiological functions. The entire process of growth, function, and retrogression is stimulated or controlled by the glands of internal secretion. It is therefore of vitual concern to consider the function potential of the entire humoral system during aging phases of the human body. It has become apparent that the gonads are the "Achilles' heel" of the endocrine system in the battle against the aging processes. Their functional failure is the result of a lack of organ-function reserve at a time when there is effective function in other glands. The early failure of gonadal function is due to the infinite sensitivity of these glands to the influence of other elements of the endocrinic chain or to chronic infections that may interfere with adequate ovarian or testicular hormone production and lead to a short-lived activity of the gonads.

If one accepts the usefulness of sex-steroid replacement for the aged individual, there remain the problems of techniques, including the proper time to initiate and the length of time to maintain steroid replacement. The fundamental investigative approach has been to devise steroid-replacement techniques for the support of the former female and then to transpose these techniques to the aged former male. In the aging female, estrogen, progesterone, and testosterone are given in various combinations so as to avoid vaginal bleeding, spotting, endometrial hyperplasia, or even hemorrhage. Combined estrogen-testosterone therapy is well tolerated. There has been no evidence of progressive hirsutism in the female even through three times the clinical dosage of intramuscularly given medicament presently considered effective has been maintained for as long as six months in some cases. The longe-range results include a marked increase in celular activity in the media of the blood vessels leading to the stimulated organs and a general improvement of the physical and psychological components of the individuals studied in the experiments. The treated patients are not ensured against physical and mental disability, but many have shown that they are physiologically better equipped and psychologically better oriented when treated as members of the third sex. Present consideration is directed exclusively toward treating the climacteric syndrome in either male or female by the combined-steroid-therapy technique.

Aldosteronism Associated with Adrenal Cortical Adenoma. O. B. Pratt. California Med. 85:1-6 (July) 1956 [San Francisco].

An electrolyte-regulating corticoid has been identified and given the name aldosterone. This hormone may be produced in amounts above normal in adrenal cortical tumors, in hyperplastic adrenal glands, and in normal-appearing adrenal glands. Since the description of this salt-retaining hormone by Simpson and Tait and the discovery of its chemical structure by Reichstein in 1954, 13 cases of primary aldosteronism have been reported, including one of the two presented in this paper. The clinical manifestations in the two patients observed here were almost identical. Both complained of headache, dry mouth, episodes of weakness, and polyuria. One patient had no edema, the other had minimal edema. Both had hypertension with systolic pressures around 200 mm. Hg. Serum sodium levels were in the upper-normal range or slightly higher. The urine volume was increased and the specific gravity was low in both patients. The prompt return to normal of all the clinical manifestations and laboratory findings after removal of adrenal tumors in these patients indicates that the tumors were producing a hormone that was the cause of the disturbance. The tumor in the first patient was 1 cm. in diameter, was embedded within the adrenal gland, and was well defined by a fibrous capsule. The tumor in the second patient was 3 cm. in diameter and was attached to the adrenal by a narrow pedicle.

Overproduction of aldosterone is accompanied by characteristic clinical manifestations, such as periodic severe muscular weakness, intermittent tetany, paresthesia, polyuria and polydipsia, hypertension, and absence of edema. Patients with symptoms of hypertension, muscle weakness, thirst, and polyuria should be studied with special attention to mineral metabolism. Laboratory tests reveal hypokalemia, hypernatremia, alkalosis, normal blood calcium levels, and a low ratio of sodium to potassium in sweat and saliva. There is also an increase in the exchangeable body sodium and a decrease in exchangeable body potassium. Pronounced resistance to potassium repletion by oral or parenteral administration of potassium is characteristic. Another feature is hyposthenuria that does not respond to Pitressin (beta-hypophamine). The excretion of aldosterone in the urine is increased. The urinary 17-ketosteroids and the 17-hydroxycorticoids are normal and respond to corticotropin stimulation.

True Scleroderma Kidney. R. J. Calvert and T. K. Owen. Lancet 2:19-22 (July 7) 1956 [London, England].

The history of a patient with true "scleroderma kidney," in whom uremia unexpectedly supervened five months after the clinical onset of acroscleroderma, is reported. Mild renal involvement in scleroderma was suspected when the blood urea level was normal and before cortisone treatment was begun. During this treatment moderate azotemia developed, and, although cortisone was withheld, the patient died a week later in uremia. Histological study revealed the renal vascular lesions that are specific for scleroderma, but histological evidence of other visceral lesions was not found. This suggests that the renal involvement may overshadow other visceral manifestations pathologically as well as clinically. Published reports of these poorly recognised renal lesions are briefly discussed. Such lesions in scleroderma ending in uremia, although inconstant and occasionally impure, can be pathognomonic. True scleroderma kidney is characterised by rapid destruction of kidney tissue as the result of an acute or subacute type of focal and minor renal cortical necrosis.

Observations on a Presumptive Case of Primary Aldosteronism. M. G. Crane, P. J. Vogel and K. J. Richmond. J. Lab & Clin. Med. 48:1-12 (July) 1956 [St. Louis].

A case of adrenal adenoma in a 32-year-old man is presented. This patient apparently had a case of simple essential hypertension, with two unusual complaints—dry mouth and occasional episodes of muscular weakness. The laboratory findings indicated severe hypokalemia and metabolic alkalosis. The 17-hydroxysteroids, 17-ketosteroid, and 17-ketogenic steroid excretion rates were within normal limits. The uropepsin rates were increased fourfold. The symptoms, electrolyte disturbances, and increased uropepsin excretion rate were relieved by removal of a small benign adrenal cortical adenoma. It seemed reasonable to believe that the adenoma was secreting a highly specific mineralocorticoid. Facilities were not available for determination of the specific hormone; however, the implications were that the steroid was aldosterone, a potent influence in sodium and potassium metabolism. It is a clinical feature of a new disease entity described by Conn and called aldosteronism.

ACTH and Cortisone in Agranulocytosis. J. S. Blumenthal. Minnesota Med. 39:454-456 (July) 1956 [St. Paul].

The numerous remedies recommended for the treatment of agranulocytosis, such as pentnucleotide, folic acid, vitamin B_{12}, blood, and dimercaprol (BAL), have proved largely inadequate, because they do not influence the underlying pathophysiological disturbance, namely, the arrest in the maturation of the precursors of the granulocytes in the bone marrow. Corticotropin (ACTH) and cortisone stimulate the bone marrow, and so it was natural that these hormones should be used in agranulocytosis. The author reports on a 56-year-old woman who was moribund when seen in consultation. Her temperature was 105 F (40.6 C), pulse rate 135, and respirations 35. The mucous membranes of the mouth and throat were covered by a thick, gray membrane. She was unable to give her history. The white blood cell count had been 450 on admission the previous day and was 400 the next morning. All cells were lymphocytes. The sedimentation rate was 123 mm. in one hour. By the morning of the second hospital day she had already received 2,000,000 units of penicillin intravenously and 400,000 units every four hours intramuscularly, as well as 0.5 gm. of streptomycin twice daily, without apparent effect. Because death seemed imminent and no evaluation could be made as to the status of the adrenals, treatment with both corticotropin and cortisone was started. Corticotropin was given in 25-mg. doses every six hours, and cortisone was given intramuscularly, 300 mg. the first day, 200 mg. per day on the second and third days, and 100 mg. daily thereafter. The dose of both corticotropin and cortisone and also that of penicillin and streptomycin was gradually reduced as the dramatic response of the patient warranted. A marked leukemoid reaction in the bone marrow abated with cessation of the steroid therapy. The immediate response in this patient, confirming other reports in the literature, indicates that corticotropin and/or cortisone with antibiotics should be the treatment of choice in severe agranulocytosis.

Studies on the Control of Hypertension: VII. Effects of Ganglionic Blockade Combined with Hydralazine on the Malignant Stage Complicated by Renal Azotemia. H. M. Perry Jr. and H. A. Schroeder. Circulation 14:105-114 (July) 1956 [New York].

Of the patients admitted to Barnes Hospital, St. Louis, between Aug. 1, 1951, and Aug. 1, 1955, with malignant stages of hypertension and renal azotemia, 82 were treated with a combination of ganglionic blocking agents and hydralazine. In this paper, malignant hypertension implies a clinical diagnosis that makes no prediction about the presence of renal arteriolar necrosis. The term malignant hypertension (as employed here) designates a condition characterized by a persistent elevation of diastolic pressure at rest above 120 mm. Hg; hemorrhagic and exudative retinitis with papilledema; proteinuria, and diminished renal function. All the patients had nitrogen retention that failed to disappear after the correction of heart failure. On admission to the hospital, 8 patients were believed to have hypertensive encephalopathy, manifested by confusion or coma; 7 others had pulmonary edema; and 12 more showed significant signs of left ventricular failure. Five patients had histories suggesting that they had suffered apoplectic strokes, and two had electrocardiographic evidence of previous myocardial infarction; 4 had been subjected to surgical sympathectomies.

Sixty-six of the 82 patients continued the treatment. Twenty-eight of these are alive after an average of 21.4 months, and 38 died after an average of 4.7 months. The 66 were arbitrarily divided on the basis of the degree of nitrogen retention before treatment. Twenty-seven of the 46 patients with less than 61 mg. of nonprotein nitrogen per 100 ml. of plasma are being successfully maintained on therapy, whereas only 1 of 20 patients with more marked azotemia has survived. The 16 patients who discontinued the treatment had less than 61 mg. of nonprotein nitrogen per 100 ml. of plasma before treatment. Four were lost to follow-up immediately after discharge from the hospital and are presumably dead. The other 12 are known to have died within a month of discontinuing antihypertensive drugs. Eight of these died with uremia less than 60 days after starting therapy. The remaining four died from 3 to 15 months after treatment was begun, the first after an episode of hypertensive encephalopathy, the second and third after cerebral hemorrhage, and the last as a result of progressive malignant hypertension when hydralazine was withdrawn because of disseminated lupus erythematosus.

Some of these patients, all of whom were in the final stage of a rapidly progressive fatal disease, lived and worked for years with the aid of the antihypertensive regimen. Their tension was maintained near normal and their cardiac function improved, but renal function did not change. Autopsy was performed on 32 of the patients. Heart failure had occurred in 15 and renal failure in 21. The major postmortem diagnoses were fibrinous pneumonitis in 18, renal arteriolar necrosis in 13, pyelonephritis in 4, and myocardial infarction and cerebral vascular accident in one each; however, in the 11 cooperative patients with initially mild azotemia, uremia occurred only once and fibrinous pneumonitis eight times.

Blood Pressure Studies Among American and Foreign-Born Students. N. Szent-Györgyi. Circulation 14:17-24 (July) 1956 [New York].

The author studied the blood pressure of 3,508 students at the University of Chicago. Those with evidence of heart disease, diabetes, hyperthyroidism, or hormonal dysfunction were excluded. Patients with hypertension who also had albuminuria were likewise excluded. The incidence of hypertension was ascertained with regard to the sex, the geographic location of the birthplace, the duration of residence in America, and the race of the student. The incidence of hypertension was 6.9% among the white Americans and Europeans. Eight per cent of the white American men and 3.2% of the women were hypertensive. The rates were 6.9% for the European men and 6.6% for the European women, but only 3.2% for the non-European foreign-born white men and zero for the women. The incidence of hypertension among American men was significantly higher than among foreign-born men. There was no significant difference in the incidence of hypertension between American and foreign-born women. There was no difference in the incidence of hypertension between American and European-born white students. However, the percentage among foreign-born non-European white men was less than half that of the American and European white men. American-born and African-born Negro men were represented with rates of 15.6% and 14.2% respectively. There was a higher incidence of hypertension in American Negro men than in any other group examined, topping that of the next highest group, the American white men, by a factor of 2.

The incidence of hypertension among American-born Oriental men was six times higher than among Asian-born Orientals but still lower than among American or European-born white men. Only about a fifth of the foreign-born students had lived in the United States more than 10 years prior to the examination. The incidence of hypertension in this group was 8.5%, that is, the same as among American-born white men. It appears that if someone lives in the United States long enough—regardless of birthplace or race—he will stand the same chance of becoming hypertensive as if he had been born here.

Attempt at Treatment of External Lymph-Node Tuberculosis with Cortisone. J. Bernard, P. Grenet and others. Sang 27:131-137 (No. 2) 1956 (In French) [Paris, France].

Treatment of lymph-node tuberculosis must be evaluated according to the characteristics of the disease: on one hand, its habitual mildness and frequent spontaneous curability, and on the other its prolonged course and the deforming scars it produces. Treatment must be harmless and rapidly effective (in 2 to 4 weeks) and it must prevent the scars resulting from fistulization. The ineffectiveness of the ordinary drugs used in treating lymph-node tuberculosis and the good results obtained with adrenocortical hormones in exudative tuberculosis and with cortisone pomade in the treatment of tuberculous ulcers of lymphatic origin led to a therapeutic use of cortisone in 30 patients suffering from lymph-node tuberculosis; they ranged in age from 1 to 52 years, and 18 were less than 10 years old. The duration of the symptoms before the hormone treatment was started varied from 15 days to 1 year. Seventeen patients had no treatment before they were given cortisone; 3 had had a surgical intervention followed by a relapse; 10 had been treated with antituberculous drugs, mostly isoniazid and aminosalicylic acid combined. Two of these patients recovered temporarily, but treatment in the other eight was ineffective. Cortisone was given with isoniazid in six cases. Intralymphatic injections of hydrocortisone were used in 18 patients (associated with isoniazid by mouth in 10), and hydrocortisone in local injections with cortisone by mouth was used in 6 cases under cover of isoniazid. The greater efficacy of hydrocortisone led to its use in unifocal cases, while cortisone was given orally in plurifocal cases. Failures included complete lack of response, cases in which the lymph nodes did not regress to less than two-thirds of their initial volume, and cases in which superinfection forced abandonment of the treatment. Results were considered successful when the swollen lymph nodes disappeared completely or left only small fibrous or calcareous residues. Treatment in 23 cases was effective and rapid. The failures were analyzed and found to be due to insufficient dosage, to superinfection, or to relapse, which is a frequent occurrence. Recovery is rapid, occurring usually in from 15 to 20 days. The value of antibiotics is open to question. Surgical treatment necessitates general anesthesia and dissection of a richly vascularized and innervated region, carrying the risk of injury to the nerves, and does not prevent relapse. Cortisone seems to be the best treatment for external lymph-node tuberculosis because of its harmlessness, its rapidity of action, and its esthetic results.

SURGERY

Results of Valvulotomy for Valvular Pulmonary Stenosis with Intact Ventricular Septum: Analysis of 69 Patients. D. M. Hosier, J. L. Pitts and H. B. Taussig. Circulation 14:11-16 (July) 1956 [New York].

Transventricular pulmonary valvulotomy was performed at the Johns Hopkins Hospital on 86 patients with pulmonary valvular stenosis and an intact ventricular septum. There were seven deaths. Sixty-nine patients have been followed for from three months to four years postoperatively. Subjective improvement was observed in all but two of these patients. The comparison of the hemograms and arterial oxygen saturations shows improvement in all patients but one, in whom an associated anomaly of the pulmonary venous return is suspected. The analysis of the postoperative physical findings showed the murmur to be less intense in 24 patients and a systolic thrill to have disappeared in 14 of these patients. In 15 patients, a systolic murmur was heard in the pulmonic area. Engorgement of the liver was not noted in any of the patients, and, in every instance in which pulsations at the liver edge were present before operation, the pulsations ceased almost immediately after it. Studies on the size of the heart showed that, if the heart was not enlarged preoperatively, there was no change in its size, whereas, when the heart was enlarged, several distinct changes were noted. In patients under 2 years of age, there was an actual increase in the size of the heart in the immediate postoperative period. Later examinations, however, showed the heart size to have remained stationary while the chest grew. In patients over 18 years of age, the heart decreased steadily in size during the first few postoperative months. In some of the younger patients, the size of the heart decreased to within normal limits and then grew normally with the growth of the chest; in others, the heart remained the same size while the chest grew; and in still others, only progressive enlargement ceased, and the heart and the chest grew together. Cardiac catheterization showed a correlation between the postoperative pressure and the change in the size of the heart. In those patients in whom the pressure was reduced to below 100 mm. Hg the size of the heart returned to normal. These patients were considered to have obtained an excellent result.

Carcinoma of the Thyroid. N. D. Wilson, D. B. Seabrook and R. B. Stevens. Northwest Med. 55:767-771 (July) 1956 [Seattle].

A study of mortality in 109 cases of carcinoma of the thyroid, in which one-third of the patients died of uncontrolled cancer, indicates that this carcinoma kills when inadequately treated and should be attacked as vigorously as cancer elsewhere in the body. Early definitive treatment is especially important. Categories of the cases were papillary carcinoma (42.2%), adenocarcinoma in an adenoma or malignant adenoma (36.7%), and anaplastic carcinoma (21.1%). In fatal cases of papillary carcinoma, death is caused by the local spread of the uncontrolled primary tumor in almost every case. The primary tumor frequently is invasive, although metastatic growths in cervical lymph nodes are not. Local recurrence after removal of involved lymph nodes is not common. Recurrences are to be found in the periphery of the gland dissection field or in lymph nodes left behind at the previous operation. The tumors once described as lateral aberrant thyroid tumors were in fact metastases in the lymph nodes from papillary carcinoma of the thyroid. Malignant adenomas metastasize later than papillary tumors, and the spread is usually distant. Papillary tumors metastasize earlier and to the local nodes So-called "benign metastasizing goiter" is in fact malignant adenoma of low grade. Anaplastic carcinomas, which include all adenocarcinomas not in the first two groups, grow and spread rapidly, metastasize early, are resistant to all forms of treatment, and are frequently fatal. Fifteen per cent of the patients with papillary carcinoma died as a result of cancer. Thus tumor was uncontrolled in 30 per cent in this group, which is supposed to respond best to treatment. Twenty-five per cent of the patients with malignant adenoma died; 30% of the cases were uncontrolled. In the patients with anaplastic carcinoma there was a mortality rate of 82.6% and an uncontrolled rate of 95.6%. Treatment received by the 36 patients of this report who died was in most cases inadequate if judged by current standards of cancer surgery. Only 2 of the 36 had total lobectomy and radical neck dissection. Four others had total lobectomy or thyroidectomy with or without therapy. Nine had no treatment or biopsy only. The remainder had some form of subtotal thyroidectomy, usually with radiation therapy. Median survival times of the patients who died were 48 months for those with papillary tumors, 27 months for adenocarcinoma, and 6 months for anaplastic carcinoma. Radical neck dissection was used in the treatment of two of the longest survivors.

Total lobectomy is recommended for all thyroid adenomas. Carcinoma should be suspected in any nodular goiter. Disadvantages of subtotal resection for thyroid nodules include the dangers of leaving cancer in the residual gland, seeding cancer cells throughout the field, and missing the tumor entirely. With total lobectomy there is improved chance of complete control of the primary tumor. Since a high proportion of the patients who die do so as a result of uncontrolled local disease, every effort must be made to eradicate the disease locally. Radical neck dissection should be carried out in every case of carcinoma of the thyroid when the primary tumor is resectable and no distant metastases can be demonstrated. Regional metastases, found in a high percentage of cases (perhaps 50%), may be present without palpably enlarged lymph nodes. Irradiation is no substitute for surgical excision of the gland.

Radiological Tests to Determine the Use of Surgery in Carcinoma of the Bronchi. L. Caldarola. Minerva chir. 11:406-416 (May 31) 1956 (In Italian) [Turin, Italy].

Expansion of carcinoma of the lung can be more successfully diagnosed and studied if the standard ronetgenological tests are combined with bronchography, stratigraphy, pneumonography, and angiocardiography. The author advises surgery only in case of cancer that lends itself to complete resection, isolated or together with hilar lymph nodes. Patients with infiltration of the mediastinum, pleura, ribs, diaphragm, and pericardium have better results if treated medically. Stratigraphy is particularly useful in the study of carcinoma of the parahilum. The separation of the different planes makes is possible to detect the tumor. Pneumonography helps to establish with certainty the extent of infiltration in the mediastinum. The topography and benign or malignant nature of the affection are best determined with angiopneumonography. To choose one method exclusively or to give it priority is not advisable, since each method complements the others. Bronchography, however, has mainly a local diagnostic value. The other three methods are of particular help in determining the extent of infiltration in the mediastinum.

New Surgical Approach to the Relief of Angina Pectoris. L. T. Palumbo. J. Iowa M. Soc. 46:343-349 (July) 1956 [Des Moines, Iowa].

Palumbo describes an anterior, transthoracic, transpleural approach to the upper dorsal sympathetics, and shows that it is a safer and much simpler procedure than others that have commonly been used in the past. It makes possible a complete and permanent sympathetic denervation of the heart, coronary vessels, head, neck, and upper extremities. It carries lower morbidity and mortality rates than do other methods of sympathectomy. With the use of this technique, the patient can be given greater assurance that complete or almost complete relief of angina pectoris will follow, and his rehabilitation will be more rapid than with other methods of sympathectomy. In many patients cardiac function will improve, and some of them will be able to return to the occupations they had before they were incapacitated by the anginal attacks.

Studies carried out during the development of this new technique revealed a new concept concerning the pupillociliary sympathetic pathways. Even though the first dorsal ganglion (lower third of the stellate ganglion) is removed, a Horner's syndrome does not occur. It is assumed, therefore, that the pupillociliary pathways do not pass via the first ramus communicans to the first dorsal ganglion but are, apparently, conveyed by a separate paravertebral pathway to the upper portion of the stellate ganglion.

Kartagener's Syndrome: Report of a Case Treated by Middle Lobe Lobectomy. T. C. Moore and R. A. Silver. Am. Surgeon 22:595-597 (June) 1956 [Baltimore].

The 20-year-old man whose history is presented had the triad of bronchiectasis, situs inversus, and sinusitis. The bronchiectasis involved the middle lobe in the left hemithorax. The patient had suffered from a severe cough and almost continuous respiratory infection. Middle-lobe resection was carried out. The patient tolerated the operation well. Chest suction was maintained for 48 hours following the operation. The remaining lobes on the left expanded well. The postoperative course was uneventful, and there was considerable improvement, at least during the rather brief period of observation.

The authors point out that the frequent association of situs inversus, bronchiectasis, and sinusitis was first emphasized by Kartagener in 1933. Up to the present time, 105 cases of Kartagener's syndrome have been reported. Pulmonary resection was carried out in only 9 of the 105 patients. A number of these cases were discovered on autopsy. Some were studied prior to the current acceptance of resection for bronchiectasis. Others were too advanced to benefit from resection or too early or minimal to justify this procedure. Middle-lobe resection has been carried out in only one other patient with Kartagener's syndrome.

Mediastinal Emphysema and Bilateral Pneumothorax Following Surgery of the Neck. L. C. Rollins and D. H. Poer. Am. Surgeon 22:567-572 (June) 1956 [Baltimore].

Mediastinal emphysema and pneumothorax constitutes a severe although uncommon complication of any surgery of the neck involving incision into the pretracheal or middle layer of the deep cervical fascia. The authors present the history of a woman in whom emphysema and pneumothorax developed after an operation for an esophageal diverticulum of the pulsion type. This complication has been reported after tracheotomy, radical neck dissection, block or ectomy of the stellate ganglion, esophageal surgery, tonsillectomy, and even after anesthetization alone. The surgeon may cause this complication if the pleura is inadvertently incised beneath Sibson's aponeurosis at the cupola of the lung, and the anesthesiologist may be at fault if hyperinflation of the pulmonary circuit has occurred. In many instances the air enters the mediastinum and pleural space directly by way of fascial planes, as has been shown by autopsy findings. The knowledge of the possible development of this clinical entity and the ability to recognize its presence are essential to diagnosis. The most common early findings are subcutaneous emphysema, pain in the chest, variation from the normal respiratory pattern, evidence of circulatory failure, and auscultatory findings. Roentgen examination of the chest corroborates the diagnosis and may be used to follow the progress of the complication.

The importance of prompt and adequate therapy cannot be overemphasized. If the patient has not yet reacted after anesthesia, an airway must be induced. Oxygen should be given either nasally or by tent, but not by a positive pressure mask. Analgesics and meperidine (Demerol) may be used to alleviate anxiety as well as for shock and pain, but morphine should not be used, because it depresses respiration. Close observation is mandatory, because the development of tension pneumothorax merits immediate needle aspiration and/or closed thoracotomy drainage of the third or fourth intercostal space. If there is little change in the vital signs and if the status of the patient is reasonably satisfactory, it is justifiable to wait for roentgenologic confirmation. Lateral views are valuable in demonstrating the mediastinal and subcutaneous presence of air. Unless this serious complication is recognized and treated, the mortality is extremely high.

Cortisone in the Post-Operative Management of Patients with Advanced Pulmonary Tuberculosis. J. R. Edge. Tubercle 37:166-171 (June) 1956 [London, England].

Five patients, recognized to be very poor surgical risks, were submitted to resection for advanced pulmonary tuberculosis. Each became critically ill in the days following operation, with symptoms of exhaustion and peripheral circulatory failure. After failure to respond to the usual measures, immediate and very striking improvement followed the exhibition of cortisone, which is considered to have been life-saving. One of the patients later died, apparently from pulmonary embolism, whilst the remaining four continue to do well. In no instance has there been evidence of any deleterious effect on the residual tuberculous disease. Two hypotheses may be advanced to account for the action of cortisone in these patients: the facilitation of the effect of the antibacterial drugs, as demonstrated by Houghton; and the relief of nonspecific stress in the presence of presumed adrenal exhaustion by replacement of an active steroid hormone. In view of the very rapid response, the latter action may be the more important; but it has not so far been possible to obtain laboratory evidence in support of this theory. Studies of adrenocortical function before and for several days after operation will be of great interest. Meanwhile, the empirical use of cortisone in the type of case described appears to merit further trial.

The Prognosis in Dissecting Aneurysms of the Aorta: Therapeutic Suggestion. D. J. Freeman. Wisconsin M. J. 55: 709-721 (July) 1956 [Madison, Wis.].

It was the purpose of the studies described to determine the factor or factors influencing the prognosis of dissecting aneurysm of the aorta. The material consisted of 17 patients studied at the Cincinnati General Hospital and 161 cases selected from among 400 described in the literature. The most important single factor seemed to be the spontaneous reentry of the dissected channel into the true aortic lumen at a lower level. Spontaneous reentry of the dissected channel at its distal extent is nature's best method of healing dissecting aneurysm of the aorta. If surgery is contemplated, an attempt should be made to secure reentry at the lowest extent of the dissection.

The author lists the important factors in the management of dissecting aneurysm. Early diagnosis is vital and angiocardiography and retrograde aortography may prove to be helpful in the diagnosis. An effort should be made to estimate the extent of the dissection. Sedatives, analgesics and suitable antihypertensive drugs should be given immediately. Surgical production of reentry of the false dissected channel into the true aortic lumen at the lowest possible level should be attempted without delay, because the mean survival time is only about three or four days, and some patients fail to survive even 48 hours. If surgery is carried out, anticoagulant therapy should be instituted on the second postoperative day.

with adrenocortical hormones in exudative tuberculosis and with cortisone pomade in the treatment of tuberculous ulcers of lymphatic origin led to a therapeutic use of cortisone in 30 patients suffering from lymph-node tuberculosis; they ranged in age from 1 to 52 years, and 18 were less than 10 years old. The duration of the symptoms before the hormone treatment was started varied from 15 days to 1 year. Seventeen patients had no treatment before they were given cortisone; 3 had had a surgical intervention followed by a relapse; 10 had been treated with antituberculous drugs, mostly isoniazid and aminosalicylic acid combined. Two of these patients recovered temporarily, but treatment in the other eight was ineffective. Cortisone was given with isoniazid in six cases. Intralymphatic injections of hydrocortisone were used in 18 patients (associated with isoniazid by mouth in 10), and hydrocortisone in local injections with cortisone by mouth was used in 6 cases under cover of isoniazid. The greater efficacy of hydrocortisone led to its use in unifocal cases, while cortisone was given orally in plurifocal cases. Failures included complete lack of response, cases in which the lymph nodes did not regress to less than two-thirds of their initial volume, and cases in which superinfection forced abandonment of the treatment. Results were considered successful when the swollen lymph nodes disappeared completely or left only small fibrous or calcareous residues. Treatment in 23 cases was effective and rapid. The failures were analyzed and found to be due to insufficient dosage, to superinfection, or to relapse, which is a frequent occurrence. Recovery is rapid, occurring usually in from 15 to 20 days. The value of antibiotics is open to question. Surgical treatment necessitates general anesthesia and dissection of a richly vascularized and innervated region, carrying the risk of injury to the nerves, and does not prevent relapse. Cortisone seems to be the best treatment for external lymph-node tuberculosis because of its harmlessness, its rapidity of action, and its esthetic results.

SURGERY

Results of Valvulotomy for Valvular Pulmonary Stenosis with Intact Ventricular Septum: Analysis of 69 Patients. D. M. Hosier, J. L. Pitts and H. B. Taussig. Circulation 14:11-16 (July) 1956 [New York].

Transventricular pulmonary valvulotomy was performed at the Johns Hopkins Hospital on 86 patients with pulmonary valvular stenosis and an intact ventricular septum. There were seven deaths. Sixty-nine patients have been followed for from three months to four years postoperatively. Subjective improvement was observed in all but two of these patients. The comparison of the hemograms and arterial oxygen saturations shows improvement in all patients but one, in whom an associated anomaly of the pulmonary venous return is suspected. The analysis of the postoperative physical findings showed the murmur to be less intense in 24 patients and a systolic thrill to have disappeared in 14 of these patients. In 15 patients, a systolic murmur was heard in the pulmonic area. Engorgement of the liver was not noted in any of the patients, and, in every instance in which pulsations at the liver edge were present before operation, the pulsations ceased almost immediately after it. Studies on the size of the heart showed that, if the heart was not enlarged preoperatively, there was no change in its size, whereas, when the heart was enlarged, several distinct changes were noted. In patients under 2 years of age, there was an actual increase in the size of the heart in the immediate postoperative period. Later examinations, however, showed the heart size to have remained stationary while the chest grew. In patients over 18 years of age, the heart decreased steadily in size during the first few postoperative months. In some of the younger patients, the size of the heart decreased to within normal limits and then grew normally with the growth of the chest; in others, the heart remained the same size while the chest grew; and in still others, only progressive enlargement ceased, and the heart and the chest grew together. Cardiac catheterization showed a correlation between the postoperative pressure and the change in the size of the heart. In those patients in whom the pressure was reduced to below 100 mm. Hg the size of the heart returned to normal. These patients were considered to have obtained an excellent result.

Carcinoma of the Thyroid. N. D. Wilson, D. B. Seabrook and R. B. Stevens. Northwest Med. 55:767-771 (July) 1956 [Seattle]

A study of mortality in 109 cases of carcinoma of the thyroid in which one-third of the patients died of uncontrolled cancer, indicates that this carcinoma kills when inadequately treated and should be attacked as vigorously as cancer elsewhere in the body. Early definitive treatment is especially important. Categories of the cases were papillary carcinoma (42.2%), adenocarcinoma in an adenoma or malignant adenoma (36.7%), and anaplastic carcinoma (21.1%). In fatal cases of papillary carcinoma, death is caused by the local spread of the uncontrolled primary tumor in almost every case. The primary tumor frequently is invasive, although metastatic growths in cervical lymph nodes are not. Local recurrence after removal of involved lymph nodes is not common. Recurrences are to be found in the periphery of the gland dissection field or in lymph nodes left behind at the previous operation. The tumors once described as lateral aberrant thyroid tumors were in fact metastases in the lymph nodes from papillary carcinoma of the thyroid. Malignant adenomas metastasize later than papillary tumors, and the spread is usually distant. Papillary tumors metastasize earlier and to the local nodes So-called "benign metastasizing goiter" is in fact malignant adenoma of low grade. Anaplastic carcinomas, which include all adenocarcinomas not in the first two groups, grow and spread rapidly, metastasize early, are resistant to all forms of treatment, and are frequently fatal. Fifteen per cent of the patients with papillary carcinoma died as a result of cancer. Thus tumor was uncontrolled in 30 per cent in this group, which is supposed to respond best to treatment. Twenty-five per cent of the patients with malignant adenoma died; 30% of the cases were uncontrolled. In the patients with anaplastic carcinoma there was a mortality rate of 82.6% and an uncontrolled rate of 95.6%. Treatment received by the 36 patients of this report who died was in most cases inadequate if judged by current standards of cancer surgery. Only 2 of the 36 had total lobectomy and radical neck dissection. Four others had total lobectomy or thyroidectomy with or without therapy. Nine had no treatment or biopsy only. The remainder had some form of subtotal thyroidectomy, usually with radiation therapy. Median survival times of the patients who died were 48 months for those with papillary tumors, 27 months for adenocarcinoma, and 6 months for anaplastic carcinoma. Radical neck dissection was used in the treatment of two of the longest survivors.

Total lobectomy is recommended for all thyroid adenomas. Carcinoma should be suspected in any nodular goiter. Disadvantages of subtotal resection for thyroid nodules include the dangers of leaving cancer in the residual gland, seeding cancer cells throughout the field, and missing the tumor entirely. With total lobectomy there is improved chance of complete control of the primary tumor. Since a high proportion of the patients who die do so as a result of uncontrolled local disease, every effort must be made to eradicate the disease locally. Radical neck dissection should be carried out in every case of carcinoma of the thyroid when the primary tumor is resectable and no distant metastases can be demonstrated. Regional metastases, found in a high percentage of cases (perhaps 50%), may be present without palpably enlarged lymph nodes. Irradiation is no substitute for surgical excision of the gland.

Radiological Tests to Determine the Use of Surgery in Carcinoma of the Bronchi. L. Caldarola. Minerva chir. 11:406-41 (May 31) 1956 (In Italian) [Turin, Italy].

Expansion of carcinoma of the lung can be more successfully diagnosed and studied if the standard ronetgenological tests are combined with bronchography, stratigraphy, pneumonography, and angiocardiography. The author advises surgery only in case of cancer that lends itself to complete resection, isolated or together with hilar lymph nodes. Patients with infiltration of the mediastinum, pleura, ribs, diaphragm, and pericardium have better results if treated medically. Stratigraphy is particularly useful in the study of carcinoma of the parahilum. The separation of the different planes makes is possible to detect the tumor Pneumonography helps to establish with certainty the extent of infiltration in the mediastinum. The topography and benign or malignant nature of the affection are best determined with the injury resulted from a fall and in one from a torsion strain The fractures were treated by means of a walking-cast Functional results were good The man who sustained bilateral talus fractures had fallen from a height of 21 ft There was a transverse fracture of the talus of the left foot, with mild dislocation of the anterior part of the foot, and a fracture of the medial tibial malleolus The right foot showed a fracture of the lateral process of the talus and a fracture of the medial tibial malleolus The results of conservative treatment were such that the man was able to resume heavy labor without further symptoms A fall from a considerable height caused transverse fracture of the talus with dislocation of the anterior part of the foot in two other patients A trimalleolar ankle fracture was associated in one The fractures were immobilized for three months following reposition, after which there was a satisfactory functional result

Three patients had a fracture on the medial side of the trochlea tali in addition to their ankle fracture An 11-year old boy sustained an incomplete transverse fracture of the talus combined with a fracture of the medial tibial malleolus Treatment by means of a walking-cast led to complete recovery Two multiple fractures of the talus occurred as a result of severe incarceration of the foot Reposition was insufficient in both cases The talus fragment, which showed dorsal displacement, gave rise to a bone block causing impairment of the dorsal flexion It is hoped that an arthrotomy with extirpation of the prominences will improve the function Avascular necrosis was seen in four cases of old fractures of the talus The corpus tali was sclerotic and flattened, and there was arthritis deformans of the adjacent joints Two patients were treated by arthrodesis for pain and varus position of the foot In a 67-year-old woman the talus had been extirpated elsewhere because of complicated dislocation Tibiotarsal arthrodesis was advised because of pain Dislocation of the talonavicular joint was observed in a woman seen in the outpatient clinic She had had an accident three months previously Treatment was not prescribed because the symptoms were extremely mild

Reconstruction of Thumb by Toe Transfer. B S Freeman Plast & Reconstruct Surg 17:393 398 (May) 1956 [Baltimore]

Freeman reports on a 20-month-old boy who had had his right thumb ripped off by a huge dog The residual stump showed an avulsion of skin and subcutaneous tissue at the metacarpophalangeal joint with the exposed base of the proximal phalanx the distal phalanx and two thirds of the proximal phalanx were gone A dorsal, bipedicle flap was used to close over the bare bone, and the donor site was covered with a thick split graft The stump healed with a durable covering but was obviously too short to be of much functional use A toe-to-thumb transplant was deemed advisable, but, instead of using the relatively stiff big toe, it was decided to use the second toe, which is of much less importance in locomotion than is the big toe Three months after injury, the stump of the thumb was dissected free to expose the remnant of the proximal phalanx, the extensor tendon, and, under considerable tension the tendon of the flexor pollicis longus A transverse dorsal incision over the metatarsophalangeal joint of the right second toe was carried to the midlateral lines, exposing the joint and the flexor and extensor tendons The tendons were cut 0 5 in proximally to the incision and the digit disarticulated The base of the proximal phalanx was sectioned, a mortise cut to correspond with a similar section in the remnant of the thumb, and, after the hand was brought down no 32 wire used for an interosseous suture The flexor and extensor tendons were coapted with no 5-0 white silk and the dorsal skin closed with one row of sutures While the hand and foot were held in position with the fingers wrapped about the sole, a right-arm right-foot skin-tight plaster cast was applied

On the eighth postoperative day the sutures were removed, and it was noted that the hand no longer lay across the instep but had migrated medially. Ten days after that the median plantar pedicle was sectioned to the midline of the plantar surface and the vessels ligated. As the undersurface of the stump had become attached, it was with difficulty that this was raised sufficiently to suture it to the plantar edge of the toe with three mattress sutures The tension due to the retraction of the hand was relieved by shifting the dressing, and the foot defect was closed Later the child fell on the hand and sustained a fracture This was reduced and a cast was applied Three weeks later x-ray examination showed excellent bone formation but an increase in the lateral angulation of the distal thumb portion Obviously the flexor tenorrhaphy had separated and the unopposed extensor mechanism had caused a posterior deformity after the fracture It was difficult to maintain the splint, and it was discarded Although the patient used his hand constantly, the 20 degree posterior deformity was annoying and was corrected by a simple osteotomy and splinting with a plaster cast Three years later the transplanted thumb showed practically normal function and sensation as well as evidence of growth For a child reconstruction of a thumb by toe transfer would seem to be preferable to any other method

Familial Polyposis of the Colon R P McBurney and R L Sanders Am Surgeon 22 583-594 (June) 1956 [Baltimore]

The authors report on 10 patients with polyposis of the colon all of whom had a family history of colon disease, mostly of colonic polyposis and/or cancer of the colon Familial polyposis of the colon is inherited as a Mendelian dominant or recessive It is transmitted by both sexes, and usually appears at puberty or in the second or third decades of life Carcinoma develops in a high percentage of the patients Colonic polyps are premalignant lesions and their presence constitutes a threat to the life of the patient The treatment of the isolated polyp or even a few polyps is not too difficult, familial polyposis, however, wherein the colon contains literally thousands of the growths, frequently presents a serious surgical problem While it is recognized that polyposis calls for surgical intervention, there is some disagreement as to the choice of procedures The advantage of subtotal colectomy with ileosigmoidostomy or ileoproctostomy lies in the fact that sphincteric control is retained the number of stools is low, and little or no nutritional problem arises following operation In addition, the remaining segment of the colon can be observed through the sigmoidc [illegible] guration of residual or subsequent polyps [illegible] tissue is left in the body, however, when this procedure is used, and many patients will not cooperate by having proper follow-up proctoscopic examinations

Peutz described a syndrome of melanosis of the oral mucous membranes with polyposis of the intestines, and Jeghers and associates observed melanosis of both the oral mucosa and the digits in association with intestinal polyposis None of the patients presented here had polyps in regions other than the colon, and none had pigmented areas in the buccal mucous membranes or the digits Nor did any of the group have multiple sebaceous cysts in combination with colonic polyps, an association recently described by Oldfield Multiple polyps and pseudopolyps, found after long-standing inflammation of the colon, are similar in some respects to familial polyposis, but are, in reality, a different disease In both conditions there appears to be a propensity to malignant degeneration An occasional patient with polyposis will meet disaster from hemorrhage, perforation, or intussusception the principal danger, however, is the development of a carcinoma

NEUROLOGY & PSYCHIATRY

Indications for and Results of Surgical Treatment in Temporal Epilepsy. J Guillaume and G Mazars Semaine hop Paris 32 2013-2018 (June 10) 1956 (In French) [Paris, France]

Analysis of the results obtained in 110 patients with temporal epilepsy operated on during an eight-year period shows that more than three fourths were benefited and that about one-half were significantly improved The procedure, which is benign, should not be regarded as a last resort for severely ill patients whose epilepsy is uncontrolled or poorly controlled by medication and who are burdened by an intellectual deficit or personality disturbances The most significant material and social benefits were obtained in patients with a high intellectual level, some of whom had only a few seizures a month, thanks to careful medical control Few as the seizures were, however, they were sufficient to jeopardize a lucrative career. Surgical treatment, therefore, may legitimately be considered for a patient whose inability to lead a normal life interferes with his scholastic or professional career, even though the attacks are infrequent and the disease of long standing. The "temporal" localization of the epilepsy, however, must be well established before the operation is undertaken. No justification can be found for an intervention in patients with long-standing epilepsy in whom the attacks are infrequent and sufficiently controlled by medication not to interfere with a normal life. The operative indications in patients with diffuse or extensive lesions in whom temporal crises are associated with an intellectual deficit or mental retardation and personality disturbances are less clearly defined. Both the epilepsy and the associated defects will be greatly helped by operation in some of these patients; in others, the patient's general status may remain more or less unchanged while the epilepsy alone is relieved. The percentage of improvements and cures obtained in these patients will not be so high as it is when epilepsy alone is present, nevertheless, operation is indicated in many of these cases because it may transform the existence of patients who would otherwise have to undergo long periods of hospitalization.

Social and economic factors should also be taken into consideration, thus the operative indications should be broader for patients whose livelihood depends on their work than for those whose financial position is assured. Special problems arise in connection with epileptic attacks of comparatively recent appearance, especially in patients between the ages of 15 and 40. Neither the absence of associated neurological signs nor the lack of signs of intracranial hypertension can exclude the possibility of neoplasia in such patients, yet they should not be routinely subjected to operation. They should be kept under observation, and intensive anticomitial treatment should be postponed until the possibility of a neoplasm can reasonably be excluded because of the absence of change in the electroencephalographic tracings over an adequate period of time.

New Predisposing Factor in Poliomyelitis: A Previous Neurological Disease. E. Rodriguez-Vigil Lorenzo. Rev. españ pediat. 22:229-240 (March-April) 1956 (In Spanish) [Zaragoza, Spain].

According to the literature, a neurological disease in a child is a predisposing factor to the development of poliomyelitis The author observed four infants and two young children who developed poliomyelitis after a previous neurological disease, consisting of a chronic encephalopathy in three cases, encephalopathy and purulent meningitis in one, and tuberculous meningitis in two. The author believes that the neurological disease causes a weakness of the central nervous system that favors the development of poliomyelitis. For prevention, the antipoliomyelitis vaccine should be given by preference to infants and children who have suffered a neurological disease. In children who have had a neurological disease, the central nervous system is vulnerable to the effect of bacterial and viral agents. It is advisable to give the antipoliomyelitis vaccine as soon as possible after the occurrence of a neurological disease. Poliomyelitis in the cases reported by the author and those cited in the literature occurred at a period that varied from several days to a few months after the neurological disease.

Reserpine and Chlorpromazine in Psychiatry. A. T. Knutsen. Tidsskr. norske lægefor. 76:368-371 (June 1) 1956 (In Norwegian) [Oslo, Norway].

In Eg Hospital 154 patients were treated with chlorpromazine and/or reserpine from February, 1955, to February, 1956. The results are evaluated in the 143 patients observed for from 1 to 12 months. The material includes 94 cases of schizophrenia, 24 of manic-depressive psychosis, and 18 of constitutional psychosis. Most of the patients had a long history of illness, in some cases 20 years or more, and had shown little or no response to other treatment. Thirteen are now without psychotic signs and able to work, 28 are considerably improved, partly able to work and more social, 80 are more easily cared for and in some of these, treated for a short time, there is hope for further improvement, while in 21 the treatment seems to have been without effect, although here also improvement might still be expected in some cases. There was no aggravation ascribable to the treatment. Change to reserpine or a combination of the two agents after start of treatment with chlorpromazine was mostly because of the greater cost of chlorpromazine. To date, the side-effects of chlorpromazine have been few and those of reserpine fewer. Phenergan is a good antidote for the allergic conditions that may be looked for with chlorpromazine and together with chlorpromazine has a good hypnotic effect; it has therefore almost as a routine measure been given to patients who received larger doses of chlorpromazine. The chlorpromazine dosage was from 75 to 600 mg. daily, apportioned in two or three doses and given either by deep intramuscular injection or by mouth. The reserpine dosage was from 0.50 to 4 mg. daily, by mouth, and apportioned in two or three doses. Effective dosage should be reached as soon as possible.

Tuberculous Meningitis: A Study of Cases Treated at Wellington Hospital During the Period 1950-55. I. A. M. Prior. New Zealand M. J. 55:117-124 (April) 1956 [Wellington, New Zealand].

Twenty-seven patients with tuberculous meningitis were treated in a hospital in Wellington, New Zealand, during the years from 1950 to 1955. Thirteen were treated from 1950 to 1952 and 14 from 1953 to 1955. The ages of the patients ranged from 14 months to 50 years. Twelve of the 13 patients treated during the first three-year period (1950 to 1952) died, and the one survivor was the only patient of that group who had received isoniazid. In the second three-year period (1953 to 1955), all but two of the patients received isoniazid, and 11 of the 14 survived. The much more favorable results obtained in the second group seem to be due to the treatment with isoniazid. One of the three who died had not received isoniazid; an infant died of miliary tuberculosis on the day after admission; and the third patient died of a relapse 10 weeks after discharge, despite resumption of treatment. Neurological complications developed in four of the six patients who were treated with systemic and intrathecal administration of streptomycin together with isoniazid. Evidence favors treatment without the intrathecal administration of streptomycin. The early subjective improvement and the cerebrospinal-fluid findings in four patients treated with cortisone or corticotropin confirm the advantages of this treatment, although it did not prevent the development of spinal block in two of these patients. In one of the two patients the block lasted 10 weeks, while in the other it was of shorter duration. Neither patient showed any evidence of spinal-cord involvement.

PEDIATRICS

Delayed Effects Occurring Within the First Decade After Exposure of Young Individuals to the Hiroshima Atomic Bom R. W. Miller. Pediatrics 18:1-18 (July) 1956 [Springfield, Ill

The author reports the findings of the Atomic Bomb Casual Commission (ABCC) on examination of 4,407 patients in 19 at the Hiroshima ABCC Pediatrics Clinic. The youngest were i utero and the oldest were 10 years of age at the time of t detonation of the bomb in 1945. Those who were within 1,80 m. of the hypocenter (the point directly under the atomic bom when it exploded) are believed to have been subjected to som ionizing radiation if they were not by coincidence shielde Most of those beyond this distance probably received an incon sequential amount. Thirty-three children who were expose while in utero to the explosion have head circumferences 2 more standard deviations below normal. Twenty-four of thes were between the 7th and 15th week of gestational age at th time of detonation of the bomb. The incidence and the severity of microcephaly increases as the distance from the hypocente decreases. Mental retardation occurred in 15 of the 33 patients The incidence of this defect was also related to the distance from the hypocenter and the gestational age. No other embryologic effects of exposure to the atomic bomb have been detected to date. In the six years ending in December, 1954, 19 persons who were within 2,100 m. of the hypocenter developed leukemi before attaining the age of 19 years. The annual incidence of this disease among those who were within 1,500 m. and who were younger than 10 years of age at the time of exposure is

1:1,000. There are no cataracts that impair vision among the present pediatric group. An increased incidence of a mild visual disability, the cause of which is thus far indefinite, has been found among those now 16 through 19 years of age who were within 1,800 m. of the bomb center. The incidence of chronic otitis media is the same for the group exposed at 1,500 m. and under and the group exposed at 1,501-1,800 m., as are the means of the hematological values for the patients with this ailment. There is no increase in the tumor incidence in the exposed children as compared with the nonexposed. The impression is that among the survivors the fear of late effects may be common and potentially disabling, although there are no data to prove it. In 1954, doctors examined 2,771 people 19 years of age and younger who were within 3,000 m. of the hypocenter at the time of detonation of the bomb. Twenty-four of these had sequelae of the blast or of thermal effects of the bomb other than well-healed scars. No other abnormalities related to exposure have been identified.

Considerations on Anoxia Neonatorum. G. Murano. Pediatria 64: 161-187 (April) 1956 (In Italian) [Naples, Italy].

The author studied the intrinsic and extrinsic causes of anoxia neonatorum in the forms of anoxic anoxia and anoxia due to venous congestion. Complications arising during intrauterine life or during delivery are extrinsic causes. Nervous, pulmonary, hemochemical, and vascular changes are intrinsic causes. The records of 300 infants showed that anoxia occured in 90% of the prematurely born babies. It was severe in 60% of the cases. It was almost always due to intrinsic causes. All premature babies born after at least 6 months' gestation had some form of anoxia. The high concentration of fetal hemoglobin and the lower concentration of carbonic anhydrase must be regarded as symptoms of premature birth. They do not contribute, at least directly, to the anoxic conditions. Anoxia is the cause of death in many more cases than those in which it is registered. In 200 of 325 deaths, the records of which were examined, the author found that anoxia was also present in those babies whose death had been imputed to hemorrhage or sepsis. Anoxia causes neuropsychic disturbances that appear later in the life of the child. The electroencephalographic patterns of 10 such patients are reported to show that prophylaxis of anoxia neonatorum is also necessary from a social point of view.

DERMATOLOGY

The Treatment of Vitiligo with 8-Methoxypsoralen. J. A. Elliott Jr. South. M. J. 49:691-697 (July) 1956 [Birmingham, Ala.].

The Arabs have used a powder made from the fruit of the plant Ammi majus Linn. for the treatment of vitiligo for hundreds of years. Three psoralen derivatives—8-methoxypsoralen, 5-methoxypsoralen, and 8-isoamyleneoxypsoralen—have been isolated from the Ammi majus Linn. fruit; and these compounds have been used orally and locally, separately and in various combinations in the treatment of vitiligo since 1947. This report describes observations on 22 patients who had had vitiligo for from one month to 25 years. Half of the patients had had their depigmented lesions for more than six years. Their ages ranged from 8 to 55 years. Five of the patients were treated for four months in 1954 and for four months again in 1955. The remaining 17 patients were treated over a period varying from 2 to 4 months in 1955 only. Treatment during the summer of 1954 consisted of (1) oral administration of 10 mg. of 8-methoxypsoralen three times a day after meals; (2) exposure of the depigmented areas to sunshine at noon each day, increasing the time of exposure as tolerated; and (3) avoidance of foods with a high vitamin C content. Laboratory studies during this period included urinalysis, blood counts, cephalin-cholesterol flocculation tests, and the determination of urinary porphyrins and of the prothrombin time. During the summer of 1955, 20 mg. of 8-methoxypsoralen was given once a day two hours before exposure to sunshine; otherwise, the treatment was the same as during the previous summer. Either cephalin-cholesterol flocculation tests or serum Bromsulphalein tests were made.

Eighteen patients showed significant degrees of repigmentation. The amount of repigmentation seemed to be more dependent on the total time of exposure to sunshine and the location of the lesion than on the age of the patient, the duration of the disease, or the extent of involvement. The dorsum of the hands and feet showed less repigmentation than lesions over fleshy areas such as the face, abdomen, or axillas. Four patients did not show significant repigmentation, evidently because they did not cooperate adequately. Liver function tests in two patients were significantly abnormal after a period of treatment, forbidding further oral administration of 8-methoxypsoralen. Serum Bromsulphalein tests should be made throughout the period of treatment with 8-methoxypsoralen.

OTOLARYNGOLOGY

The Adenoid and its Relation to the Ear. L. W. Alexander. Laryngoscope 66:711-721 (June) 1956 [St. Louis].

Although the adenoid was once thought to be a completely functionless structure, there is now an increasing belief that the growing child requires nasopharyngeal lymphoid tissue for protection against infection. When, however, adenoid tissue has become hypertrophied, it not only cannot fulfill its normal function but also serves as a focus of infection. The presence of diseased adenoids may be followed by snuffling, nasal obstruction, mucopurulent nasal or postnasal catarrh, absence of nasal resonance, laryngeal stridor, suppuration of the accessory nasal sinuses, cervical adenitis, gastrointestinal disturbances, defective growth and backwardness, inability to fix attention, neuroses, and systemic infections. Neglect of diseased adenoids may have an extremely serious effect upon the ear. Deafness that follows obstruction to the Eustachian tube by adenoid tissue may occur by several mechanisms: the membrana tympani may be indrawn or retracted; postnasal catarrh may spread along the Eustachian canal, with resulting acute and chronic otorrhea. The most dangerous variety of diseased adenoid tissue is the soft, diffuse type, which is apt to become inflamed and suppurative and to cause middle-ear disease and eventual auditory impairment.

It may sometimes be difficult to decide whether or not to remove the adenoids, but removal should be carried out without delay (1) if enlarged adenoids are present in association with chronic suppurative otitis media, and (2) if auditory impairment is present in association with even minimum adenoid vegetations. Unless the removal of the adenoids is carried out with careful attention to technical details, portions of the hypertrophied structure will inevitably be left in situ. The author describes the surgical technique, pointing out that inadequate surgical removal is the most important cause of recurrence. If postoperative recurrence of nasopharyngeal lymphoid tissue gives rise to symptoms, secondary surgery is usually preferable to irradition.

THERAPEUTICS

Results of Treatment of Angina Pectoris with Choline Theophyllinate by Double-Blind Method. C. Aravanis and A. A. Luisada. Ann. Int. Med. 44:1111-1122 (June) 1956 [Lancaster, Pa.].

Treatment of angina pectoris is a difficult problem. Nitroglycerine gives rapid temporary relief, but choline theophyllinate has been said to cause a lasting improvement in patients with coronary heart disease and anginal pain, far greater than that obtained with aminophylline and without producing symptoms of intolerance. Clinical investigations were made in 72 ambulatory patients selected at random from the cardiac clinics of Mount Sinai Hospital, Chicago, most of whom were in older age groups. Choline theophyllinate was tried in 42, while 28 received only placebos (sugar pills) of the same weight and color. No suggestive influence was involved in the results, because the double-blind method was used. No sedative effect was observed, and tolerance was good. From the onset of therapy with choline theophyllinate, all other drugs were withdrawn except for nitroglycerin when there was severe pain. Choline theophyllinate was given by mouth in doses of 3 200-mg. tablets daily. A remarkable increase in tolerance to free exertion was noted in 30% of the patients after two weeks of choline theophyllinate treatment and in 50% after four weeks of this treatment. The number of steps tolerated without discomfort increased. A decrease was also found in the number of attacks of pain and in their severity. Slight side-effects, consisting of nausea in five patients, dizziness in two, decrease in appetite in one, and a feeling of tremor in one, were noted at first, but these effects disappeared when the dose was temporarily decreased from 3 to 2 tablets a day. Most of the patients treated with the placebo showed no improvement, although a few (less than one-third) had a very slight improvement. Nearly one-third of those given choline theophyllinate, on the other hand, had a definite improvement, and over one-fifth had an excellent improvement. Consideration of the mechanism of the action of the drug leads to the conclusion that the effects it produces are not due to vasodilating action. Three possible effects are discussed: decreased load on the left ventricle, production of enzymes in the myocardium, or inactivation of pressor amines in the heart muscle. The last two would improve the utilization of oxygen by the heart. However, no conclusion has been reached in regard to the action of the drug.

Changing Concepts in the Management of Poisonous Animal Injuries: A Plea for Better Management. R. J. Antos. Southwestern Med. 37:418-421 (July) 1956 [El Paso, Texas].

Antos shows that, whereas relief of pain and sedation have been the chief factors in the currently accepted methods of treating bites and stings of poisonous animals, it has become evident in recent years that morphine and meperidine and most likely other narcotics as well are contraindicated, because it has been shown in experiments with animals and in trials with humans that the toxicity of venoms is increased by narcotics. Experimental studies on animals demonstrated also that chilling of the site of inoculation of the venom can slow down the absorption enough to enable the normal detoxification mechanisms of the body to cope more effectively with the poison. Application of a tourniquet, or impeding of the superficial venous and lymphatic return even by simple pressure will slow down absorption of the poison. The combination of the two methods proved still more effective than either method alone. The author is definitely in favor of chilling. At first only ice-water immersion was used. Then pressure or light intermittent application of a tourniquet was added. Gradually, the length of time of tourniquet application was lengthened from five-minute intervals, until now the tourniquets are left on for a half hour or more at a time. For first-aid measures, ethylchloride spray was used until ice could be obtained. Recently Frigiderm, which is dichloro-tetrafluoro-ethane, was found to be superior to ethylchloride. It is nonexplosive and nonflammable, is not an anesthetic, and does not require refrigeration. It can be kept in a first-aid kit.

The treatment of patients who have sustained venomous stings or bites and in whom the origin of the venom is not known is carried out in the following manner: (1) a moderately firm tourniquet is applied at once; (2) the site of the bite is chilled; and (3) calcium salts are injected intravenously. If peripheral pain is relieved immediately by calcium, the chances are strongly in favor of a black widow spider bite. If the calcium does not relieve peripheral pain, then the tourniquet and chilling alone are used; otherwise, further calcium is given as needed. This procedure has been used with favorable results in 27 cases during the past year.

Acute Viral Hepatitis: Aureomycin Treatment. J. Solsona Conillera. Med. clin. 26:343-350 (May) 1956 (In Spanish) [Barcelona, Spain].

Forty patients with acute viral hepatitis were observed. The disease was caused by blood transfusion in five cases. The majority of the patients were young adults. Aureomycin was given in doses of 0.25 gm. every three hours for 10 consecutive days. A man 66 years old died with acute hepatitis that did not respond to treatment. All the remaining patients recovered. The earlier the drug was given the better and more rapid were the results. When the treatment was started within the first five days of the disease, favorable changes in the subjective symptoms and in the general condition of the patient were observed as early as the second day of the treatment in 14 uncomplicated cases. Improvement continued as the treatment progressed; jaundice abated, diuresis increased, hepatomegaly rapidly diminished, and fever and tachycardia, if present, disappeared. The duration of the disease from appearance to disappearance of jaundice in the 14 patients averaged 18 days. In five patients who had the treatment within the first five days of the disease but who had complications as well as in the patients in whom treatment was started after the first five days of the disease, the results were equally favorable, but the symptoms abated slowly and the disease lasted longer than in the patients of the previous group. Among the patients with complications were one who developed a Loeper's syndrome of edema and jaundice and another with jaundice and ascites of long duration that were controlled by aureomycin. The author concludes that aureomycin is valuable in the treatment of acute viral hepatitis. The liver is not injured when the drug is given in the doses and schedules fixed by the author.

Treatment of Amebiasis with Resotren. L. Pfannemueller. Lancet 1:934-935 (June 16) 1956 [London, England].

Resotren is a chemical combination of chloroquine and iodohydroxyquinoline. It is poorly absorbed when taken by mouth and reaches the lower intestine in considerable concentration. About half of it is gradually broken down in the small intestine, releasing chloroquine and iodohydroxyquinoline, which are then absorbed. The remainer passes into the large intestine, where part of it is also split up; thus both chloroquine and iodohydroxyquinoline are brought to the site of infection, where they never are present in such amounts when given separately by mouth. The author presents observations on 42 patients with amebiasis whom he treated while in Iraq. Five of the patients had uncomplicated amebic dysentery, which was acute in three and chronic in the other two; all five were cured. In 31 patients the amebic dysentery was complicated by amebic hepatitis. The liver was palpable and generally enlarged to three fingerbreadths below the costal margin, and pain on pressure was a constant finding. Treatment with resotren produced striking improvement in all patients: the liver returned to its normal size and the symptoms disappeared. In two patients cysts were still present in the stools at the end of treatment; two other patients were not examined at the end of the course. The remaining 27 had no cysts in their stools after treatment; 14 of them had previously been treated elsewhere with the broad-spectrum antibiotics, aureomycin, or oxytetracycline. Amebic liver abscess complicated the dysentery in 6 of the 42 patients with amebic dysentery. The clinical symptoms rapidly subsided, and trophozoites and cysts disappeared from the stools after treatment with the drug. A course of treatment usually consisted of 40 tablets given over a period of 12 days.

PATHOLOGY

Aneurysmal Bone Cyst. M. Cruz and B. L. Coley. Surg. Gynec & Obst. 103:67-77 (July) 1956 [Chicago].

The literature on aneurysmal bone cyst is reviewed and the characteristic clinical, roentgenologic, and microscopic features of the lesion are presented. Twenty cases from the bone tumor department of the Memorial Center for Cancer and Allied Diseases are reported. There is sufficient evidence to support the theory that it may not be a true neoplasm and that it is definitely not a traumatically induced hematoma. The lesion is often mistaken for giant cell tumor and less frequently for juvenile bone cyst or bone angioma. The main practical consideration is to distinguish it from the telangiectatic type of osteogenic sarcoma and thus avoid unnecessary amputation. The treatment of choice is surgical eradication by curettage complemented by bone graft whenever necessary. Roentgen therapy should be reserved for surgically inaccessible lesions. Delay in treatment may result in severe damage to bones, joints, and soft parts and may eventually necessitate amputation. The authors have not observed any cases of spontaneous regression, and there are no well-documented examples of it in the literature.

BOOK REVIEWS

The Management of Menstrual Disorders. By C. Frederic Fluhmann, B.A., M.D., C.M., Clinical Professor of Obstetrics and Gynecology, Stanford University School of Medicine, San Francisco. Cloth. $8.50. Pp. 350, with 121 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1956.

This is the author's second book on menstrual disorders; the first one appeared in 1939. Even though some of the data and illustrations of the first book have been retained, this is a new book, with the emphasis on clinical management. The first chapter, which is most interesting, deals with a historical review of the concepts of menstruation. Fluhmann says that a negative influence is probably responsible for menstruation, not a substance that induces the bleeding. This formed the basis of Edgar Allen's "estrogen-deprivation" theory of menstruation. It is generally believed that the cyclic bleeding of Old World monkeys is the only variety that is identical with menstruation in the human being, but the author mentions the African "elephant shrew," a small rodent that some investigators believe undergoes a true menstrual process. Fluhmann is opposed to the use of vaginal tampons during menstruation when there is an intact hymen, and he says there is a real danger from a forgotten tampon in women who have had children. A simple, useful classification of disorders of menstruation and abnormal uterine hemorrhage is presented in which the main divisions are (1) ovulatory cycles, (2) anovulatory uterine hemorrhage, and (3) arrhythmic uterine hemorrhage. Each of these headings is further subdivided. A table of treatment of dysmenorrhea prepared by Erle Henriksen shows that good results were obtained in 79.2% of patients treated by a wide variety of procedures. This figure was reached after consulting 121 reports on the use of 93 different substances.

A chapter of great value to physicians in practice deals with clinical usage and commercial preparations of sex hormones. In this chapter are listed practically all the hormonal products that are available commercially, the names of the manufacturers, and the doses. The author uses the suffix "tropic" in preference to "trophic" and gives four reasons for this. He uses the term "progestins" to include not only purified progesterone but also natural and synthetic substances with luteoid properties or a chemical relationship. This scholarly book is full of valuable information about menstruation and its disorders. It is exceptionally well written. The data presented are based not only on the vast literature on this subject but also, and in great part, on the extensive and important investigations made by the author in the last 30 years. The lists of references at the end of each chapter are well chosen; the illustrations are numerous, clear, and instructive; and the book is well printed and sturdily bound.

Ciba Foundation Symposium Jointly with the Physiological Society and the British Pharmacological Society on Histamine. In honour of Sir Henry Dale, O.M., G.B.E., M.D. Editors for Ciba Foundation: G.E.W. Wolstenholme, O.B.E., M.A., M.B., and Cecilia M O'Connor, B.Sc. Cloth. $9. Pp. 472, with 133 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., Portman Sq., London, W.1, England, 1956.

Almost 50 years ago Sir Henry Dale showed that the injection of histamine into a normal animal produced symptoms essentially identical with those of anaphylactic shock. This fascinating substance has been ultimately connected with the mechanism of the allergic reaction and inflammation and with some other bodily processes. Many men have spent almost a lifetime studying phases of activity of this substance and its source, site and manner of action, release, and inactivation. In the last few years this work has been intensified, and, with newer chemical methods, isotope labeling, chromatography, and other modern techniques, progress in information about the significance of histamine has been rapid. This book constitutes a report of the papers and discussion on histamine held at a symposium in April, 1955, at the Wellcome Foundation and at the Ciba Foundation in London. The participants were outstanding investigators on this subject from many parts of the world. Among them were Sir Henry Dale, in whose honor this symposium was held; William Feldberg and W. D. M. Paton of London, England; Charles Code of the Mayo Foundation, Rochester, Minn.; J. H. Gaddum of Edinburgh, Scotland; F. C. McIntosh of Montreal, Canada; Floyd McIntire of North Chicago, Ill.; M. Rocha e Silva of São Paulo, Brazil; Bernard N. Halpern of Paris, France; E. A. Zeller and Richard Schayer of Chicago; and many others.

The book deals with the occurrence of histamine in the body, release of histamine, the origin and significance of histamine in the body, the origin and fate of histamine in the body, and the location of histamine in the body. The first three parts, presented at the Wellcome Foundation, contain no discussion. The last two parts, presented at the Ciba Foundation, contain extensive discussion by the participants. Many of the papers contain material hitherto unpublished. The discussions, which add immensely to the value of the book, give the reader the benefit of actual attendance at these symposiums and the privilege of listening to an exchange of ideas by these masters. This book represents the world's knowledge about the subject of histamine. For those interested in allergic processes, hypersensitivity phenomena, inflammation, the biochemistry of such an important substance, and physiology and biochemistry in general, this book is invaluable.

Youth: The Years from Ten to Sixteen. By Arnold Gesell, M.D., Frances L. Ilg, M.D., and Louise Bates Ames, Ph.D. From Gesell Institute of Child Development and from Yale Clinic of Child Development. Cloth. $5.95. Pp. 542. Harper & Brothers, 49 E. 33rd St., New York 16, 1956.

This is the third volume in a series on the personality development of children. The other two are "Infant and Child in the Culture of Today" (1943) and "The Child from Five to Ten" (1946). This study is an analysis of 115 children who were seen repeatedly throughout adolescence and 50 children who were seen at only one age. Thus, from 60 to 88 children were observed at each age. Altogether there were 550 contacts with these children over a period of 12 years. No attempt has been made to determine a norm or average but only to establish the sequence of events observable during the development of a personality. The book is divided into three major portions. The first is largely introductory and explanatory; the second gives a complete picture of adolescent thinking and behavior during the years designated; and the third reveals the trends of maturity by describing the observed sequences of growth in a longitudinal perspective throughout the seven-year period for each of nine major areas of behavior development. These areas include the total action system, self-care and routines, emotions, the growing self, interpersonal relationships, activities and interests, school life, ethical sense, and philosophical outlook. By this technique, one is able to compare a child in one age zone with a child in another age zone in terms of similarities and differences, as well as to observe the changes that characterize developing maturity in each of the nine areas named. Anyone concerned with youth should profit by having this volume available for ready reference, since it is a careful description of the characteristics of youth based on extensive study by skilled observers.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

USE OF POLIOMYELITIS VACCINE AFTER EXPIRATION DATE

To THE EDITOR:—*Please comment on the efficacy of poliomyelitis vaccine used one or two months past its stated expiration date. For several months, only expired vaccine was available to us in this community and we were reassured by the public health department that efficacy of the vaccine was retained. Recently, certain drug houses have warned against such a product. In the event that the vaccine used under these conditions is nonefficacious, should the injection be repeated?*

John R. Eggleston, M.D., Danville, Va.

ANSWER.—Unpublished studies on vaccine stability indicate no detectable reduction in potency over the interval indicated when storage was at the prescribed temperature for normal refrigeration.

IODIZED OIL AND BRONCHIECTASIS

To THE EDITOR:—*What is the rationale of using instillations of iodized oil (Lipiodol) into the tracheobronchial tree for the treatment of bronchiectasis?*

R. R. Grayson, M.D., Perryville, Mo.

ANSWER.—A number of years ago intratracheal injections of iodized oil were recommended and quite widely used in the treatment of bronchiectasis. The results were disappointing. Occasionally a patient was markedly benefited, but most patients noticed little if any improvement. The procedure has now been almost completely abandoned. The instillation of antibiotic solutions and the inhalation of antibiotic vapors or dusts, together with the use of such sputum solvents as Alevaire and Tryptar, are much more effective.

HYPERTHYROIDISM

To THE EDITOR:—*A 30-year-old woman, para 2, gravida 2, complained of swelling of the neck, "stary eyes," tired feeling, nervousness, and pain over the heart for one year. Examination revealed a soft, smooth, palpable thyroid with moderate exophthalmos; areas of vitiligo of the neck and hands; pulse rate, 112 per minute; temperature, 98.6 F (37 C); basal metabolic rate, +44%; and urine and complete blood cell count, within normal limits. She was placed on therapy with propylthiouracil, 100 mg. three times a day, and strong iodine (Lugol's) solution, with pulse rate dropping to 84 per minute in about one month. Treatment with strong iodine solution was stopped, and in two months the pulse rate was down to between 66 and 72 per minute. The medication was diminished to 50 mg. three times a day and in another month to 50 mg. daily. Seven months after start of medication, she was placed on therapy with 50 mg. every other day, until the past four months, when she was getting 50 mg. every third day. After more than two weeks with no medication, radioactive iodine uptake was 70%, showing a moderate hyperthyroid condition. The pulse rate has remained down to 72 to 80 per minute, the exophthalmos has markedly diminished, skin pigmentation has cleared remarkably well, and the patient feels well and has gained weight. What is the next procedure?*

Louis L. Dolinsky, M.D., Woodside, L. I., N. Y.

This inquiry was referred to two consultants, whose respective replies follow.—ED.

ANSWER.—Too much reliance should not be placed on an increased uptake of radioactive iodine as indicating persistence of hyperthyroidism, particularly when the patient has recently been taking an antithyroid drug, because the antithyroid drug in itself can increase the uptake even of a normal thyroid. In the absence of any clinical evidence of recurrence of the hyperthyroidism, it might be best to give no further treatment for the present but to keep the patient under close observation. If frank clinical recurrence of the hyperthyroidism takes place, the choice lies between another trial on medical management, to which the patient responded very well before, elective thyroidectomy after the hyperthyroidism has been again controlled by use of a combination of iodine and propylthiouracil, or treatment with radioactive iodine. There would be little agreement among authorities in the field as to which of the three methods would be preferable in such a case, and the decision would probably have to be based to some degree on the availability of the various methods.

ANSWER.—Since your patient is clinically euthyroid at this time, this consultant would not advise surgery. It would be desirable to have other parameters of thyroid function, including determination of basal metabolic rate and, if feasible, a protein-bound iodine determination. The patient could then be observed for a month and the studies repeated. If, according to these parameters and the clinical picture, she is still hyperthyroid, a prolonged course of propylthiouracil therapy for as long as a year would be indicated, particularly since the patient made such an excellent response previously. If at any time the patient becomes markedly hypothyroid, this medication could then be stopped sooner.

IMMUNE GLOBULIN AND SALK VACCINE

To THE EDITOR:—*What is the effect of an attenuative dose of immune globulin on the antibody response in poliomyelitis if given during the course of immunizing with Salk vaccine? The patient in question was given an attenuative dose of measles immune globulin about one week after the second Salk injection (1 cc.). A local pediatrician has criticized this and told the patient's parents that the "measles shot" cancelled out the second Salk shot. Is this true?*

M.D., Tennessee.

ANSWER.—Passively administered antibody, through the use of immune globulin, in no way affects antibody formation as a result of poliomyelitis vaccine. The passively acquired antibody disappears in about six weeks—but, even during the period of retention, it in no way interferes with the antibody-inducing capacity of the vaccine.

RECURRENT PERIVULVAR ABSCESSES

To THE EDITOR:—*A 3-year-old girl for the past year has had recurrent perivulvar and perirectal abscesses. Her mother has been similarly involved over the same period of time. Both have been treated at times with various antibiotics with resolution of the abscesses, only to have them recur weeks or months later. Recently, after treatment of the little girl with antibiotics, Pseudomonas organisms were cultured from the abscess and an autogenous vaccine was prepared. What other suggestions would there be for therapy of this condition?*

Ronald Germain, M.D., Cincinnati.

ANSWER.—First, see which antibiotic best kills the organism by culture and give this antibiotic over an extended period of time. At the same time, give one of the safer sulfonamide drugs. Next, the urine should be checked for sugar. Local causes of irritation in the bladder, urethra, vagina, and rectum must be accounted for, i. e., Trichomonas or Candida (Monilia) organisms, foreign bodies, or worms. If the condition continues after the above routine, the blood proteins can be checked for globulin, especially gamma globulin. Some cases are reported where administration of gamma globulin helps stop the series. Until the irritation can be controlled, application of cold wet packs with Burow's solution (1 teaspoonful to one 8-oz. glass of water) usually cuts down the itching and burning that causes scratching and transfer of organism to another area. Hand cleanliness is also of some importance, especially under the nails. One should not lose sight of other possibilities, namely, improper or incomplete laundering of underclothing, allowing urine, soaps, detergents, or abscess material to remain

U. S. Employee Health Insurance Plan Studied • •
Wider Dissemination of Scientific Reports Planned • •
PHS Regular Corps Examinations Scheduled • •
Nonfederal Hospitals Aid in Indian Medical Care • •

FEDERAL EMPLOYEE HEALTH INSURANCE

At the request of Chairman Tom Murray of the House Post Office and Civil Service Committee, the U. S. General Accounting Office is attempting to gather information that may eventually lead to establishment of a basic payroll deduction health insurance plan for federal civilian employees. A previous attempt to set up such a plan, but without payroll deductions, failed earlier this year, after which a government-paid major medical cost insurance plan was proposed. This also failed to interest Congress. Mr. Murray asked the Government Accounting Office to complete its study and by the end of the year to report back to the House committee, which late in the session held hearings on federal employee health insurance but did not attempt to report out a bill.

At the hearings, the Civil Service Commission and a number of federal employee unions supported legislation for major medical cost insurance for U. S. employees, with the federal government paying the full cost. However, the proposal lost out because of opposition from Blue Cross, Blue Shield, the American Hospital Association, and some national labor leaders. Opponents of the catastrophic coverage plan argued that the first step must be provision of basic health insurance, comparable to that offered by industry, with payroll deductions. At that time it was understood that the administration refused to approve payroll deductions.

To comply with Mr. Murray's request for information on the "feasibility and estimated probable cost of administering a payroll deduction system for basic medical protection for federal employees," the Government Accounting Office has mailed a questionnaire to all groups interested in financing of basic payroll deduction health insurance, including Blue Cross and Blue Shield, the insurance industry spokesmen, federal employee unions now supplying this type of coverage, and cooperative health insurance organizations.

The questionnaire asked the carriers to answer such questions as those that follow. 1. What methods should be used to keep payroll offices notified as to the beginning and ending of individual coverage? Would payroll offices be expected to maintain any information other than name and amount of premium deducted? 2. How often would remittances have to be made? Could a central clearing house for all information and remittances be practical? Would the cost of such a setup result in increased premiums or decreased benefits to the employees? Other questions concern such points as coverage during periods of leave of absence, the responsibility of the government other than deduction of premiums from payroll, and local problems that might cause difficulties in the over-all operation of a national payroll deduction system. As brought out in earlier discussion of the problems of basic health insurance coverage through payroll deductions, the numerous and varied plans now in operation and supported entirely by the employees, are a major complication.

GOVERNMENT-SPONSORED RESEARCH

Steps are being taken by three agencies of government to assure wider dissemination of scientific reports on basic research issued annually by organizations doing government-sponsored research work. Alan T. Waterman, director of the National Science Foundation, announced the new program and said cooperating with it would be the Library of Congress and the Commerce Department.

Dr. Waterman explained the program is designed to assist any research scientist to (1) learn what unclassified scientific reports on government research are being issued in his field and how to obtain them, (2) obtain on a subscription basis a report-announcement service that automatically will keep him informed regarding the bulk of such reports in fundamental research and through which he can purchase copies of listed reports, and (3) obtain access to a well-catalogued reference collection of unclassified scientific reports. "Federally supported basic scientific research of an unclassified nature henceforth will be made more widely available to scientists everywhere," Dr. Waterman declared. He estimates some 20,000 such reports are issued annually by various organizations. Persons interested in the program may write the Government Research Information Clearing-House, National Science Foundation, Washington 25, D. C.

PHS MEDICAL APPOINTMENTS

The Public Health Service has announced that competitive examinations for appointment of medical officers in the PHS regular corps will be held in various

---

From the Washington Office of the American Medical Association.

sections of the United States Nov. 27-30. The appointments provide opportunities for careers in clinical medicine, research, and public health. Ranks will be assistant surgeon and senior assistant surgeon, equivalent to Navy ranks of lieutenant (j. g.) and lieutenant. Applications may be obtained from the Chief, Division of Personnel, PHS, Department of Health, Education, and Welfare, Washington 25, D. C. They must be returned no later than Oct. 13.

Pay for both grades, with dependents, is $7,498 per year. The PHS said benefits include periodic pay increases, 30-day annual leave, medical care, and both disability and regular retirement pay. Requirements are U. S. citizenship, age 21, and graduation from a recognized medical school. In addition, assistant surgeon's rank requires seven years of collegiate and professional training, and senior surgeon, 10 years. Active duty as a PHS officer fulfills the obligation of Selective Service.

INDIAN MEDICAL CARE

The federal government has contractual arrangements with about 130 nongovernmental hospitals in the provision of medical care for Indians. Similar arrangements are in effect with approximately 20 county and state sanatoriums and 10 state and other mental hospitals. In all, some 1,800 beds are thus provided for Indians in other than government facilities. The total number of beds in Public Health Service Indian hospitals is 3,815 in 56 facilities. These statistics are supplied by the Department of Health, Education, and Welfare in a new pamphlet titled "Facts About Indian Health." It notes that "in many respects the health conditions of American Indians are similar to those which prevailed generally a half century ago, when knowledge of sanitation, hygiene, and curative measures was too limited to prevent undue illness and early loss of life."

Now health conditions among the Indians are improving, the report notes. For example, whereas more than 200 of every 100,000 Indians in the U. S. died of tuberculosis during the early 1940's, the 1953 death rate was 62 per 100,000. The death rate from pneumonia and influenza has been reduced from 161 to 108 per 100,000 since 1943. The PHS took over administration of medical and health programs for Indians July 1 of last year. "To many thousands of American Indians and Alaska natives, the Public Health Service fills the role of family doctor and community hospital." The report states, "Most of the general hospitals are small facilities with less than 40 beds, and all of them provide extensive outpatient services."

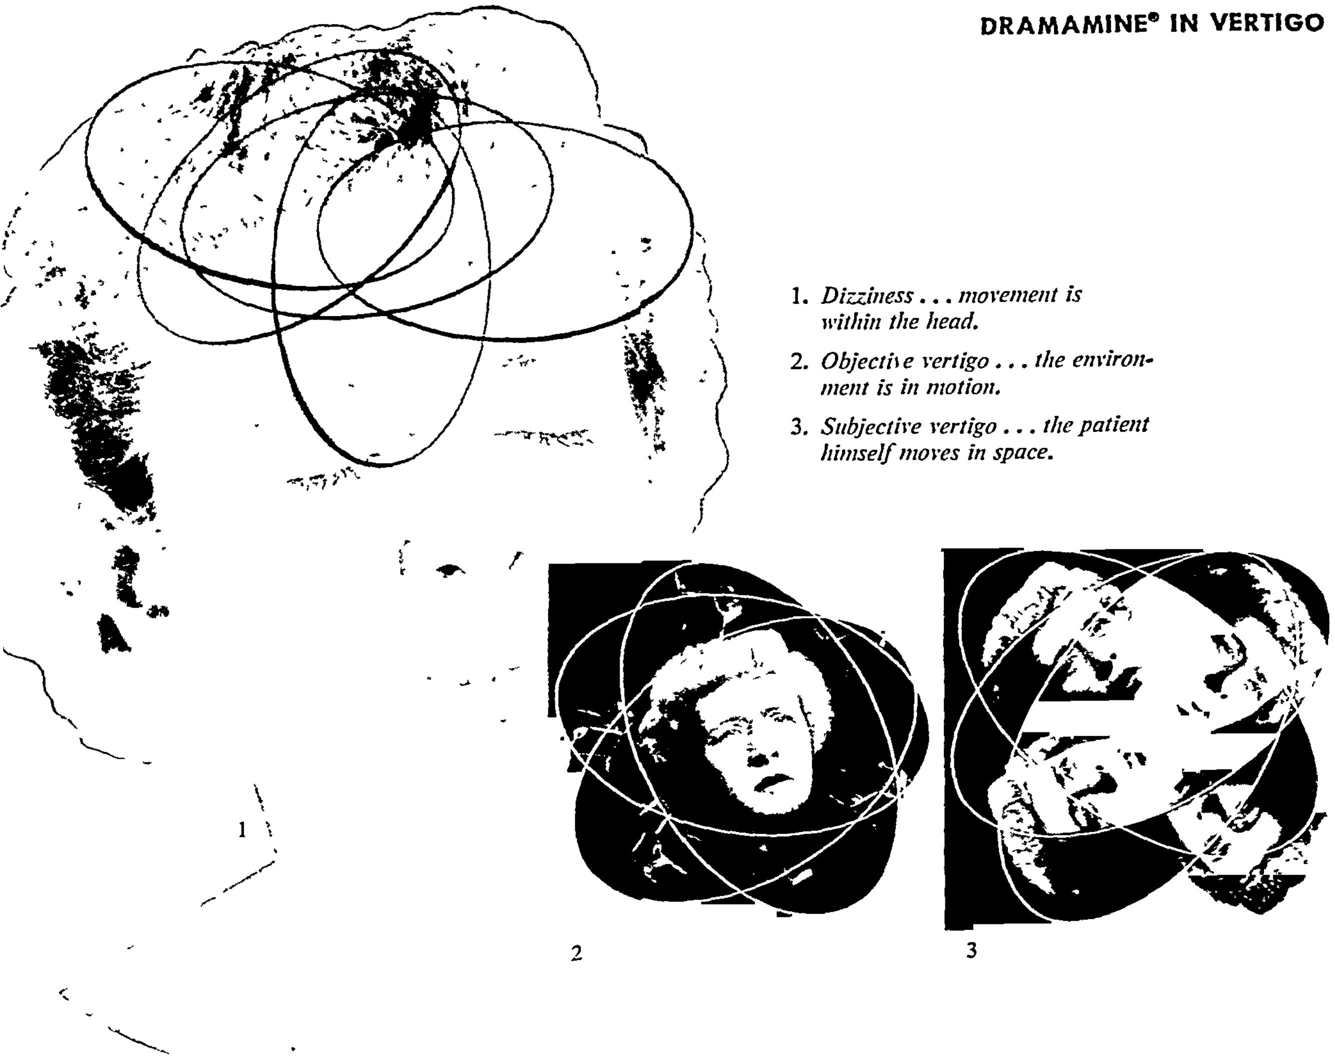
MISCELLANY

The U. S. Office of Education estimates that 58.1% of funds for public education are obtained through local property taxes as against 37.4% through state taxes on incomes, sales, and other business activity a 4.5% from the federal government. The agency pred that college-university enrollment will increase from present 3,200,000 to about 6,400,000 by 1970. " sources for the education of young people beyond high school will have to be considerably expanded the years ahead," the office adds. . . . Reserve med officers and officers of the Medical Service Corps inactive duty may earn reserve credit points for att ance at daily sessions of the 63rd annual me the Association of Military Surgeons. The meeting opens Nov. 12 in Washington, with Rear Winfred P. Dana, M. C., U. S. N., presiding. The fense Department said point credits will be aw eligible reservists on the basis of one point for day of attendance, providing the session is two hours in duration. . . . The first annual National C Defense Week ended Sept. 15, after civil defense ganizations in various parts of the nation staged s cial events, such as mass feedings, test evacuations, rescue, fire, and warden drills. President Eisenh in his proclamation described civil defense as "c the greatest deterrents to an attack on this nat . . . The first fall-off of the year in poliomyelitis ca occurred the week ending Sept. 1, when 566 ca were reported to the PHS, compared with 5 the previous week. Last year the peak week oc at approximately the same time, although the week in September is the median peak week last five years. Regarding the decline, the PH marks: "Due caution should be observed in d conclusions about the current poliomyelitis sea

PERSONNEL

Dr. Robert J. Anderson, a career Public Health cer, has been named chief of the PHS Communic Disease Center in Atlanta, Ga. He replaces Dr. Th dore J. Bauer, who will become deputy chief of t Bureau of State Services. Dr. Anderson has been s ing as assistant chief of the PHS division of spe health services. In this Washington post he has dire operational research in a number of disease con activities. The PHS also announces the appoint of Dr. A. L. Chapman as chief of the division of spe health services, succeeding Dr. Seward E. Miller, w has taken a leave of absence to accept a position at University of Michigan as director of the Institute Industrial Health. Dr. Chapman previously was me cal director of the regional office of HEW in N York City. . . . The new executive officer of Wa Reed Army Hospital is Col. John H. Voegtly. Form chief of the department of atomic casualties at Wa Reed Army Institute of Research, he succeeds C Joseph R. Vivas, who has been assigned to Madig Army Hospital, Tacoma, Wash.

DRAMAMINE® IN VERTIGO



1. *Dizziness . . . movement is within the head.*
2. *Objective vertigo . . . the environment is in motion.*
3. *Subjective vertigo . . . the patient himself moves in space.*

Types of Vertigo:

Effective symptomatic relief of inner ear dysfunctions.

The disagreeable sensations of dizziness which physicians are frequently required to explain to patients have been described by Simonton[1] as varying from a slight sensation of confusion to severe vertigo.

While dizziness or giddiness is classified as a sensation of unsteadiness with a feeling of movement within the head, in vertigo the environment seems to spin (objective vertigo) or the body to revolve in space (subjective vertigo). Labyrinthine disturbances are likely to cause a sensation of rotation. Among the more common causes of dizziness or vertigo, this author lists: Damage to the vestibular nuclei or tracts in the central nervous system, involvement of the vestibular end organs by disease of the ear, Ménière's disease, toxicity of drugs, ocular vertigo from sudden diplopia, visual field defects, looking down from heights and motion sickness due to hyperactive labyrinthine reaction from riding in vehicles.

Dramamine (brand of dimenhydrinate) has proved effective in treating many of these disturbances. The widely accepted indications for Dramamine include: Motion sickness, the nausea and vomiting associated with certain drugs, electroshock therapy and narcotization; vestibular dysfunction associated with streptomycin therapy; the vertigo of Ménière's syndrome, hypertensive disease and that following fenestration procedures, labyrinthitis and radiation sickness. G. D. Searle & Co., Research in the Service of Medicine.

Manuel Garcia's Contribution to Mirror Laryngoscopy

The light that revealed the larynx had smoldered for half a century before Manuel Garcia reflected the sun's rays to reveal the hitherto darkened chambers of this organ. . . Attempts to devise an apparatus to visualize the vocal cords were made by physicians who . . . wished to see the interior of the larynx so that they might diagnose and intelligently treat diseases of that organ. . . . Manuel Garcia, a singing teacher, also manifested an interest in the larynx but for a different reason. He probably was as *familiar with the anatomy of the larynx* as any physician of his time for he had dissected it on numerous occasions. He was consumed with a desire to see "a healthy glottis in the very act of singing," so that he might perfect his anatomical and physiological studies. Gratification of this was made possible while he was on vacation. . . . [His account reads as follows:] "One September day, in 1854, I was strolling in the Palais Royal, preoccupied with the ever-recurring wish so often repressed as unrealizable, when suddenly I saw the two mirrors of the laryngoscope in their respective positions, as if actually present before my eyes. I went straight to Charriere, the surgical instrument maker, and asked if he happened to possess a small mirror with a long handle, was informed that he had a little dentist's mirror, which had been one of the failures of the London Exhibition of 1851. I bought it for six francs. Having obtained also a hand mirror, I returned home at once, very impatient to begin my experiments. I placed against the uvula the little mirror (which I heated in warm water and carefully dried), then, flashing upon the surface with a hand mirror a ray of sunlight, I saw at once to my great joy, the glottis open before me and so fully exposed, that I could perceive a portion of the trachea. When my excitement had somewhat subsided, I began to examine what was passing before my eyes. The manner in which the glottis silently opened and [illegible]t, and moved in the act of phonation, filled me with wonder."

[illegible]arcia's wish had been gratified. He had seen a living larynx the act of phonation. Here was a golden opportunity to learn about the physiology of the larynx and to enhance his knowledge of its anatomy. He had a very tolerant throat and as a singer had learned to keep the base of his tongue down. He began to perform autolaryngoscopy making observations on his own larynx during phonation and singing. It is interesting to note that Garcia was the first to conceive the idea of autoscopic examination He became proficient with the mirror and soon studied the larynges of other singers. Both hands were required to manipulate the mirrors and therefore the examiner could not hold the tongue. No one had enlisted the patient to provide this important aid. . . . Garcia presented a paper on "Observations on the Human Voice" *before the Royal Society* of London on May 24, 1855. He explained "that tones are elicited when the stream of expired air is divided into a series of uniformly recurring blasts," which he called explosions, by the regular vibrations of the vocal cords. The closed cords are pushed apart by the escaping air, but because of their elasticity they immediately come together again. When they are in close apposition the tones are pure or brilliant; when contact is incomplete the tones are veiled. He recounted how the different registers, chest, falsetto, and head tones, are entirely determined by the shape of the cords and the extent to which they vibrate; and how the "breaking" of a boy's voice as he approaches puberty is due to their elongation, consequent upon a growth of the laryngeal cartilages that produces the prominent "Adam's apple." Garcia was the first to make and describe these observations.—L. H. Clerf, M.D., Manuel Garcia's Contribution to Laryngology, *Bulletin of the New York Academy of Medicine*, August, 1956.

American Indian Medicine

It is not a matter of wonder that Indians should be plagued with fears and horrible imaginings. . . . Most Indian tribes had a precarious living. They had to contend with the elemental forces of nature and with wild animals. . . . It was easy for the Indian to believe in a god of lightning, thunder or whirlwind and to imagine that animals could communicate with him and influence his life. From this arose the custom of wearing amulets to ward off evil spirits, and the belief in totems. . . .

Harlow Brooks, born in Minnesota, played as a frontier child with red children, but later studied medicine. . . Speaking before the Section of Historical and Cultural Medicine of the New York Academy of Medicine on October 26, 1928, Dr. Brooks said thus: ". . . Back as far as history and tradition go, we know that the Medicine man has always held a position in the tribe and in its social standards far more powerful and important relatively than the white medicine man has yet attained. Many of the great Indians in history have been medicine men:" . . .

[An extract of "The Medicine Man," a paper read before the Bathurst and Rideau Medical Association, Jan. 20. 1886. by Robert Bell, B.A., Sc., M.D., LL.D., Assistant director of the Geological Survey of Canada, reads as follows:]

"*In former times the great medicine-men among these Indians* devoted their whole lives to the study and practice of their art, and even yet (1886) it receives the greater part of their attention. They were accustomed to do no common work, but lived at the expense of the band they were amongst. They had great influence with the people, principally from playing upon the superstitious fears, which had become inculcated by their own class from generation to generation." . . .

Dr. Bell mentions 15 plants used medicinally *by the Ojibway* Indians. One of them is the spruce tree. A decoction of its leaves is used internally as a remedy for scurvy. This was used with signal success by Jacques Cartier and his men at Quebec in 1535 and by Miles Macdonnell and the Selkirk settlers at York Factory in 1812-13. Another of the plants is senega or snake root which . . . is used in cough medicines. . . . Janet Carruthers, a resident nurse on Indian reserves in Northwestern Ontario and Alberta [writes] in the March 1952 issue of "The Beaver" under the title of "Land of the Ojibway":

"Many of the Ojibways' ills are taken care of by the medicine-men, and the medicine-man should not be entirely discounted; nor should he be confused with the philanderers and quacks who exploit the innocent with mystics and charms. Knowledge of healing qualities of plants has come to him from far back in his race. Long before salicylates were listed in a scientific pharmacopoeia he knew the medicinal value of willow-bark. The liniments he makes from pine needles and the infusions he concocts from hepatica, sarsaparilla root and wintergreen are all ancestors of our store-dispensed medicine." . . .

One may say that the Indian medicine-men had a considerable knowledge of the healing properties of herbs, minerals and animal substances, that they could treat wounds and fractures, and they practised psychosomatic medicine long before that term was known to white practitioners. The medicine-men attained their place in the tribe only after long preparations and examinations, they were the intellectuals in their community and they were held in high esteem.—Ross Mitchell, M.D., North American Indian Medicine, *Manitoba Medical Review*, April, 1956.

"SILO-FILLER'S DISEASE"—A SYNDROME CAUSED BY NITROGEN DIOXIDE

Thomas Lowry, M.D.
and
Leonard M. Schuman, M.D., Minneapolis

• *Four patients who entered silos within a day or two after filling with corn silage noted irritating fumes and experienced respiratory symptoms of varying degrees of severity. A period of failure to improve was followed by a period of worsening that ended with death on the 27th and 30th days in two cases. The disease was halted in the other two cases by treatment with prednisone. Intramuscular injections of this drug in 10 mg. doses three times daily were followed by prompt and striking improvement, especially in one case. Chemical evidence showed that the toxic gas was probably nitrogen dioxide, a gas capable of causing early pulmonary edema with subsequent bronchiolitis fibrosa obliterans. The bronchiolitis gives a roentgenogram marked by innumerable discrete nodular densities in the lungs and indistinguishable from that of acute miliary tuberculosis; its nature was verified at autopsy in the two fatal cases. Oxygen gave only symptomatic improvement, and the effects of bronchodilators and antibiotics were only temporary. Prevention of silo-filler's disease depends on adequate ventilation, on means of keeping people and animals from straying into dangerous spaces adjoining a silo, especially during the 7 to 10 days after the silo is filled, and on a wider recognition of the danger.*

The inhalation of irritating fumes encountered in or near freshly filled silos has recently been shown [1] to cause serious and potentially lethal respiratory disease in man. The agent producing this condition is nitrogen dioxide, which is always partially polymerized to nitrogen tetroxide. These two gases are both considerably heavier than air, and both are highly toxic upon inhalation. Since the observation by one of us (T. L.) in September, 1955, of two fatal cases[2] we have attempted to gain a comprehensive view of "silo-filler's disease." This term, as employed in the present report, designates any bronchial or pulmonary condition produced by the inhalation of oxides of nitrogen derived from fresh silage. The pathological changes found at autopsy in lungs and bronchi damaged by this toxic gas vary widely with the amount of nitrogen dioxide inhaled. Correspondingly, clinical findings in the patients differ greatly; it is clear that our meager experience has permitted close study of but one of several different clinical and pathological entities that may be produced by this gas.

The following account is, for the most part, an attempt to describe one form of silo-filler's disease that is, itself, a clear-cut, distinct clinical and pathological entity. Typical bronchiolitis fibrosa obliterans has occurred in four individuals exposed to silage fumes under essentially identical circumstances. Correlation of data derived from a study of the four cases has permitted us to outline the clinical features of this hitherto undescribed syndrome. Two additional instances of silo-filler's disease[1b] have recently been reported, each of which differs greatly from the rather closely similar pattern of our four cases. Yet these two cases clearly belong in the same general category and fit the definition given above. We are led, by these combined pieces of evidence and by a study of the pertinent medical literature, to formulate hypotheses concerning other entities that, together with bronchiolitis obliterans, are to be regarded as clinical types of silo-filler's disease. The future recognition of additional similar cases will require that physicians be aware of the condition as a possibility and also that they be acquainted. in a very general manner. with its basic clinical characteristics.

Although the medical literature contains a number of references[3] to fatal bronchiolitis obliterans resulting from accidental inhalation of nitrogen dioxide in such places as industry and the chemical laboratory, we have been unable to find any record of bronchiolitis in the human caused by exposure to gas or fumes evolved by fresh silage. A probable explanation for the lack of earlier reports is the apparent rarity of this condition; in all likelihood, the production, in a silo, of nitrogen dioxide concentrations sufficient, when inhaled, to cause bronchiolitis depends upon

a particular and unusual combination of chemical circumstances. Experimental work now in progress should eventually yield much more information concerning these circumstances.

We wish to emphasize the fact that the observations to be reported do not imply need for any change in current silage-making methods. It is our intent, rather, to describe a distinct, serious, physical hazard that can readily be avoided and to make the essential data available to physicians generally (especially to those practicing in rural areas) prior to the completion of another growing season. The disease under consideration is a clear-cut, specific entity, not previously described nor recognized as an occupational hazard in agriculture. It produces a striking clinical syndrome. The roentgenographic findings may be indistinguishable from those of other well-established pulmonary diseases such as miliary tuberculosis. A history of recent exposure to irritating silage fumes is the essential evidence that identifies this condition and differentiates it from conditions similar in other respects.

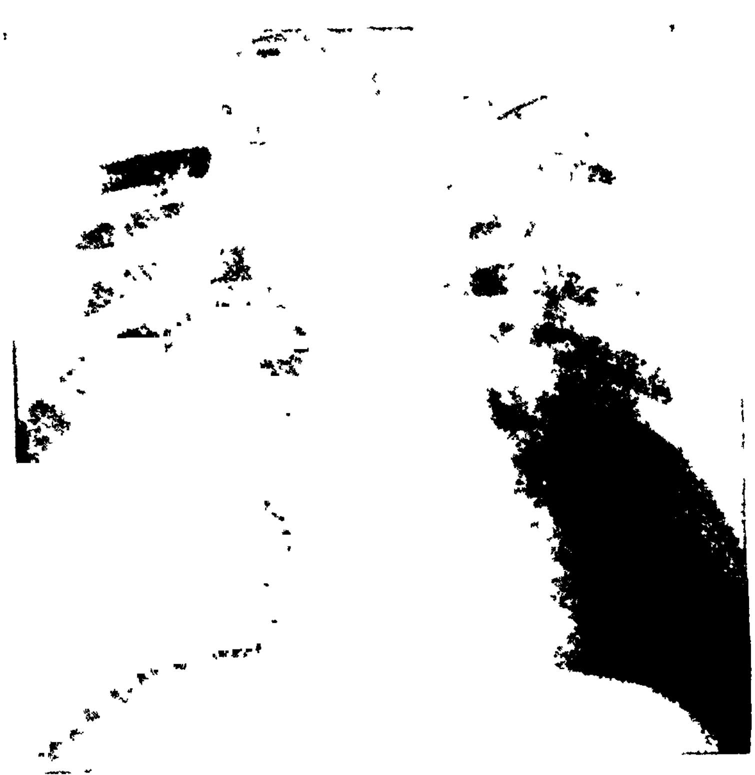

Fig. 1 (case 1).—Roentgenogram made 25 days after exposure to silage fumes and only 5 days before death. Note confluent infiltration of upper lung fields. The numerous discrete nodules throughout remaining lung tissue are not seen in this reproduction.

Since certain clinical features necessarily provide the clues that will permit practicing physicians to recognize silo-filler's disease, one of our cases will be described in detail, whereas the remaining case histories will be briefly summarized. The patients in cases 1 and 2 were observed by one of us (T. L.) during the terminal phase of their illness; those in cases 3 and 4 are reported through the courtesy of their respective physicians.

Report of Cases

Case 1.—A 28-year-old farmer climbed an enclosed ladderway to the top of his silo on Sept. 1, 1955, in order to open the top door for purposes of ventilation. The silo had been filled on the previous day with straight corn silage containing no chemical additives. While climbing this enclosed, nonvented ladder, he noticed an irritating odor, accompanied by oppressive heat and humidity that "almost overcame him" and forced him to climb down without accomplishing his intended task. He came down the ladder coughing and weak; he was nauseated but did not vomit. He coughed intermittently and increasingly from the day of exposure onward, wheezed a good deal of the time, was dyspneic on any exertion, and was noted to be weak, tired, and listless. On Sept. 16, 1955, shaking chills and fever were noted and cough and dyspnea worsened, the patient was finally induced to consult his physician on Sept. 21, 1955. He was given treatment for "pneumonia," but two days later all of the symptoms had increased alarmingly, his cough was incessant, and the slightest exertion or movement now caused him to gasp for breath. On Sept. 24, 1955, he entered Glencoe Municipal Hospital, where he was placed in an oxygen tent and received penicillin together with one other antibiotic the administration of which had been started on Sept. 21, his condition deteriorated further, however, and on Sept. 27, his physician consulted one of us (T.L.) by telephone. In accordance with the suggestion of his physician, arrangements were then made for his transfer by ambulance (and with continuous administration of oxygen) to Northwestern Hospital, Minneapolis.

On admission, the patient was in critical condition. Rectal temperature was 102 F (38.9 C), pulse rate 128 per minute, respiratory rate 52 per minute, and blood pressure 170/80 mm. Hg. Dyspnea was extreme, the respirations were rapid, shallow and gasping in type, and were interrupted frequently by paroxysms of violent, nonproductive cough. Cyanosis was very marked, and, though the atmosphere of an oxygen tent made him slightly less uncomfortable, it did not perceptibly influence his dusky color.

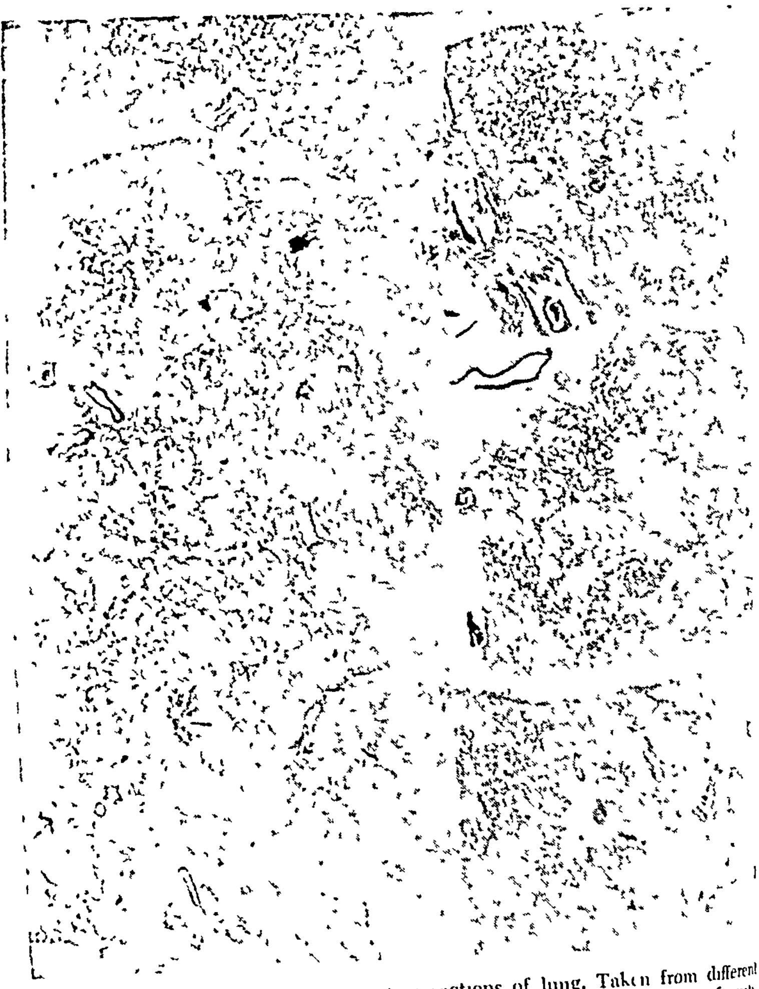

Fig. 2 (case 1).—Representative sections of lung. Taken from different parts of both lungs, these illustrate the extent and remarkable uniformity of infiltration. Both lungs were filled with innumerable small discrete nodules, no portion of either being spared (× 2½).

Physical examination of the chest showed tachypnea, with relative prolongation of the expiratory phase of breathing. The lungs were resonant throughout, but normal vesicular breath sounds were everywhere much reduced. Numerous fine and medium moist inspiratory and expiratory rales were present throughout both lungs; sibilant rales of the asthmatic type, also generalized, were most prominent in the expiratory phase. The heart was of normal size, heart sounds, though very rapid, were normal, and no murmurs were heard. Examination revealed no other abnormalities. The patient was extremely weak and utterly exhausted, so that, although fully conscious, he spoke only single words, and these with considerable effort.

Laboratory studies gave the following findings. The urine was normal except for a faint trace of albumin. Blood studies showed that the hemoglobin level was 14.1 gm. per 100 cc.: the white blood cell count was 26,600, with 85% neutrophils, 13% lymphocytes, and 2% monocytes. The sedimentation rate was 77 mm. in one hour; the carbon dioxide–combining power was 35 mEq. per liter (79 vol. %). Blood cultures were sterile. Sputum showed gram-negative bacilli on smear and paracolon bacilli on culture, but was negative for fungi, both microscopically and on culture. During the patient's four-day hospital stay, the only significantly changing laboratory finding was a progressive rise of the blood carbon dioxide level from 35 to 45 mEq. per liter (102 vol. %). Concomitantly, the serum chloride level decreased from 87 to 82 mEq. per liter and the blood urea nitrogen level rose slightly from 17.5 to 25 mg. per 100 cc. on the day of death. Serum levels of sodium and potassium were normal. X-ray examination of the chest (fig. 1) revealed innumerable nodular densities uniformly scattered throughout the lung fields. These varied in diameter from 1 to 5 mm., and there was confluence of the lesions in the upper one-third of each lung. From a roentgenologic viewpoint, the appearance was consistent with that in miliary tuberculosis or in one of the other conditions capable of producing diffuse nodular infiltration of the lungs. An electrocardiogram on the second hospital day revealed sinus tachycardia, rather tall P waves in leads 2 and 3, and slight irregularity of rhythm due to a "wandering pacemaker."

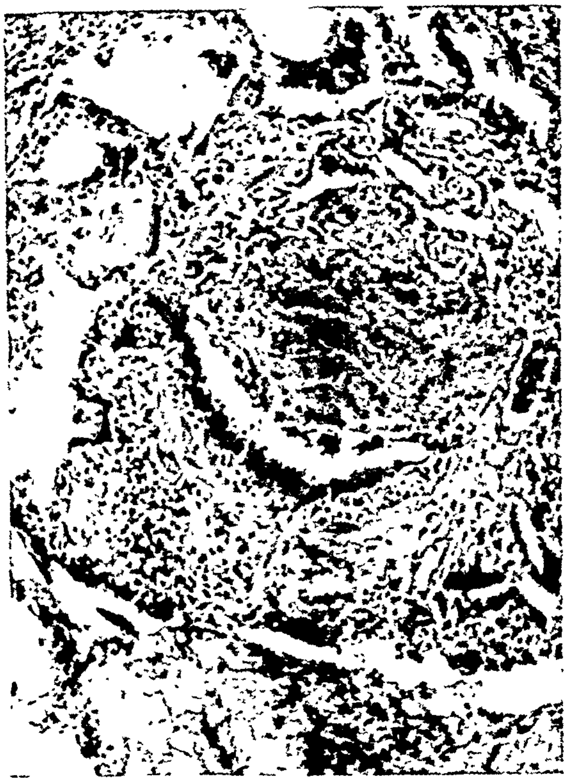

Fig. 3 (case 1).—Cross section through bronchiole, showing lumen almost filled by partially organized fibrin plug. Remnant of lumen is crescentic in shape and is partly lined by epithelium. At upper right, muscular coat is fragmented and plug is firmly attached to the wall (X 100).

At the time of the patient's admission, the clinical picture was that of an acute and widely disseminated pulmonary infection, unlike any of the familiar varieties, together with severe pulmonary insufficiency, which appeared likely to lead rapidly to a fatal outcome. The patient was placed in an oxygen tent; he was given codeine and later meperidine (Demerol) hydrochloride for suppression of his exhausting cough. He received several intravenous doses of aminophylline, which at first seemed to reduce bronchospasm; after the first 12 hours, however, this drug was clearly ineffective. Penicillin, streptomycin, and chloramphenicol (Chloromycetin) were administered intramuscularly in full doses. After a very brief period of slight improvement, the relentless downhill course of the disease continued. Early on Oct. 1, 1955, the patient's condition became rapidly worse, and during that day he became irrational and then comatose. He died on the evening of Oct. 1, 1955, having failed to respond to digitalis, diuretics, or emergency measures. Autopsy revealed no abnormalities elsewhere than in the lungs; these weighed 800 gm. (right) and 700 gm. (left), contained a slight excess of blood and edema fluid, and were filled throughout with innumerable small, discrete, grossly palpable nodules. No portion of either lung was spared. Microscopic sections (fig. 2-5) showed these nodules to be typical lesions of bronchiolitis fibrosa obliterans. The results of complete bacteriological, mycologic, and virologic examinations of pulmonary tissue at the laboratory of the Minnesota State Board of Health were essentially negative. The heart weighed 340 gm. and was normal throughout.

Case 2.—A 31-year-old farmer, brother of the patient in case 1, inhaled irritating fumes on the same day (Sept. 1, 1955), in the same silo chute, and under the same circumstances as his brother. He immediately noted cough and weakness, was nauseated, and vomited. Thereafter he was never totally well but was not incapacitated. He coughed and wheezed intermittently and became gradually more dyspneic. Rapid progression of symptoms began about Sept. 22, 1955, and on the following day he was found to have fever. His physician was consulted on Sept. 24; the patient was hospitalized at Glencoe on Sept. 26. X-ray examination (fig. 6) showed innumerable discrete miliary nodules throughout both lungs, without confluence. His condition, already critical, became rapidly worse. On transfer to Northwestern Hospital, Minneapolis, on Sept. 27, he appeared slightly less gravely ill than his brother (case 1) but became rapidly worse and died in shock and stupor 18 hours after admission. The blood carbon dioxide level was 34.5 mEq. per liter (77 vol. %). Cultures were all negative. Bone-marrow biopsy findings were normal. Autopsy findings were closely similar to those in case 1. The right lung weighed 650 gm. and the left 550 gm.; both contained a slight excess of blood and edema fluid. Microscopic sections of the lungs revealed that they were filled with the tiny nodular lesions of bronchiolitis obliterans, identical with those found in case 1.

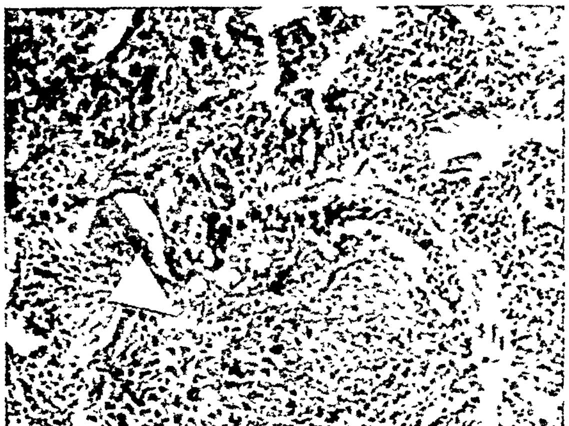

Fig. 4 (case 1).—Further stage in organization of a bronchial plug About half of the muscular coat remains intact but elsewhere has been destroyed (arrows), permitting free ingrowth of fibroblastic tissue. Lumen is obliterated, and no epithelium remains (X 100).

CASE 3.—A 48-year-old male farmer filled his silo with corn silage on Sept. 2 and 3, 1955. He climbed the ladder in the chute Sept. 4 and had to ascend twice because he was nearly overcome by fumes, he was forced to abandon his first attempt After recovering from this exposure, he felt quite weak but stated that he had no cough or dyspnea until Sept. 23, when he developed shortness of breath and diarrhea. The dyspnea progressed rapidly and led his physicians to hospitalize him on Sept. 27. On admission, the patient's temperature was 100 F (37.8 C), his pulse 112 per minute, and respiratory rate 50 per minute He became steadily worse, while receiving antibiotics and oxygen X-ray study (fig. 7) showed diffuse nodular infiltration throughout both lungs. The nodules were larger and the infiltration appeared even more extensive than in cases 1 and 2 On Oct 1, at the suggestion of a consultant, intramuscular administration of 10 mg. of prednisolone (Delta Cortef) three times a day was started. The response was dramatic, and the patient felt better in 12 hours On Oct 3, a roentgenogram showed some clearing of the pulmonary lesions The patient was discharged on Oct. 10, 1955, and has remained well He returned to work about Nov. 1, 1955. Serial x-ray studies of the chest (fig 8) have shown progressive resolution of the nodules, but in March, 1956, tiny nodular densities were still detectable throughout both lung fields.

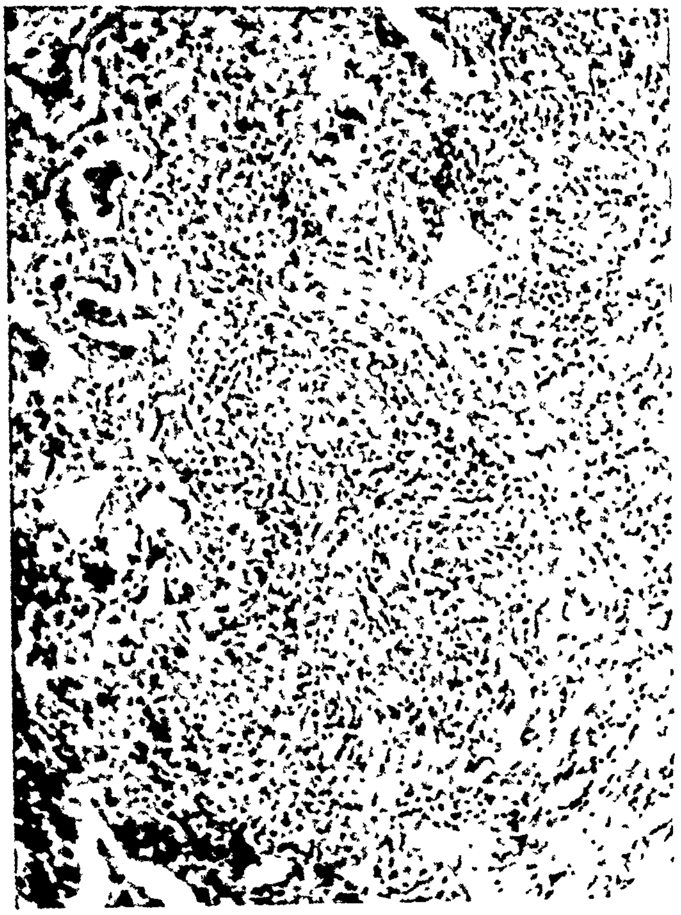

Fig 5 (case 1) —Late stage of obliteration of a bronchiole, whose original location is marked only by two fragments of the muscular coat (arrows). These lie in the midst of proliferating fibrous connective tissue, which is also overgrowing and obliterating the architecture of surrounding lung tissue (X 100)

CASE 4.—A 45-year-old male farmer began to add corn to his silo (still nearly one-half full of alfalfa silage put there in May, 1955) during the morning of Sept. 23, 1955. On Sept. 24, he climbed a ladder in the chute to look for a lost tool, noted irritating fumes and "inability to get air" about half-way up, and was forced to rest before descending. He was almost free of symptoms until Oct. 3. Dyspnea was noticeable then and increased steadily; he first visited his physician on Oct. 14. Breathing was more labored by Oct. 17, and the patient went to the hospital for x-ray study of the chest (fig. 9), which showed extensive, diffuse nodular pulmonary infiltration. He returned home, but was practically unable to move because of dyspnea. At the time of his admission to the hospital on Oct. 20, his temperature was 102.2 F (40 C) and his pulse 112 and respirations 54 per minute; cyanosis was pronounced. He immediately received prednisone in full doses and was given no antibiotic Considerable improvement was noted within 24 hours. By Oct 29, therapy was discontinued, and he was discharged from the hospital on that day. He had employed over-ripe corn as silage and had used heavy nitrate fertilization this year for the first time. He returned to work Nov. 20, 1955. Roentgenograms made at intervals demonstrated resolution of the nodular infiltrate which, however, had not completely disappeared on Jan 30, 1956 (fig. 10), although the patient had disclaimed any residual symptoms for one month previously

Characteristics of Syndrome

The following cardinal points, noted in all four patients. can be considered characteristic of the clinical picture of silo-filler's disease with bronchiolitis obliterans. 1. There is a history of inhalation of irritating gas in or about a silo within a short time (from a few hours to three or four days) after filling is commenced. 2. Cough and dyspnea with a sensation of "choking" and severe weakness are noted immediately upon exposure and do not relent completely during the illness. 3. There is a two-to-three-week period after exposure characterized by a relative remission of symptoms, though some cough, malaise, and dyspnea remain and weakness progresses. 4. Onset of a second phase of illness occurs about three weeks after initial exposure. often accompanied by chills. There is fever, with progressively more severe dyspnea, cyanosis, and cough, which do not respond to administration of antibiotics, oxygen, or bronchodilators and lead to death (or else to the beginning of recovery) three and one-half to six weeks after exposure. 5. Numerous fine and medium moist (bubbling) inspiratory rales are heard over the entire extent of both lungs, together with a few moist expiratory rales and prominence of sibilant,

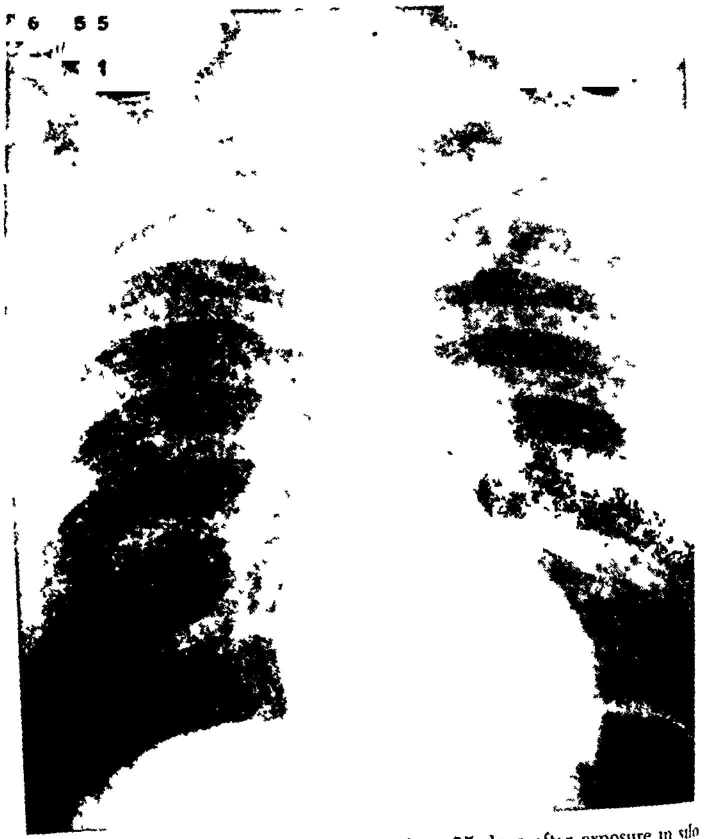

Fig. 6 (case 2).—Roentgenogram of chest 25 days after exposure in silo chute and only 2 days before death. Innumerable discrete nodules are scattered densely throughout both lungs.

asthmatic-type rales during expiration (signifying obstruction of small bronchi and bronchioles). 6. X-ray examination of the chest reveals uniform infiltration of all lung tissue with innumerable discrete nodular densities. The typical roentgenogram cannot be distinguished from that in acute miliary tuberculosis (or any one of the other conditions producing diffuse miliary nodulation in the lungs). Confluence of the lesions may be found in severe and advanced cases (e. g., case 1). 7. Laboratory studies show moderate to marked neutrophilic leukocytosis. In the late stages of the disease, progressive increase of blood carbon dioxide levels, indicating retention of this gas in spite of extreme respiratory effort, is, in our experience, a poor prognostic sign. Results of all other laboratory tests are normal; cultures of blood, sputum, and bone marrow for bacteria and fungi and virus studies are all negative.

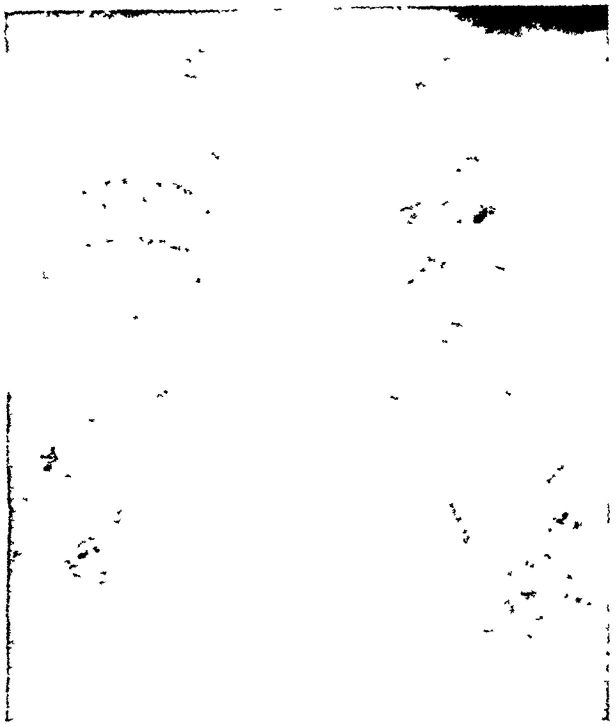

Fig 7 (case 3) —Chest roentgenogram 23 days after exposure to silage fumes

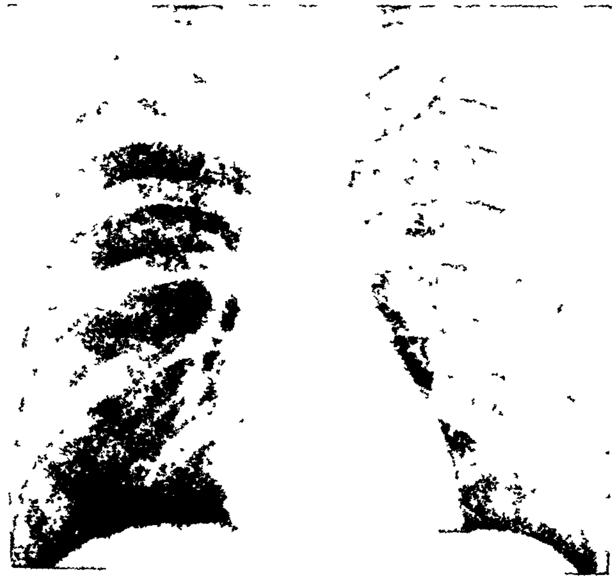

Fig 8 (case 3) —Roentgenogram made 24 days after that in fig 7 and 20 days after start of treatment with hydrocortisone and prednisone

Etiology and Pathogenesis

The diseases that occurred in these four individuals are seen to have been remarkably similar in pattern, the similarity of roentgenographic findings is equally striking, since the picture is an unusual and distinctive one. Our working hypothesis, at this point, formulated for the purpose of eventual testing, is that all four patients were afflicted with an apparently identical illness produced by one and the same etiological agent. On that assumption, all four cases are instances of bronchiolitis fibrosa obliterans, since this diagnosis has been proved by autopsy for the patients in cases 1 and 2 Moreover, since no significant pathogen has been recovered by culture from any of the patients, the initial inhalation of irritant gas by all of them must tentatively be considered the most likely cause of the illness.

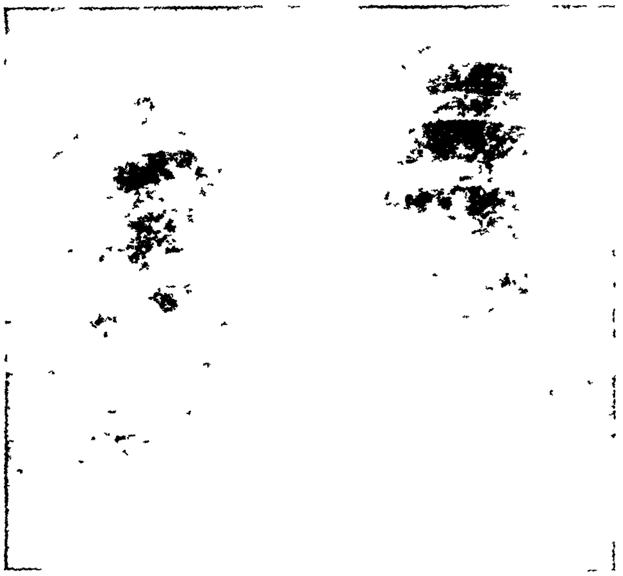

Fig 9 (case 4) —Chest roentgenogram 23 days after exposure to silage fumes and 3 days prior to administration of first dose of hydrocortisone

The next essential step in developing the above hypothesis is identification of a gas that is (1) irritating to the surface lining of the respiratory tract, (2) capable, on inhalation, of causing bronchiolitis obliterans in man, (3) demonstrated to be formed early in the course of silage fermentation, and (4) evolved by silage, under conditions that may occur in normal silo operation, in concentrations sufficient to cause pulmonary disease (including bronchiolitis) in man and animals.

Incidence and Pathogenesis of Bronchiolitis Obliterans and the Possibility of Causation by Nitrogen Dioxide—The pathological entity, bronchiolitis obliterans, is indeed rare. In a series of 70,281 autopsies performed during the 34-year period from 1919 to 1952, filed and indexed in the department of pathology, University of Minnesota Medical School, there were noted but two instances of bronchiolitis obliterans. The pathological features of the condition are very distinctive, and rigid criteria must be employed in making this diagnosis. The lungs contain innumerable, uniformly distributed lesions, which are grossly visible and palpable as firm, discrete nodules of miliary size. Microscopically, each nodule consists of a small bronchus or bronchiole filled with a rather cellular fibrinous exudate; organization of this adherent plug of fibrin by ingrowth of fibroblasts from the bronchial walls tends eventually to occlude the lumen. Bronchiolitis obliterans can be caused by inhalation of an irritant gas[4] or can occur as a complication of certain infections[5] of the lungs and bronchi. It can also be of unknown etiology. Of the known causes, gas inhalation is the most frequent and the most definitely identifiable. It has been shown clinically and experimentally that the oxides of nitrogen[6] as well as certain other toxic gases[7] are capable of producing the condition. These others include phosgene, chlorine, chloropicrin, ammonia, hydrogen chloride, and probably sulfur dioxide. Statistically, the oxides of nitrogen—ordinarily nitrogen dioxide and tetroxide, both of which are relatively stable—have been incriminated in a majority of the total documented cases of bronchiolitis obliterans caused by irritant gas.[8]

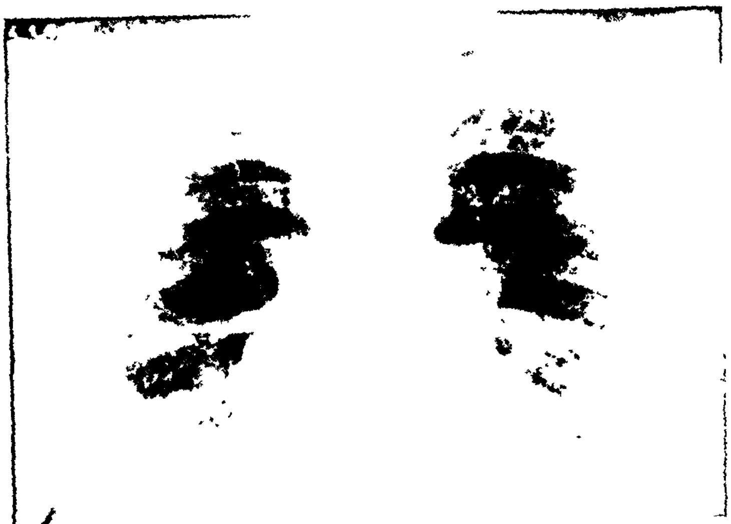

Fig. 10 (case 4).—Appearance of chest on follow-up visit three months after discharge. Patient clinically well.

Among the first gases to be considered, then, in our ch for a toxic agent that might cause silo-filler's isease, were the oxides of nitrogen. At that point in the investigation, our attention was directed to a recent review by McAdams[8a] in which one fatal case of bronchiolitis obliterans due to accidental nitrogen dioxide inhalation was reported. The circumstances of exposure in his case—explosion of several flasks containing red fuming nitric acid in a laboratory, which quickly filled with dense fumes of nitrogen dioxide—identified the gas beyond doubt. The clinical course of the victim's illness—even as to duration of each of its phases—and the observations made at autopsy were identical with the corresponding features in our cases 1 and 2.

Production of Nitrogen Dioxide in Silos.—In the agricultural literature and that of veterinary medicine, reports have been found[9] that contain acceptable evidence that nitrogen dioxide, in toxic amounts, may be given off in the process of silage fermentation. We do not know, as yet, how frequently this occurs, nor will it be possible, until analyses of air samples from silos have been conducted during the 1956 growing season, to measure directly the concentration of nitrogen dioxide attained in full-scale silos. In the meantime, however, information obtained indirectly, through analyses of gas evolved by experimental miniature silos, has been most helpful.

During our studies of this entire problem of toxic "silo gas," we have frequently sought the assistance of our colleagues in the agricultural sciences. Briggs, Jezeski, and Otis,[10] already engaged in a research project concerned with many aspects of silage-making, have in operation a number of miniature experimental silos in which they are studying the properties of different crops with respect to their potential value as silage. The temperature, moisture, nitrate content, and other factors can be altered and accurately controlled in this apparatus, and the gaseous products of silage fermentation under different conditions can be collected and analyzed. Preliminary data derived from such experiments indicate that, although actual amounts of gas vary considerably with growing conditions, a surprisingly large amount of nitrogen dioxide is formed during the first week of silage fermentation. Observed concentrations have ranged from 200 to 4,000 ppm. These figures are not directly comparable with those to be anticipated upon analysis of air samples from full-scale silos, but they indicate that silage may, without doubt, give off sufficient nitrogen dioxide to endanger men and animals. The maximum concentration of this gas in inspired air considered safe for man is 10 to 25 ppm by volume, in contrast to the far larger amounts found in the experiments mentioned above. Peterson and co-workers,[9] in 1949, found 151 ppm of this gas in a sample of silo-room air collected two days after completion of silo filling. This is the only report we have found dealing with quantitative analysis of silo air for nitrogen dioxide. Evolution of the gas begins within a few hours after the start of silo filling, reaches a maximum between one and two days later, and continues at a decreasing rate for a week or longer. No other irritant gas has thus far been noted, and there is no reasonable likelihood that any other such gas could be produced by silage in concentrations approaching toxicity for man.[10]

It may also be stated[10] that oxides of nitrogen emanating from silage are derived almost entirely from inorganic nitrates in the plant. Thus the potential concentration of gas is roughly proportional to the nitrate concentration of the silage crop. Factors known to increase plant nitrates are drought, highly nitrated soil (such as that fertilized with nitrates), and immaturity of the plant itself.[10] A trend in modern farming methods toward increasing use of organic nitrates in fertilizing mixtures and also of other commercial chemical compounds containing nitrogen appears likely to favor increasingly high nitrate concentrations in crops generally.

Other Effects of Nitrogen Dioxide upon Lungs and Bronchi.—This discussion of silo-filler's disease would be incomplete without a brief consideration of other types and degrees of damage to the respiratory system that have been shown, either clinically or experimentally, to result from inhalation of nitrogen dioxide, whether generated in a silo or elsewhere. As might be anticipated, most of the reports concerning nitrogen dioxide poisoning have dealt only with fatal cases, and of these a good number have been recorded. The excellent review of this subject published by von Oettingen[3b] in 1941 refers to at least 175 documented fatalities due to inhalation of this gas prior to that date. The victims died of acute pulmonary edema for the most part, and survived a very short time, varying from one hour or less to a maximum of about three days, after exposure. Another smaller, but distinct, group of individuals, after inhaling toxic amounts of nitrogen dioxide, are reported to have died from bronchiolitis obliterans; these deaths have occurred about three to five weeks after exposure to the gas.

Finally, it is reasonable to suppose that inhalation of nitrogen dioxide in an amount less than that necessary to cause death may produce some degree of injury to the bronchial or bronchiolar mucosa.[11] Individuals exposed to such sublethal concentrations presumably survive the experience; they may develop minor symptoms or none at all.[12] Further careful clinical study of such survivors, both human (when discovered) and also among experimental animals, will be needed to complete the picture of silo-filler's disease. We believe that the evidence, though still fragmentary, strongly suggests that a continuous spectrum, consisting of different types and degrees of bronchopulmonary injury by nitrogen dioxide, exists, and will come to be better understood. In such a spectrum, the bronchiolitis obliterans that we have noted would occupy a place among the more severe types of nitrogen dioxide poisoning resulting from silage fumes.

With this hypothesis in mind, it is of great interest to note that two additional cases of silo-fillers disease have recently been studied by Delaney and co-workers at the Mayo Clinic.[1b] One of these patients died of acute pulmonary edema 36 hours after exposure to fumes in a silo that he was in the process of filling. The second patient also inhaled fumes inside a silo that was being filled; he developed a protracted chronic illness, with extensive bilateral pulmonary infiltration. However, he was never gravely ill, and, although the appearance of the chest roentgenogram closely resembled that seen in bronchiolitis, the clinical course was far different, since this man recovered spontaneously after six to eight weeks of illness without receiving one of the corticosteroids or related compounds. It is our impression that this man had an extensive, confluent bronchopneumonia rather than a true obliterating bronchiolitis.

These cases, reported by Delaney and associates, serve to reinforce the suggestion that in silo-filler's disease we are dealing with a continuous spectrum of conditions whose manifestations are likely to differ widely and whose degree of severity depends upon (1) concentration of nitrogen dioxide inhaled and (2) duration of exposure in each individual instance. Clearly, the conditions of exposure may vary greatly, and the only essential clinical feature common to all cases is a definite history of recent inhalation of irritating fumes (nitrogen dioxide) in or near a silo.

At the present time, then, we may state that nitrogen dioxide poisoning can occur as a result of inhalation of fumes given off by fresh silage. Silo-filler's disease seems to us an appropriate and descriptive name for cases of respiratory disease clearly shown to have resulted from inhalation of nitrogen dioxide in this fashion.

Experimental work is planned that ultimately should define much more clearly the safe limit of concentration for nitrogen dioxide in inspired air. Other studies now in progress are designed to determine accurately how much time must elapse after silo filling begins before a dangerous quantity of nitrogen dioxide may accumulate; at the same time, the maximum duration of a dangerous period in silos will be determined. Finally, a simple qualitative test for nitrogen dioxide should be developed. Such a test, to be practical, must be reliable, so that the farmer who employs it may know when he can safely enter his filled silo. Furthermore, it must be sufficiently simple and rapid so that he will not be unduly delayed in his daily activities.

Prevention

Prevention of the inhalation of silo gas is simple, in theory at least. At the present time, a reasonable plan that may be suggested to farmers is as follows: 1. Allow no one to enter a silo for any purpose from the time filling begins until 7 to 10 days after it is finished. 2. Provide good ventilation about the base of the silo during this period, so that toxic gases, if they develop, will be carried away. 3. Provide fencing (or other effective means) to prevent children and animals from straying into any spaces adjoining a silo during this dangerous period. 4. Always run the blower fan before entering any silo.

The first of these rules alone, if strictly followed, would effectively prevent silo-filler's disease in man. The difficulty remains, however, that farmers generally have known for a long time that silos are dangerous during the week immediately after filling, but their actions do not reflect this knowledge. Each of the four patients in this series stated that he knew he was taking a risk when entering a recently filled silo. The fact that not one of them was deterred by the knowledge strongly suggests that their ideas about this "possible" hazard were not sufficiently definite to make them regard the danger as real. It is hoped that the concrete information embodied in this report may, by better defining the hazard, cause it to be regarded more realistically. It will be well to reemphasize here a point that is now self-evident. By outlining for farmers and silo workers the limits of a danger that they have long recognized as existing in a vague manner, we can show them how to eliminate this hazard from silo operation. Clearly, this simple means of increasing the safety of silos cannot possibly be considered as a deterrent to the making of silage. On the contrary, it should be regarded as justification for an even wider use of silage and of silos, with a serious, if limited, hazard eliminated.

Treatment

Since exposure to the higher concentrations of silo gas or nitrogen dioxide must be rapidly fatal in spite of any treatment, prevention is obviously the treatment of choice. Up to the present time, there has been very little experience with treatment of those who survive the immediate postexposure period. Although further extension and proof are required, it is deemed worthwhile to mention the apparently favorable response to corticosteroids noted in two patients (cases 3 and 4).

It may reasonably be inferred, from the cases reported here, that, if an individual inhales a toxic amount of nitrogen dioxide, diffuse nodular infiltration of the lungs is one of the likely consequences. The histories of the patients in cases 3 and 4 strongly suggest that any patient developing bronchiolitis obliterans of this type should receive full doses of hydrocortisone, prednisone, or one of the related steroids as promptly as possible. However, the diagnosis must be assured before these drugs are used, because several widespread infections, particularly miliary tuberculosis, may create a similar x-ray picture (and sometimes clinical picture as well); in such conditions, the use of steroids alone is not the most desirable form of treatment. The fact must be emphasized that this diagnosis requires an undoubted history of inhalation of irritating gas or fumes in or near a recently filled silo.

Summary and Conclusions

A newly recognized clinical entity, namely, bronchiolitis fibrosa obliterans caused by inhalation of oxides of nitrogen produced in recently filled silos, was seen in four patients. The facts leading to our conclusion regarding etiology were as follows: 1. All four patients became ill immediately upon inhaling irritating fumes in a silo or silo chute, and exposure occurred within 48 hours after filling of the silo was initiated. 2. All four presented clinical and roentgenographic findings of bronchiolitis obliterans. Two of the patients died and were found, at autopsy, to have the classic pathological lesions of the condition. 3. gen dioxide is an irritant gas and has been dem- ated to be capable of causing bronchiolitis oblit- ans upon inhalation. No other gas fulfilling these criteria has been found to emanate from silage. 4. Experimentally, nitrogen dioxide is shown to be produced early in silage fermentation; under certain conditions of soil and moisture, high concentrations—far higher than the safe limit for man—occur. We have chosen to designate as silo-filler's disease the group of pathological and clinical entities resulting from the inhalation of nitrogen dioxide in or near freshly filled silos; bronchiolitis obliterans arising from this should be regarded as one form of silo-filler's disease. Nitrogen dioxide inhalation may (in theory at least) produce a variety of bronchopulmonary conditions; the chief factor determining the type of damage is the amount of the gas inhaled. A recent report of two instances of silo-filler's disease that were widely different from our cases tends to support this conclusion. It is noted that the present trend in agriculture toward greater use of commercial chemicals containing nitrogen may tend to increase production of nitrogen dioxide from silage and hence may increase the possibility of exposure to this gas. Safety measures will prevent the inhalation of toxic silo gas, provided they are enforced. Two cases of bronchiolitis obliterans have been treated with adrenocortical steroids, with apparent success. It is important to establish a firm diagnosis (based essentially upon history of exposure) before using one of these drugs.

629 Medical Arts Bldg. (2) (Dr. Lowry).

Drs. Duane C. Olson and V. A. Schulberg, Gaylord, Minn., gave permission to report case 3. Drs. H. G. Deerhake, P. A. Connaughton, and E. Steere, Lima, Ohio, gave permission to report case 4.

Lung Abcess.—In all the annals of medical therapeutics, one cannot find a story to parallel the progress made in the treatment of pulmonary abscesses. A scant 18 years ago saw pulmonary abscesses carrying a mortality of 34 per cent and a morbidity even higher than that. It a patient were fortunate enough to survive the acute phase of his abscess, in approximately 50 per cent of the cases, he would carry a chronic draining broncho-pleural cutaneous fistula, bronchiectasis, or recurrent pulmonary hemorrhage, which would eventually cause his death. Recently Waterman and Dorm showed that the mortality rate in over 200 cases was less than 10 per cent. Even more important is the lowering of the morbidity following an acute pulmonary abscess. With the use of antibiotics, conservative draining procedures, and surgery, one is able to handle satisfactorily 80 per cent of the acute lung abscesses. The major contributing factor in this miraculous change in a very serious disease is the antibiotics that are now available for the treatment of acute pulmonary infections. In addition to this, the improved techniques for thoracic surgery have lowered the mortality and morbidity of those cases not responding to ordinary therapeutic measures. In spite of this very optimistic picture, we feel that lung abscesses still must be considered a serious disease.—W. A. Hopkins, M.D., J. Free, M.D., and M. B. Davis, M.D., The Treatment of Lung Abscess, *Journal of the Medical Association of Georgia*, February, 1956.

HYPOTHYROIDISM IN THE ADOLESCENT

Felix P. Heald, M.D., Robert P. Masland Jr., M.D., Albert E. Renold, M.D.
and
J. Roswell Gallagher, M.D., Boston

- *Important criteria for judging the status of adolescent patients with respect to the thyroid are the measurement of the uptake of radioactive iodine by the thyroid, the measurement of protein-bound iodine in the plasma, the response of both measurements to administration of the thyroid-stimulating hypophysial hormone, the basal metabolic rate, the serum cholesterol level, and the skeletal age as measured by hand-wrist roentgenograms. In one case here described, inadequate treatment of congenital cretinism had resulted, by the age of 13 years, in physical, emotional, and intellectual retardation; in a second case, myxedema resulted in pseudo-obesity and retarded skeletal growth; in a third, the skeletal age was two years less than the chronological age of 17 years, and sexual maturation had barely begun. Medication with desiccated thyroid had strikingly beneficial effects in these three. A fourth patient appeared to be overweight and had a low basal metabolic rate by surface-area standards; by height standards, however, his basal metabolic rate was found to be normal. Other criteria also showed that his thyroid status was normal. On suitable dietary management alone the changes of adolescence in this patient were completed normally without thyroid.*

Certain misconceptions regarding hypothyroidism in the adolescent are encountered so frequently that it would appear profitable to review some of the clinical and laboratory aspects of this disorder. Too often the obese adolescent is thought to be hypothyroid when actually there is no clinical or laboratory evidence to support the diagnosis. In contrast, the cold-skinned, thin, slow-maturing adolescent is rarely considered a thyroid problem, and yet a thorough diagnostic study may reveal him to have a thyroid deficiency. Furthermore, inaccuracies in computing the basal metabolic rate in the obese patient who complains of fatigue are common enough to merit further discussion. Such matters and representative cases of hypothyroidism in the adolescent are presented in this review.

Hypothyroidism in the adolescent differs from that in the adult in one important aspect. This difference is its effect on growth and development. The progress of osseous growth and development is dependent in part on adequate levels of thyroid hormone, and prolonged thyroid deficiency that retards osseous development in the growing child or adolescent obviously cannot affect in this way the adult whose growth is complete. Clinically what one sees is a retardation or a cessation of growth in a child whose growth had previously been progressing in an orderly fashion. These findings alone do not make the diagnosis of hypothyroidism but should alert the physician to a careful and thoughtful appraisal of the adolescent's growth and development.

While clinical evaluation remains the most important factor in the diagnosis of thyroid dysfunction, a number of laboratory aids have proved their usefulness. These can be classified either into measurements of thyroid hormone synthesis or into measurements of metabolic defects resulting from alterations in the levels of circulating thyroid hormone. We include in the former the measurement of the uptake of radioactive iodine (I^{131}) by the thyroid gland, the measurement of protein-bound iodine in plasma, and the response of both these indexes to the thyroid-stimulating hormone of the pituitary. Among the changes that are secondary to the decrease in circulating thyroid hormone, we measure basal metabolic rate, serum cholesterol level, and bone age.

The determination of the basal metabolic rate merits some discussion. The basal metabolic rate is still to be considered a useful measurement, but its many limitations have to be kept in mind when interpreting the results. It is not a direct measure of thyroid function but a measure of the resting metabolic state. Technical errors are frequent but relatively easy to detect: endogenous interferences resulting in failure to obtain a true basal metabolic level can usually be established by careful questioning and observation of the patient. The chief and least frequently recognized error arises in the calculation of the metabolic rate of obese adolescents.

That formulas that include weight produce erroneous results in those patients is easily understood when one realizes that up to 30% or more of total body weight may consist of fat, which we know to have a low metabolic activity. In fact, basal metabolism seems to be closely related to fat-free active tissue mass.[1] If this is the case, this, rather than a formula that includes total weight, would be a more accurate basis for determining basal metabolism. Unfortunately, however, at the present time the measurement of fat-free tissue is impractical for routine use.

When the patient's fat is not taken into consideration in the calculation of the basal metabolic rate, an erroneously low figure for basal metabolic rate will be obtained. This error is especially likely when surface area standards are used[2]; the reason for this is that as weight increases the surface area does not increase in proportion to the increase in body tissue mass.[1] In our experience it is helpful to calculate the basal metabolic rate of overweight adolescents on the basis of standard height tables.[2] It is to be remembered that the basal metabolic rates calculated in this manner tend to be a little high, but they certainly cor-

Read before the Ninth Clinical Meeting of the American Medical Association, Boston, Nov. 30, 1955.

relate more closely with one's clinical impression and with other laboratory tests than do the basal metabolic rates of young obese patients calculated on surface area standards.

From the foregoing, it is clear that the basal metabolic rate of an obese adolescent should be carefully evaluated and appropriately calculated. If it is low, careful appraisal of its method of calculation and of the patient's history and physical examination should be made. Subsequently, any lingering doubts about thyroid deficiency can usually be resolved by such measurements of thyroid function as I^{131} uptake and protein-bound iodine level. As a screening method, determination of the protein-bound iodine level seems to be the most satisfactory means of assaying thyroid function.[1] This test is accurate and reproducible and represents a relatively direct measure of circulating levels of thyroid hormone. The possibility of its invalidation by previous iodine therapy should, however, be kept in mind.

The evaluation of skeletal age by means of hand-wrist roentgenograms is a valuable procedure in the study of patients presenting growth problems.[1] Lowered body metabolism due to true thyroid deficiency directly affects and retards skeletal growth, and if the bone age is equal to or advanced beyond the chronological age, there is little reason to suspect thyroid deficiency. However, retarded skeletal development may represent a normal variation in growth, may be evidence of hypothyroidism, or may accompany pathological processes other than hypothyroidism.

Report of Cases

CASE 1.—A patient had congenital hypothyroidism or cretinism that had been inadequately treated over a period of many years. The most striking findings were the generalized retardation of all osseous development, poor peripheral circulation, and failure of certain body structures to differentiate. The patient came to the adolescent unit of the Children's Hospital at age 13 because of physical, emotional, and intellectual retardation. Her present illness dated from infancy. Her delivery had been normal, but in the first six months of life she was slow, sleepy, and a poor eater. Her weight gain was slow and food intake poor. When she was 17 months of age, a physician said she had an incurable glandular disease and prescribed two small white pills after each meal. This medication was continued for years, but its administration was sporadic and according to the mother's or the child's whims. The child's growth and development continued to be slow and her appetite poor until the time she was seen in our unit.

The patient's height was 43 in. (109.2 cm.) and her weight 68 lb. 12 oz. (31.1 kg.). Her blood pressure was 80/60 mm. Hg, pulse rate 60 per minute, and respiration 24 per minute. She was a very small and "obese" child, with a full face and periorbital edema. Her olive skin was extremely dry and cool throughout and her hair abundant but coarse. All but eight of her teeth were primary ones. Her thyroid was not palpable. Fat pads of moderate size above the clavicles and a hump at the back of the neck were noted. The abdomen was protuberant, and an umbilical hernia was present. There was pitting edema of the lower extremities. Hematological studies showed moderate normochromic anemia. The serum cholesterol level was 410 mg. per 100 cc. A hand-wrist x-ray demonstrated a bone age of 7 years, which was six years behind her chronological age. A gradually increased dosage of thyroid extract was prescribed. After a period of adequate therapy, the patient became euthyroid, and gradually her physical status improved.

CASE 2.—This patient presents a classic picture of myxedema, the end-result of prolonged hormone deprivation. Although she appeared fat, the important fact is that she was not truly obese. Her pseudo-obesity is of the type that is often taken for true obesity and has led to the confusion of hypothyroidism with obesity. This patient was brought to our unit at age 12 years and 6 months because she had changed from a very slender child to a very fat one during the previous 12 months. Two years prior to admission she had had abdominal pain for a two-week period. Gastrointestinal roentgenograms at that tim were reported as showing her small intestine "almost closed." She was given a low-residue diet at that time, but her intermittent abdominal pain persisted. Formerly a sound sleeper she began to wake easily at night, and, although she had had good appetite, it became poor. Her mother thought that th child's hair was becoming coarser than it used to be and sai that her general activity had become increasingly sluggish Frequent bulky stools had been noted in recent months. A her first visit, we found the patient to be a pleasant, but lethargic, plump child. She said she had noticed loss of appeti and loss of energy during the previous year.

Her weight was 102 lb. (46.3 kg.) and her height 53 i (134.6 cm.). Her skin was dry. The thyroid was soft but n enlarged. Her abdomen was protuberant. The reflexes we sluggish but equal. Her bone age was two years less than h chronological age. She showed a mild normochromic anemi The serum cholesterol level was 180 mg. per 100 cc., and t protein-bound iodine was below a measurable amount. Th patient was considered to have acquired myxedema and w given 30 mg. of thyroid extract daily. Her most striking respon to thyroid extract was the resumption of her growth. She also ha an initial weight loss followed by a weight gain, and her skin an peripheral circulation changed to a normal state.

CASE 3.—It is the obese adolescent whom the physician most frequently asked to evaluate, and the basal metabol rates should be calculated with due regard for the effect of e cessive fat on the result. This patient had gained weight rapid during his 13th year. His mother said that for the previous months he had been overweight and that he was still gaini weight. She explained that she herself was taking thyroid e tract. She believed that her son should have a metabolism te and that he needed thyroid extract.

On his first visit the patient was 13 years and 8 months age. His height was 66.5 in. (168.9 cm.) and his weight 1 lb. (57.6 kg.). He seemed to be an alert, healthy, well-adjust young boy whose appearance was typical of a moderately f adolescent. His hair was not coarse; his eyebrows were not thi The palms were moist, and his extremities were warm. The was nothing sluggish about his behavior, and his success in bo his school work and his outside activities was good. His bas metabolic rate calculated on surface area standards was −15 but when calculated on height standards it was −2%.

The patient appeared to be a perfectly normal young ad lescent. It was suggested that he restrict himself from suc fattening foods as gravy, mayonnaise, and cream and fri foods but that he continue to eat a diet relatively high in pr tein and calories. He was told that his growth and developme were perfectly normal and that in all probability as he gre taller he would thin out, but that processes of growth and d velopment could not be predicted with absolute certainty an that it would be well for him to be seen at three-month inte vals for evaluation of his progress. It was believed that th recommendation would not only reassure the boy but also mak it less likely that the mother would take him from doctor t doctor until "hormone injections" or thyroid extract were pre scribed or until he would reach the point where he would b really convinced that he was abnormal. Twenty-four month later, when he was 15 years and 8 months of age, his heigh was 67 in. (170.2 cm.) and his weight 132 lb. (59.9 kg.). H had completely lost the chubby appearance of a boy in earl adolescence and had acquired the secondary sexual characteristics of an adult male.

CASE 4.—At age 17, a patient came into our unit because of headaches, easy fatigability, fainting episodes, and slow maturation. Six months prior to admission he had noticed that his appetite was poor, that sports fatigued him quickly, and that he required more sleep than usual. Three months previously he began to have weak spells and fainted on several occasions. The fact that his younger sister was 4 in. taller than he was irritated him. He was a very pleasant, responsive boy who was puzzled by his symptoms and disgruntled with his small stature. He was 60.75 in. (154.3 cm.) tall and weighed 100 lb. (45.4 kg.) His pulse rate was 60 and his blood pressure 120/80 mm. Hg His hair was brittle and coarse, and his skin was cool and dry.

The thyroid was not palpable. Sexual maturation had barely begun. The laboratory results confirmed the clinical impression of hypothyroidism. The bone age was two years less than his chronological age of 17 years. The serum cholesterol level was 245 mg. per 100 cc., the protein-bound iodine level was 2.4 mcg per 100 cc., and the basal metabolic rate was –33%.

Administration of desiccated thyroid extract was begun, and the amount given was gradually increased. His easy fatigability diminished, and his alertness and responsiveness and appetite increased. His growth progressed, and his skin became warm and was not dry. In our experience this form of hypothyroidism is often unrecognized. It was not clear whether this boy had acquired hypothyroidism or whether he had a transient depression of thyroid function, but it is a fact that during thyroid extract therapy his physical status made a striking improvement. It should be emphasized that very few thin, late-maturing adolescents are hypothyroid, but this possibility should be kept in mind.

Comment

The first two patients illustrate situations classically associated with hypothyroidism and without essential differences in the adolescent age group. The fact that patients presenting similar findings are occasionally seen in a practice confined to the adolescent age group indicates the need to be on the lookout for adolescents whose hypothyroidism has had inadequate treatment in earlier years or who suffer from classic myxedema.

The third and fourth case reports illustrate the situations encountered when hypothyroidism is considered in the differential diagnosis of the obese or slow-maturing adolescent. The opinion that a fat, sluggish, fatigued adolescent who has a low basal metabolic rate has hypothyroidism still persists. However, when these young people are more carefully studied, little is found to suggest that thyroid deficiency exists. The history obtained from these obese adolescents is that of gradual accumulation of subcutaneous fat. Frequently this is associated with complaints of sluggishness or fatigue. The dietary history is invariably one of a normal to prodigious appetite, never an impaired one. A normal to prodigious appetite is incompatible with the diagnosis of true thyroid deficiency. Furthermore, the growth of these young persons, as determined by history, physical examination, or bone age, is normal. This militates against thyroid deficiency, since retarded growth is one of the outstanding features of hypothyroidism in adolescence. The physical examination also fails to divulge any of the classic features of hypothyroidism. The skin is warm, the palms are moist, the complexion is ruddy, the hair is not coarse, and there is no thinning of the outer eyebrows. Pulse rate and pulse pressure are found to be in the normal range, and subcutaneous tissue is firm in contrast to the loose, thick turgid skin seen in myxedema.

Case 3 illustrates the need to keep in mind that many young people tend to put on subcutaneous fat during early adolescence and that this in itself is not suggestive of hypothyroidism. In particular, great care should be used in interpreting basal metabolic rates in these patients. Desiccated thyroid extract should never be given on the basis of a single low metabolic rate, a low determination should only provoke a more critical evaluation of the entire clinical picture. Further laboratory investigation may be indicated if reappraisal still leaves the question of hypothyroidism in doubt.

On the other hand, a thin, dry and cold skinned, irritable adolescent (case 4) is often not given the benefit of a therapeutic trial with thyroid extract because the presence of hypothyroidism is not suspected. The majority of thin, late-maturing patients will be found to represent only normal variations in growth and development, but a small percentage will be found to have such findings and signs as slow growth, poor appetite, intolerance to cold, short stature with minimal subcutaneous tissue, cold, dry skin and dry palms, retarded sexual maturation, thin eyebrows, a bone age two to three years behind chronological age, a low protein-bound iodine level, and an elevated serum cholesterol level. This form of acquired hypothyroidism is not the classic picture as described in the literature, but various authors recognize this syndrome as a stage in the development of hypothyroidism.[5]

The primary purpose in the treatment of uncomplicated hypothyroidism is to restore the adolescent to a euthyroid state as safely and rapidly as possible. The dose must be adequate to reverse the abnormal physiological functions and to assure resumption of osseous growth. Talbot and co-workers[6] recommend a dosage of 60 to 90 mg. of desiccated thyroid (U. S. P.) per square meter of body surface. Full dosage should not be given at the onset. It is well to begin with one-quarter of the calculated full daily dose and then to increase the amount at two-week intervals, provided symptoms of overdosage do not occur. In adolescence, where maintenance of growth is important, the maximum dose of thyroid that can be tolerated without symptoms of nervousness, insomnia, diarrhea, and weight loss is the correct amount for that patient. This maximum tolerated dose makes possible the resumption of growth and the full utilization of the patient's inherent growth potential.

Summary

Certain misconceptions regarding hypothyroidism in the adolescent are frequently encountered. Features of the growth and developmental history and of dietary pattern often give the physician valuable clues for an evaluation of thyroid status. Obesity and hypothyroidism in the adolescent are often mistakenly associated. The thin, late-maturing, cold-skinned adolescent, who is at times not recognized as being hypothyroid, may often be so.

UROLOGIC PROBLEMS IN POSTPOLIOMYELITIC PATIENTS IN RESPIRATORS

WITH SPECIAL EMPHASIS ON MAJOR UROLOGY SURGERY

John J. O'Connor Jr., M.D.
and
Lewis Wiener, M.D., New York

• Urinary calculi occurring in postpoliomyelitic patients in respirators present important problems of prevention and treatment. No dependable methods of prevention have been developed; methods of treatment may be classified as either conservative or surgical. The possibilities of conservative treatment are illustrated in the case of a 9-year-old girl with bilateral obstruction by ureteral calculi; after cystoscopy and bilateral ureteral catheterization, the calculi passed down the ureters over a period of three weeks and were eventually passed by the urethra with minimal symptoms. Details are given of two other cases in which surgical treatment became necessary. Major urologic surgery in the renal fossa was performed successfully seven times in five patients. The lateral nephrectomy position was used; it was formerly thought that these patients would not tolerate this position. Resection of the 12th rib facilitated the approach to the kidney. Since much of the patient's muscle is replaced by fibrous tissue, dissection may be hard and hemostasis requires special attention. The use of the endotracheal tube during anesthesia, of special forms of respirators, of induction with thiopental given intravenously, of antibiotics, and of the nasogastric tube to prevent gastric dilatation, all contributed to the success of the surgery, which these patients tolerated surprisingly well.

In the past decade, the advances made in the rehabilitation of postpoliomyelitic patients in respirators have markedly changed the prognosis for such patients. Where these people were formerly confined for life in the "iron lung," today, with the advent of new knowledge concerning pulmonary physiology, respiration techniques, chest respirators, and rocking beds, many of these unfortunate victims of poliomyelitis can be returned to a more nearly normal life. In view of these advances, it is well to reconsider the urologic aspects of their disease and, if possible, to attempt to keep abreast of the ground gained in the other fields of rehabilitation.

The primary urologic problem is urinary tract calculus formation, probably secondary to hypercalciuria, which is directly proportional to the extent of residual paralysis.[1] Most calculi consist of calcium in various combinations with phosphate, ammonia, carbonate, and magnesium. It is well to note that neurogenic bladder dysfunction is not present in the type of patient under discussion, except for temporary bladder atonicity during the acute phase of the illness. The problem may be divided into two major phases: (1) the prevention of calculi by medical means, and (2) the management of calculi already present. The former has been aimed mainly at the reduction of hypercalciuria. Among the various methods may be mentioned (1) postural renal drainage,[2] (2) mobilization of the patient by rocking beds and tilt boards, (3) hormonal therapy with testosterone alone or in combination with estrogen,[3] (4) high fluid intake, (5) low-calcium diet, (6) Shorr regimen (administration of basic aluminum carbonate [Basaljel] or aluminum hydrochloride [Amphojel] to diminish intestinal absorption of phosphate), (7) parenteral administration of hyaluronidase to increase the amount of protective colloids in the urine.[4] (8) local instillation of G (Suby's) solution in an attempt to dissolve calculi,[5] (9) acidification of the urine with ammonium chloride and other acidifying drugs, (10) administration of antibiotics for control of urinary tract infection, and, most recently, (11) the use of orally given salicylates to increase urinary glucuronides.[6] To date, all of these procedures, with the exception of salicylate therapy, which as yet has not had adequate clinical trial, have proved disappointing in the prevention of new or recurrent calculus formation.

The second phase of the problem, the management of stones already present, may be further subdivided under two headings: (1) conservative therapy and (2) surgical therapy. The conservative approach to the treatment of calculi, which would include watchful waiting, cystoscopic procedures, forcing of fluids, and use of antispasmodics such as propantheline (Pro-Banthine) bromide, is obviously the treatment of choice in such cases. In considering the usual indications for cystoscopy and ureteral catheterization for drainage, one must take into account the important fact that even large ureteral calculi will pass spontaneously with unusual ease in these patients. However, as in the usual urologic practice, there are cases where conservative therapy fails and we must resort to surgery in order to preserve kidneys and even lives. In the past, any major surgical procedure, and, in particular, renal surgery, was frequently avoided because of the supposedly prohibitive operative risk and poor survival rate in patients confined to the "iron lung."[7] Recently, in view of the progress in rehabilitation of these patients and the improved techniques in anesthesiology and pulmonary physiology, it was deemed advisable to reevaluate the operative risk in patients in respirators. Employing the usual indications for operative interference and working closely with the pulmonary physiologist and anesthetist, we performed major urologic surgery seven times in five patients.

Consultant in urology (Dr. O'Connor) and resident in rehabilitation (Dr. Wiener), New York Regional Respirator and Rehabilitation Center, Goldwater Memorial Hospital.

Read before the Section on Urology at the 190th Annual Meeting of the Medical Society of New Jersey, Atlantic City, N. J., May 16, 1956. This paper has been released for publication here through the courtesy of *The Journal of the Medical Society of New Jersey*.

At the time of writing, there are 28 paralyzed postpoliomyelitic patients at the New York Regional Respirator and Rehabilitation Center at Goldwater Memorial Hospital in New York City. All were confined to respirators on admission, and nearly all had had their disease for more than one year. Involvement in all cases is high spinal; no patient has bulbar involvement. Many, through rehabilitation, are able to use rocking beds and wheel chairs. All 28 patients have hypercalciuria, with a constant 2+ to 4+ reaction to the Sulkowitch test. Ten (35%) have had urinary tract calculi, two of which were of the staghorn type. All patients with calculi had significant pyuria and varying degrees of hematuria. Five patients underwent seven major urologic procedures in the year prior to writing. Two patients had bilateral renal surgery. Two had had drainage by a ureteral catheter. The remainder had purely conservative treatment.

Report of Cases

Case 1.—A 9-year-old female developed poliomyelitis in October, 1954. On admission to the center, she had pyuria, alkaline urine with a specific gravity of 1.008, and a 2+ reaction to the Sulkowitch test. A roentgenogram of the abdomen was negative for calculi. In December, 1955, the patient developed bilateral flank pain, a temperature of 105 F (40.6 C), and shock. A blood culture was positive for Proteus vulgaris. The blood urea nitrogen level, which previously had been normal, rose to 36.5 mg. per 100 cc. A roentgenogram showed bilateral midureteral calculi, one to each side, both quite large, measuring roughly 1 by 0.5 by 0.5 cm. Cystoscopy and bilateral ureteral catheterization were done without anesthetization. A cloudy drip appeared from both sides. Catheters were left in situ for drainage. Because of shock and the grave condition of the patient, surgery was deferred. The patient was placed in a respirator tank, and antibiotics were given. In two days, the temperature was normal and the blood urea nitrogen level was down to 15 mg. per 100 cc. A roentgenogram showed catheters in situ and both stones back in the renal pelves. After two days the catheters were removed. Subsequent roentgenograms showed that the calculi passed down the ureters over a period of three weeks. They were eventually passed by the urethra, with minimal symptoms.

This case demonstrates how much can be accomplished by conservative therapy, as by simple catheter drainage of kidneys. It also demonstrates that unusually large stones can pass spontaneously in postpoliomyelitic patients. It is interesting to note that, although this patient was placed on continuous salicylate therapy immediately after the acute episode, she has since developed new caliceal calcifications bilaterally. The patient has been asymptomatic since passage of the ureteral stones.

Case 2.—A 38-year-old male developed poliomyelitis in November, 1949, with resultant quadriplegia. He has been confined to a tank respirator since onset of illness. In 1952, x-ray examination of his abdomen showed multiple bilateral renal calculi. In July, 1954, the patient developed bilateral back pain, fever, pyuria, and a blood urea nitrogen level of 28 mg. per 100 cc. He was treated successfully with oxytetracycline (Terramycin). When he was admitted to the center in January, 1955, urinalysis showed that his urine had a specific gravity of 1.002 to 1.010; he had pyuria, a 3+ reaction to the Sulkowitch test, and occasional hematuria. In July, 1955, he developed tenderness of the left costovertebral angle, oliguria, and hematuria. An intravenous urogram showed multiple calculi in an atrophic, nonfunctioning right kidney and also two large calculi in the upper ureter on the left and several smaller stones in a hydronephrotic left renal pelvis. Phenolsulfonphthalein excretion was 20% in one hour. The blood urea nitrogen level was 15 mg. per 100 cc. The white blood cell count gradually rose, and the patient began to run a low-grade fever. The blood urea nitrogen level increased to 19.5 mg. per 100 cc., and the patient began to show signs of early uremia. In October, 1955, with the patient in the lateral nephrectomy position and under endotracheal anesthesia, the left kidney was exposed through the usual loin incision after resection of the 12th rib. The ureteral stones were removed through a high ureterotomy incision. A large stone was removed from an intrarenal pelvis by the insertion of a Randall stone forceps[8] via the ureterotomy incision. Six smaller stones were recovered after forceful irrigation of the calices with an antrum-irrigating nozzle. A film taken postoperatively showed no calculi remaining in the left renal area. Immediately postoperatively, the patient was placed in a tank respirator. His postoperative course was uneventful save for acute gastric dilatation on the third day, which was easily controlled with suction via a nasogastric tube. The blood urea nitrogen level on the fifth postoperative day was 11.5 mg. per 100 cc. Extensive ecchymosis was noted in the skin, but the wound healed promptly by primary intention. The calculi consisted of calcium and magnesium phosphate. There has been no recurrence of stones on the left side up the time of writing.

This case demonstrates several important points concerning the surgical treatment of patients dependent on respirators. First, it is seen that these patients can be successfully operated on. Second, the lateral position is surprisingly well tolerated by these patients when they are under endotracheal anesthesia. Because of the paralysis of the thoracic muscles, the ribs take a more vertical direction, and in order to enter the renal fossa it was found necessary to resect the 12th rib in all patients in whom the renal fossa was entered. The complication of gastric dilatation is a very real and very frequent danger in patients confined to respirators and is, in fact, a not uncommon cause of death in these patients.[7] Fortunately, prompt recognition and treatment by nasogastric suction relieve this often distressing complication. The presence of a trained anesthetist during surgery and of a trained respirator team during the postoperative period is mandatory for successful completion of surgical treatment. This patient is now employed full time by a national foundation in his capacity as a lawyer. In short, removal of the calculi and reversal of uremia have returned him to a useful existence.

Case 3.—A 26-year-old female contracted poliomyelitis in August, 1953. Because of respiratory paralysis, tracheotomy was performed and she was then placed in a tank respirator. Studies at another hospital revealed quadriplegia and a moderate hypertension. Study of the urine showed 2+ albumin, pyuria, hematuria, and a positive culture for P. vulgaris. An intravenous pyelogram showed a nonfunctioning right kidney, two calculi in the lower right ureter, and several stones of fairly large size in the left renal pelvis. Cystoscopy was done repeatedly for removal of bladder calculi apparently passed from the left kidney. Ureteral catheters passed beyond stones in the right ureter obtained no urine. In July, 1955, the patient was transferred to this center for further rehabilitation. Her condition improved to the point where she could use the chest respirator and for short periods could be placed in the rocking bed. However, in September, 1955, the patient developed pain in the left flank, hematuria, and fever. An intravenous pyelogram showed a nonfunctioning right kidney with two lower right ureteral calculi, as noted before. On the left there were several large pelvic stones and one smaller stone in the midureter. Ureteral catheters were passed to both kidneys; no urine appeared on the right, and a clear drip was noted from the left. Within a week, the stone in the left ureter passed spontaneously. We felt that, with several calculi on the left poised as potential ureteral obstructions, every attempt should be made to restore the function of the right kidney. A trial of ureteral catheter drainage from the right kidney produced only 10 cc. in 24 hours. A retrograde pyelogram showed moderate hydronephrosis.

It was decided that, in spite of poor return of urine, the risk was justified in an attempt to restore function by removal of the calculi. It would also reveal to us whether or not a kidney totally blocked for a year could function again after removal of the obstruction. In November, 1955, therefore, a right low ureterolithotomy was done through a Gibson incision,[9] with the patient under endotracheal anesthesia. The ureter was markedly bound down with a periureteral scar, and the stones were removed after considerable and difficult dissection during which several tears were made in the peritoneum. A no. 10 red rubber catheter was passed retrograde to the kidney through the ureterotomy, and frank heavy pus was evacuated. In view of the pyonephrosis and the danger of leakage of pus into the peritoneal cavity, the decision was made at the operating table to remove the kidney. The patient was placed in the lateral nephrectomy position, and, through the usual loin incision, with resection of the 12th rib, a rather difficult subcapsular nephrectomy was performed. The patient made an uneventful surgical recovery, both wounds being healed within one week. The patient did well until April, 1956, at which time she developed costovertebral pain on the left, fever, and a rise of blood urea nitrogen level to 31 mg. per 100 cc. A roentgenogram revealed a large calculus in the upper left ureter and another in the lower calix. A no. 6 ureteral catheter passed easily into the left pelvis, from which approximately 50 cc. of very thick purulent material was aspirated. The catheter was left *in situ* and irrigated every four hours with 15 cc. of streptokinase-streptodornase solution. The urine was nearly clear within 24 hours, and the blood urea nitrogen level returned to normal. Four days later a routine high ureterolithotomy was done through a loin incision, with the patient in the lateral position. The stone in the lower calix was obtained by flushing of the lower calix with an antral irrigator inserted through the ureteral incision. The stone was dislodged into the pelvis and easily removed with a stone forceps. The patient made an uneventful recovery.

This case illustrates two important factors. If the patient had had earlier removal of the low-lying calculi in the right ureter, kidney function might well have been preserved on that side. As it was, the delay of over a year eventually led to complete loss of right kidney function. It is further demonstrated that this type of patient can be subjected to rather extensive surgery and yet do surprisingly well. The use of the antral irrigator has proved to be a great time-saving device on several occasions. By this maneuver we have dislodged many caliceal calculi without extensive probing or nephrotomy, which is not the most desirable procedure in the case of a unilateral kidney.

The remaining three patients had four major procedures; one had a pyelolithotomy and later a nephrotomy on the opposite side, and the other two each had a pyelolithotomy. All operations were done with the patient under endotracheal anesthesia and in the lateral position, with resection of the 12th rib done as a necessary adjunct to good exposure. All did well during surgery and all went on to full surgical recovery.

Comment

It is not within the scope of this paper to discuss in detail the problems involved in the medical approach to the prevention of calculus formation. Suffice it to say that, up until the present time, no really satisfactory method, chemical or physical, has yet been brought forward. Salicylate therapy is as yet too new for any definite statement to be made.

The practical problem at hand, then, remains the management of calculi already present and the prevention, as far as possible, of stone formation. Spontaneous passage of large ureteral calculi is a rather common occurrence in these patients. Many cases of temporary obstruction can be easily handled by ureteral catheter drainage for short periods of time. However, not infrequently surgical intervention may become necessary to effect relief, and, in view of the fact that pyonephrosis and cortical abscesses secondary to calculi are an important cause of death in this group of patients,[7] the problem is of the first magnitude. The only previous report of urologic surgery in patients in respirators that we could find was that of Brady and Wilson, in 1948.[2] At that time, they presented two instances of major urologic surgery. The first was a low ureterolithotomy through the Gibson incision, with mask anesthesia and manual artificial respiration; the wound healed in two months. The second was a nephrectomy through the anterior transperitoneal approach for calculi, again with mask anesthesia and manual artificial respiration. The anterior approach was used because the authors did not believe that the patient would tolerate the lateral nephrectomy position. This wound closed in six weeks. The seven operations herein presented were all done with the patient in the lateral position and under endotracheal anesthesia. All patients did well during and after surgery, with healing in each case by primary intention. The two great new advantages are, of course, endotracheal anesthesia, which permits controlled breathing, and antibiotics.

The specific problems encountered may be divided into three types: anesthetic, surgical, and postoperative.

Anesthetic Problems.—The induction of anesthesia depended upon the stage of rehabilitation. If the patient was in a respirator, an ingenious plastic bell was fitted over the head support, enclosing only the patient's head. Within this bell or dome, rhythmic increase and decrease of pressure was maintained to "breathe" the patient. In the meantime, an intravenous infusion was started and induction was done with thiopental (Pentothal) sodium. Once the patient was asleep, the bell was removed and an endotracheal tube inserted and attached to the gas machine. The patient was then moved to the operating table and positioned. If the patient was in a chest respirator, induction was instituted with thiopental, the endotracheal tube was inserted, the chestpiece was removed, and the patient was transferred to the operating table. For patients in rocking beds or wheel chairs, induction was accomplished with the chest respirator and thiopental.

Surgical Problems.—The major problem at surgery was bleeding, particularly while the muscles were being incised. It was noted that much of the muscle in these patients was replaced by fibrous tissue, so that the contraction of smaller blood vessels was prevented. Hemostasis is meticulous and time consuming. As expected, there was in all cases marked periureteral and perirenal scarring that on occasion made for difficult dissection.

Postoperative Problems.—Two major problems were present in the postoperative period. The first and most serious was tracheobronchial mucus formation, which could lead to atelectasis and bronchopneumonia, the commonest cause of death in patients in respirators.[7] This hazard was combated by several means. All patients were placed in tank respirators postoperatively; intermittent coughing was produced by means of a cough machine, deep breathing was performed by the respirator, tracheal suction was done as necessary, and humidification was accomplished if indicated. The second danger lay in acute gastric dilatation, which is a common occurrence and not infrequently fatal. Treatment was with suction via a nasogastric tube. Antibiotics were liberally given in the postoperative period. The urine output was maintained at 1.5 liters per day at least.

Summary

The primary urologic problem in postpoliomyelitic patients in respirators is urinary tract calculus formation. The problem has two phases: the prevention of calculi by medical means and the treatment of calculi already present by either conservative or surgical means. Major urologic surgery in the renal fossa has been performed seven times in five patients who were in the lateral position and under endotracheal anesthesia. All patients did well during surgery and in the postoperative period. With the proper indications, and with the urologist working in close cooperation with the anesthesiologists and pulmonary specialists, postpoliomyelitic patients in respirators can undergo major urologic surgery successfully.

POPULATION SCREENING FOR UTERINE CANCER BY VAGINAL CYTOLOGY

PRELIMINARY SUMMARY OF RESULTS OF FIRST EXAMINATION OF 108,000 WOMEN AND SECOND TESTING OF 33,000 WOMEN

Cyrus C. Erickson, M.D., Bennett E. Everett Jr., M.D., Lloyd M. Graves, M.D., Raymond F. Kaiser, M.D.

• *The method of exfoliative cytology introduced by Papanicolaou and Traut was applied to material obtained by vaginal aspiration from 108,000 women in Shelby County (including Memphis), Tennessee, for the purpose of detecting various types and stages of carcinoma. The preparations for this large-scale screening program necessarily included an extensive educational campaign and required the cooperation of many organizations. Results were reported to the physician who obtained the smears; he in turn informed the woman tested. A woman whose smears showed suspicious cells was advised to have this examination repeated and to have tissue studies in addition. Of the 108,000 women, 33,000 were examined a second time and more than 8,000 a third time.*

The program so far has resulted in the finding of 393 intraepithelial carcinomas, of which 353 had not been suspected, and 373 invasive uterine cancers, of which 112 had not been suspected. The program is also expected to yield new data on etiological factors and on the relation of preinvasive to intraepithelial lesions.

Recent reports indicate that certain factors such as inflammation, endocrine disorders, and pregnancy appear to influence the frequency of uterine cancer, particularly cervical cancer.[1] However, until there is available more specific knowledge concerning the cause or causes of uterine cancer that can be applied as a means for prevention, the direction of efforts toward the early detection, diagnosis, and treatment of this disease while it is still in localized or incipient stages appears to offer the greatest hope for reducing mortality. It is well known that such cancers, when detected in early or localized stages, can be cured. Some cancers, particularly those on or near the surface of the body, are readily detected because of their mass. Others in their early development grow deep to outer cell layers and do not reveal their presence by their mass or by surface change. The latter can be recognized grossly only when they reach the stage where there are apparent surface changes or when symptoms develop. It is well known that this is especially true of cancer of the cervix uteri and that, in its early stages, cancer of this organ is not usually evidenced by gross surface change or clinical symptoms. Prior to the development of techniques of exfoliative cytology, biopsies revealed these early lesions only incidentally or occasionally when gross findings or symptoms were present that led to a suspicion of cancer.

The method of exfoliative cytology introduced by Papanicolaou and Traut[2] in 1943 offered a simple means of finding cellular evidence of cancer in the genital tract. The use of this technique also sharpened the focus on the lesion known as intraepithelial (in

---

From the University of Tennessee and the National Cancer Institute.

situ) carcinoma of the cervix by detecting this condition in many women who had no signs or symtoms of disease. This brought further attention to the possibility of finding localized disease when it was not recognizable by other procedures. The usefulness of exfoliative cytology as an aid in the diagnosis of cancer of the uterus, bronchus, and stomach has been well attested. It is clear that this method is especially adaptable for examination of the female genital tract because of the simplicity of taking specimens and the ease of follow-up study by biopsy.

It appeared to us that exfoliative cytology might be put to greater use than simply as a diagnostic aid for women with symptoms. Earlier studies of screening by this method of smaller groups of apparently unselected women have had both favorable and unfavorable results.[3] It was our belief that, if this method were applied effectively to a large, unselected group of women, it would be possible to detect cancer at the curable phase and also to learn much about the relationship of so-called intraepithelial carcinoma to cancer. If this method could be used to find preclinical, localized cancer in large groups of apparently well women, the technique could be applied as a screening procedure; the majority of women in such a population could thus be assured that there was no evidence of uterine cancer, while the small group that should be further evaluated by another smear examination and by tissue study for the purpose of definitive diagnosis could be determined. It was essential, as in any test for cancer, that the method should not miss many women with cancer. If many women were incorrectly told that they showed no evidence of cancer, the false reports and false security resulting could bring this approach into disrepute. It was not considered essential, however, for the results of such a screening procedure to be positive only when cancer is present, for women whose smears are found to be suspicious by cytological tests can be studied adequately by cervical biopsy, endocervical curettage, cold knife conization, or diagnostic endometrial curettage as indicated. The group of false-positive results, however, should be kept reasonably small.

Method of Study

With the above facts in mind, we set out to determine how the methods of exfoliative cytology could be applied to the women of Memphis and Shelby County. We had two objectives: to determine the feasibility of using exfoliative cytology as a method for the early detection of cancer and intraepithelial carcinoma and to study the natural history of cancer of the cervix. At the beginning of this study, there were 165,000 women over 20 years of age in this area. It is estimated that this number is now closer to 200,000. We proposed to examine as many of these women as possible by a single vaginal examination and to reexamine them at least three times at intervals of at least a year. In all women whose smears showed suspicious cells, tissue studies were advised as a yardstick to measure the efficiency of the cytological method and as a basis for definitive pathological diagnosis.

The project is a joint effort of the University of Tennessee and the National Cancer Institute. As the first step, the approval and cooperation of the Memphis and Shelby County Medical Society and the participation of the Memphis and Shelby County Health Department were obtained. The local units of the American Cancer Society have also been sponsors. The cooperation of these agencies and especially the increasingly enthusiastic participation of physicians of this area have been essential in carrying out the study.

The cytological laboratory was organized to process and prepare reports on approximately 1,000 to 1,800 smears per week, as described previously by Dunn and Sprunt.[4] Vaginal aspiration was chosen as the method of obtaining the smear rather than one of the cervical procedures because of the accessibility and ease of obtaining specimens, simplicity of this technique, and its applicability to mass screening. The use of scraper, aspirator, swab, or sponge for the purpose of removing cell specimens from the cervix would require insertion of a speculum. The arguments in favor of the latter approach were that this would also require and permit visualization of the cervix by the physician and that a smear made from the cervix would make a greater number of cells available for examination. It has been previously emphasized by Cuyler[5] that examination of cervical specimens has yielded a higher degree of accuracy and that vaginal pool specimens alone could fail to contain cells from a significant number of both invasive and intraepithelial carcinomas. On the other hand, Graham[6] and others have reported excellent results with use of this latter method in hospital and clinic practice.

A significant argument for the obtaining of smears by vaginal aspiration was that no instrumentation would be necessary. This in itself would, we believe, attract a larger number of women, and an essential aim of this screening program was to reach the largest number of women possible. Furthermore, the finding of a sufficient number of physicians to make the examinations in a mass survey such as this would be a prodigious problem, and use of the vaginal specimen makes it possible for trained technicians to obtain the smear in the clinics established for this purpose. Thus, as a procedure for mass screening, the examination of smears obtained by vaginal aspiration was the method of choice, and it has been used in this study. Our experience to the time of writing, reviewed in this report, confirms the advantages of this choice.

One of the major tasks in initiating this project was to inform the women of Memphis of the opportunity afforded by this program and of the significance of the cytological examination of the vaginal smear. An essential phase of this program was to stimulate essentially well women to consider the prevention of clinical uterine cancer as a personal problem. The publicity consisted of an educational campaign designed to explain the value of this examination in the detection of unsuspected early uterine cancer in the presymptomatic stage in order to prevent the development of incurable cancer. Dissemination of information concerning this cancer survey project has been continuously aided by the excellent cooperation of local newspapers and radio and television stations. An extensive program of talks, including discussions concerning uterine cancer, cytological examination, and the objectives of this program, was arranged for women's church organizations, parent-teacher groups, and women's clubs and in industries and at business sites where temporary clinics were to be set up. The plans for all public relations were considered and approved by a committee appointed by the Memphis and Shelby County Medical Society. As a result of this close liaison with the county medical society, there has been excellent cooperation by the physicians of this area.

As previously described,[4] smears have been obtained both from women visiting physicians of this area and from those attending the clinics established for this purpose. At present, approximately 50% of the smears are received from the more than 300 participating Memphis and Shelby County physicians, while 50% are sent in by the special clinics set up in hospitals, health centers, 51 city and county school clinics, and 60 industrial or business sites. The clinics in schools and business centers are temporary clinics that are opened annually wherever there are 50 or more women. Such clinics are set up for from a few hours to three days, depending on the number of women.

The results of the examination are reported to the physician who obtained the smears, who in turn informs the woman tested. Reports are under no circumstances made directly to the women. When testing is done in the special temporary clinics in schools or industrial sites, each woman examined is requested to indicate her personal physician, to whom the report is to be forwarded. If findings indicate the need for follow-up studies, women unable to assume costs are referred to the special gynecologic clinic at a Memphis hospital that is maintained by the staff of the division of obstetrics and gynecology of the University of Tennessee for this purpose.

Classification of Smears.—In our laboratory, smears are classified as follows: type 1, normal; type 2, abnormal cells present, possibly suspicious; type 3, abnormal cells present, moderately suspicious; type 3a, cells possibly indicative of intraepithelial carcinoma; type 3b, cells indicative of intraepithelial carcinoma; type 3c, very abnormal cells, possibly indicative of invasive cancer; types 4 and 5, cells indicative of cancer. Specific diagnoses are not given to the physician. Instead, four types of reports are made: 1. Satisfactory: the physician is advised that this report means the patient can be told that no evidence of cancer was found but she is to be advised to return in a year. 2. Unsatisfactory: this report means the smear was not adequate for diagnosis. 3. Advised further study: this report indicates that the smear by our classification was a type 2; that is, a few suspicious cells were seen and cervical smear studies are requested. 4. Biopsy recommended: this report means that the smear was classed as type 3, 4, or 5 and that a tissue study is needed for definitive diagnosis.

It is important to emphasize the fact that, to increase the accuracy of this screening technique, all women who had smears classified as type 2 were requested to have further cytological studies. Approximately 3% of the women examined had smears classified as type 2; hence in one sense the vaginal smear is being used to indicate the need not only for tissue study by biopsy but for further cytological study.

Reference to the above method of reporting emphasizes again the philosophy that the cytological method has its greatest value and is being used in this project as a screen for the detection of all suspicious cases that deserve further study and not just as a diagnostic procedure. While it is apparent that the majority of symptomatic invasive uterine cancers will be diagnosed by conventional methods, a significant number of unsuspected invasive cancers are detected by cytology. But it is in the group of preinvasive cervical lesions (epithelial dysplasia, atypical metaplasia of the cervix and endocervix, and especially intraepithelial carcinoma) and asymptomatic invasive cancer that the cytological method is most productive of unsuspected cases that either are cancer or bear watching. This is the reason for our plan to request supplementary cytological examination of vaginal and cervical smears in all women with type 2 smears and to advise tissue study in all those with type 3 to type 5 smears. It is also apparent, however, that it is in women with this borderline group of smears, especially, that the cytological method is not sufficiently specific to diagnose cancer definitively. We believe that tissue study is essential for definitive diagnosis.

Results in 108,000 Women Examined Once

Up to the time of writing, more than 108,000 women have been examined once, 33,000 of these same women a second time, and over 8,000 at least three times. Previous reports have summarized the progress of this study after examination of 20,000, 60,000, and 80,000 women.[7] This report is concerned with the results in the first 108,136 women tested once and the first 32,728 who returned for a second examination.

The study reported here was completed in the three and one-half years ending December, 1955. The testing of half of the female population of this metropolitan area in this period tells the story of response obtained and answers the important question of how many women can be reached. It should be emphasized that this preliminary report includes data concerning specimens sent to the project laboratory from private physicians as well as from the special clinics of this area; thus, approximately 13% of the women examined were not residents of Shelby County, the designated test area. Further analysis with reference to residence, race, age, and source of specimens is now being carried out.

In 983 of each thousand women examined on first screening, no evidence of cancer or significant abnormality was found in the screening cytological study, while 17 of each thousand were advised to have further study by biopsy. (An additional 163 women were asked to return for repeat smear examinations because of unsatisfactory smears or minimal cytological change [type 2 smears]. Approximately 50% of the 163 did not return.) In table 1 it is seen that approximately 13 (77%) of the 17 women in each thousand for whom biopsies were requested did return. Of these 13 women, 8.6 were found to have some pathological change: 7.3 had intraepithelial carcinoma or cancer, and the remaining 1.3 showed a marked degree of atypical change that was considered to be a borderline lesion or possible intraepithelial carcinoma.

Table 1.—*Pathological Findings in 1,453 of 1,842 Women for Whom Biopsies Were Recommended as a Result of Examination of Vaginal Smears of 108,136 Women*

	No.		% of 108,000 Women
Invasive uterine cancer	373		0.31
Cancer of cervix		331	0.31
Cancer of corpus		42	0.04
Other genital cancers	20		0.02
Intraepithelial carcinoma of cervix	393		0.36
Total cancer and intraepithelial carcinoma	786		0.73
Atypical metaplasia	111		0.13
Findings normal	479		0.44
Total	1,406*		1.30

*Biopsies were inadequate in 47 women.

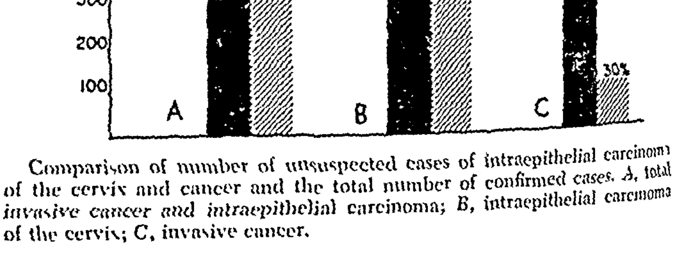
The very atypical epithelial metaplasia (which might show possible intraepithelial carcinoma) referred to in table 1, is important and significant; women with this type of lesion deserve careful follow-up study. If, as we believe, intraepithelial carcinoma is merely a stage in the sequentially developing process that, at least frequently and possibly always if left alone, leads to cancer, then its precursor, atypical epithelial metaplasia, is just as important to label, both for the prevention of uterine cancer and for study in furthering knowledge of the life history of this process. Obviously, too, because the pathological limits of intraepithelial cancer are arbitrary and cannot always be sharply defined and because interpretation is sometimes dependent on incomplete tissue samples, many of this group can be considered as merging with those lesions interpreted as intraepithelial carcinoma.

While the finding of four cases of intraepithelial cervical carcinoma per thousand women (0.36%) is believed to be an index of frequency of this lesion in the group that was screened, the rate of occurrence of invasive carcinoma as found in this survey probably does not represent an accurate index for this area. The latter data must be corrected by a morbidity survey t will be done to determine the number of women th clinically recognized cancer who did not have smears examined and thus are not included.[8]

Distribution According to Residence and Race.—The data concerning these 108,000 women are subject to review in a number of ways and, as previously indicated, will be analyzed and adjusted for age, race, and resident status and reported in detail at a later date. However, it is possible to discuss some of these factors at this time. While this survey is aimed primarily at residents of Shelby County, it would have been difficult to exclude persons not living in Memphis who come to Memphis physicians for their medical care. It is of interest to note that 134 (36%) of the 373 women with invasive uterine cancer were nonresidents, although nonresidents constituted only 13% of the women who were examined. While the figure of 239 cases of invasive cancer in residents is low and will be corrected by determining the number of additional cases of invasive cancer not seen in this study by a supplementary morbidity survey, these data give a crude rate of invasive cancer for the women of Memphis and Shelby County of 2.5 per thousand compared to 9.6 for the nonresidents. It is obvious that a significant number of the women coming to Memphis for examination had symptoms and may be said to have had their cancer diagnosed by conventional methods. This emphasizes the fact that the nonresidents were a selected group such as will be found in any hospital sampling. On the other hand, the rate of occurrence of intraepithelial carcinoma was similar for the two groups, as would be expected for this predominantly asymptomatic and unsuspected lesion.

Another important factor for analysis is the race incidence. Half of the cancers that were found were in Negroes, who constituted one-third of the surveyed population. This ratio was expected as shown by a morbidity survey for uterine cancer for this area for 1950 and 1951,[8] in which an incidence rate of 80 to 52 cases and a prevalence rate of 120 to 82 per 100,000 of Negro to white was found. Of interest is the fact that two-fifths of the intraepithelial carcinomas were found in the Negro women representing approximately one-third of those seen. These data are now being analyzed further with respect to source of specimen, i.e., whether it is from a private physician, health clinic, medical institution, industrial clinic, or city hospital clinic, to determine the comparative prevalence, especially of intraepithelial carcinoma, in these different groups.

Number of Unsuspected Cases Found.—Of particular interest in evaluation of the use of cytological screening for prevention of clinical cancer has been the question directed to the physician in each case, "Would a biopsy have been performed at this time if the smear had not been done?" It will be apparent that the number of unsuspected cases diagnosed is the most significant single criterion now available to us in assessing the value of this method in mass screening. The rates shown in the figure probably reflect a minimal figure, for it is likely that the publicity and educational program that were part of this project brought some of the patients with symptomatic cancer to their physicians at an earlier date than otherwise.



Comparison of number of unsuspected cases of intraepithelial carcinoma of the cervix and cancer and the total number of confirmed cases. *A*, total *invasive cancer and intraepithelial* carcinoma; *B*, intraepithelial carcinoma of the cervix; C, invasive cancer.

In the figure it is seen that 463 (59%) of the 786 cases of invasive cancer and intraepithelial carcinoma were unsuspected. We believe this to be a most significant and encouraging fact relating to the value of this program. Diagnosis in these women is directly attributable to detection by smear. This represents an unsuspected-case-finding rate of practically five women in a thousand. That the majority of the intraepithelial carcinomas would not otherwise have been discovered (353 of the 393 were unsuspected) was expected. It is interesting to note that the finding of unsuspected cases is not limited to this group of intraepithelial carcinomas, which are predominantly asymptomatic and not recognizable grossly. One hundred twelve (30%) of 373 cases of invasive neoplasia were labeled by the participating physicians as unsuspected (see figure).

Age Distribution.—The age distribution of women with uterine neoplasms is of special significance in indicating both the age groups that should be surveyed and how frequently testing should be done. Analysis to date indicates that the peak incidence of intraepithelial carcinoma is in women of from 30 to 34 years of age. This finding confirms the view that women 20 years of age and over should be included in any survey the purpose of which is to find this disease in its early stages. The apparent spread between the peak incidence of intraepithelial carcinoma in women from 30 to 34 years of age and that of invasive cancer in women from 50 to 54 years of age again supplements the previous evidence to the effect that, if, as is now generally accepted, intraepithelial carcinoma represents a stage in cervical carcinogenesis, it may take years to develop. It should be added that the data concerning age distribution are being analyzed with respect to the influence of the number of women in each age group as well as their race and place of residence.

Results of Reexamination of Thirty-Three Thousand Women

The second part of our plan provided for the reexamination at approximately yearly intervals for at least three years of as many as possible of those women examined once who were found to have no evidence of intraepithelial carcinoma or cancer in the first screening survey. It was our belief that this second phase of the study could contribute significant facts about the natural history of uterine cancer, with special reference to the more common squamous cell carcinoma of the cervix. When the incidence of new cases in an already screened population is known, the quantitative relation of intraepithelial carcinoma to cancer should be evident. Finally, such data concerning rescreening and a subsequent morbidity survey should indicate, by the number of preinvasive lesions and clinical cancers found as compared to the number found in the first survey, the effectiveness of this approach to control of uterine cancer in shifting the predominance from clinical to asymptomatic cancer. A brief summary of the methods, problems, and results of our efforts in the recall of the women for reexamination has been reported elsewhere.[7]

Table 2 shows the results of this second screening of 32,728 women. It is seen that, at the time of writing, only 244 (69%) of the 353 biopsies recommended had been performed. It is expected that in a few more months this percentage will have increased to at least the 79% of the first screening. In this table it is also shown that 83 intraepithelial carcinomas or cancers were found; 72 of them were intraepithelial carcinomas, 9 were invasive cancers of the cervix, and 2 were cancers of the uterine body.

It is of interest to compare the case-finding rates for the second screening with those for the first. Of each 1,000 women examined in the first screening, 3.6 were found to have intraepithelial carcinoma and 3.1 invasive cancer of the cervix. In the second screening, of each 1,000 women, 2.2 had intraepithelial carcinoma and 0.3 had invasive cancer of the cervix. It is believed that, when adjustment is made for differences with respect to race and age distribution between the women in the first and second screenings, the reduction in case-finding rates will be increased.

Reliability of Vaginal Smear as Screening Procedure

One of the more important problems in this study is how many cancers are missed by this screening procedure. A precise figure cannot be given until a sizable group of women has been examined three times. Our first precaution against error is through close contact with the physicians and hospitals. All cases of cancer of the reproductive tract are called to our attention. Since the onset of this survey there have been, among the women whose smears were classed as type 1, 13 intraepithelial carcinomas of the cervix, 11 squamous-cell carcinomas of the cervix (invasive), 6 adenocarcinomas of the uterus (corpus), and 8 cancers of other parts of the reproductive system. When the smears from these 38 women were reexamined, 19 were again classed as normal. The reason for this is not clear, but we consider it a sampling error; that is, there were too few suspicious cells in the vaginal pool for one to show up in the sample placed on the slide. Of the remaining 19 smears, 4 should have been classed as unsatisfactory; 6 were definitely errors, as suspicious cells were seen when these slides were reexamined, and biopsies should have been requested; and the remaining 9 in retrospect were classified as type 2—in other words, a few abnormal cells were seen.

Our second approach to the problem of error is through the reexamination of the smear made at the first screening of all those who had cancer or intraepithelial carcinoma at the time of the second examination. In table 2 it is seen that there were 72 women

TABLE 2.—*Pathological Findings in 244 of 353 Women for Whom Biopsies Were Recommended as a Result of Second Annual Examination of Vaginal Smears of 32,728 Women*

	No.		% of 33,000 Women
Invasive uterine cancer	11		0.033
Cancer of cervix		9	0.030
Cancer of corpus		2	0.003
Intraepithelial carcinoma of cervix	72		0.218
Total cancer and intraepithelial carcinoma	83		0.254
Atypical metaplasia	45		0.136
Findings normal	109		0.330
Total	237*		0.700

*Biopsies were inadequate in 7 women.

with intraepithelial carcinoma of the cervix. Of these 72 women, 26 had smears that had been read as normal on the first survey and were normal when reexamined. Twenty-one of these had an intraepithelial lesion and five had cancer. Thus, this group would appear to include the patients who had developed cancer since the first smear was taken. However, the possibility exists that the lesion was present and the vaginal sample failed to include cells representative of a lesion. Of the remaining 46 smears, 6 that were originally called normal should have been classified as suspicious (type 3 or 3a), and a biopsy should have been recommended. In another six women the original smear was type 2, and further cytological study was recommended but not done. Thirteen were called normal by the screening technicians and on review were reclassified as type 2, and these should have been studied further. Fifteen were originally called cytological types 3, 4, or 5, and biopsies were recommended, but seven of these women failed to have biopsies done; of the other eight, six had a tissue diagnosis of atypical metaplasia, in one the biopsy showed no abnormal change, and in the other biopsy was inadequate. Lastly, there were six smears that, it is now thought, should have been called unsatisfactory for adequate evaluation.

Thirdly, and perhaps most important, the *esprit de corps* of all workers in the cytology laboratory is kept high by keeping them informed of all phases of the study, so that they realize the results of a failure to mark a suspicious cell.

Comment

In this report, the term intraepithelial carcinoma has been used as synonymous with "in situ" as used by many. The histological and cytological features of this controversial lesion have been repeatedly discussed by many authors.[9] We agree that the essential features are that it is predominantly a lesion of the squamocolumnar junction or the endocervix and that cytologically it mimics cancer to greater or lesser degree and histologically involves and is limited to the epithelial surface or endocervical glands without invasion of underlying stroma. It is but one segment of the dynamic biological process of cervical carcinogenesis. We believe that its borders cannot always be sharply defined, and it must be recognized that the limits of pathological definition are dependent on personal experience and correlative study.

No attempt will be made to discuss the arguments for or against the current trend to accept this lesion as a preinvasive stage of cervical cancer. Suffice it to say that the experience of any critical observer reveals that this lesion is frequently associated with invasive cervical carcinoma and that the available evidence indicates that intraepithelial carcinoma may often be preinvasive cancer. Thus, intraepithelial carcinoma is now generally accepted as significant in relation to cancer of the cervix whether or not it is a potential or a preinvasive stage of the common squamous cell carcinoma of the cervix. Yet it is equally clear that the exact biological story is not known, and there are still insufficient data to indicate how often this sequential progression takes place or what percentage of cancers develop from reserve cell hyperplasia of endocervical or junctional areas to atypical metaplasia of varying degrees to intraepithelial carcinoma; that is, from surface, preinvasive carcinoma to invasive cancer.[10] The removal of these intraepithelial carcinomas and cervical cancers from a population to be examined annually has provided this investigation with the experimental stage to test the thesis that the lesion known as intraepithelial carcinoma of the cervix is the preinvasive stage of invasive cervical carcinoma.

We believe that further investigation, analysis of the data concerning the rescreening to determine the age-specific incidence of development, and the follow-up of the significant number of patients with what may be cancer in its early stages should contribute evidence to indicate more exactly the relationship of the cervical epithelial changes that lead to invasive cancer and enlighten this hazy but important controversial question. Though the biological story of this relation or its frequency is not yet fully elucidated, the available evidence clearly justifies and dictates judicious application of this knowledge to efforts directed toward prevention of or decreasing the morbidity and mortality of uterine cancer as in this project. Thus we have proceeded with the plan of this project on the thesis that the developmental stages of atypical metaplasia, dysplasia, and intraepithelial carcinoma were significant in relation to uterine cancer.

It is obvious (see figure) that the value of this or similar screening efforts is economically dependent on this relation, for the preponderance of unsuspected cases (77%) are of intraepithelial carcinoma. If intraepithelial carcinoma is not the forerunner of cancer in a significant percentage of cases, the cost would undoubtedly prohibit widespread use of cytological examination of vaginal smears as a screening procedure, for it would not pay the community to find only the smaller number of unsuspected invasive cancers, even though it would be advantageous to the individual involved.

It is of interest to compare the number of intraepithelial carcinomas diagnosed in residents of Shelby County in 1950 and 1951[8] to the number (465) found in the 108,000 women during the three and a half years of this project. Diagnoses during both periods were made by the same pathologists. More than a fourfold increase resulted from this large-scale application of cytological methods. A similar comparison cannot be made with invasive uterine cancer until another morbidity survey is completed to furnish data concerning cancers detected by means other than cytological screening.

Efforts were directed in our program to guard against false security as well as misunderstanding of the scope of the test. Each woman having the test has received a memorandum including the following statement: "Remember that this test detects cancer in the uterus (womb) only; it is not a test for cancer in other parts of the body. All women over 20 should have this test once a year as a health safeguard, like a chest x-ray. If symptoms should develop before your next test, see your doctor—don't wait." However, this effort in no way decreases the importance of the study of incidence of false-negative tests as a significant factor in evaluating the reliability of this approach. As previously discussed, supplementary information will be obtained from the repeat annual studies, so that restudy of at least three annual tests will be available for an accurate measure of reliability. Data now available not only indicate that the false-negative error is low for the first examination but suggest that the possible error disappears for all practical purposes if women are examined at yearly intervals.

The great advantage of the plan used in the Memphis project for this community is that, even though this is a mass project, the close doctor-patient relationship has been maintained throughout for follow-up diagnostic studies or treatment as indicated. Every effort has been made to maintain and foster this relationship between the women examined, their doctors, and the pathologists interpreting the cytological tests and tissue studies.

Until further knowledge permits efforts directed at prevention of cancer, this and similar investigations in cancer research are aimed at decreasing the incidence of incurable malignancy and at the prevention of deaths from cancer. Here attention has been directed at prevention of incurable disease by careful cytological examination, early diagnosis while the disease is still in a curable stage, and, thus, early treatment.

This program tests the thesis that, by detection and removal of intraepithelial and incipient cancer of the uterus, the situation can become one where cancers are found predominantly in the preinvasive and preclinical stage rather than in the symptomatic and frankly invasive stage. The trend indicated by the case rate for the 33,000 women (table 2) suggests that this approach to control of uterine cancer can be successful, but final conclusions cannot yet be drawn.

The trend indicated in this preliminary report offers evidence that suggests that this approach can be successful and that the present situation, where most cases are discovered at the symptomatic stage, which is usually too late for successful treatment, can be changed to one where the majority are found at the presymptomatic or localized stage, a stage at which available evidence indicates the cure rate can be very high. The final answer and measure of success of this approach will be determined by continuation of this study to determine changes in morbidity and mortality from this disease in this area.

Summary

A plan was devised for the screening of a whole population for the early detection of cancer of the uterus. Among the 108,000 women examined for the first time there were 393 intraepithelial carcinomas; of these, 353 (90%) had not been suspected. There were also 373 invasive cancers of the uterus, of which 112 (30%) were unsuspected. This shows clearly the value of this procedure as a method for the early detection of cancer. On the second examination of 33,000 women, 2.2 with intraepithelial carcinomas were found per thousand, as compared with 3.6 on the first examination, while the rate for invasive cancer was reduced from 3.4 to 0.3 cases per thousand women. These changes are related to the natural history of cancer.

Growth Retardation in Renal Disease.—In an effort to determine a common denominator for the growth failure of renal disease, the clinical and laboratory observations on 41 children with chronic renal disorders have been surveyed. Twenty-one of the patients had growth retardation. Of the manifestations investigated, none met the criterion of being universally present in the stunted patients and absent in children growing normally. Failure of renal concentrating ability was present in all children with growth failure, but failure of concentration was also observed in a few children growing normally. On the other hand, chronic acidosis was never observed in children growing normally but was present in only 76% of the retarded children. There was no evidence that mild azotemia, albuminuria, or chronic urinary tract infection significantly affected growth. The advent of chronic acidosis in a patient with renal disease appeared to cause stunting by producing temporary growth arrest. After stature had become subnormal, growth was resumed at a slow rate, although acidosis continued to be present. The role of low caloric intake resulting from anorexia as a cause of growth retardation in renal disease can only be assessed roughly in the present study by the weight-for-height index. According to this assessment only eight of the retarded children fall into the category of hypocaloric dwarfs. Two other children demonstrated a growth spurt after establishment of adequate urinary drainage by surgery, indicating that their dwarfism might also have been a result of low caloric intake. It was found that between the two factors of low caloric intake, as assessed by the above methods, and chronic acidosis, the growth retardation of nearly all the patients in the present series could be accounted for.—C. CHLORPROMAZINE IN THE TREATMENT OF PORPHYRIA

James C. Melby, M.D., John P. Street, M.D.
and
C. J. Watson, M.D., Minneapolis

• *Chlorpromazine was administered by mouth, generally in doses of 25 mg. three or four times daily, in nine cases of intermittent acute porphyria with pain and other serious symptoms. This dosage sufficed to control the symptoms in most cases, although it did not cure established paralyses. In three of the patients a single dose of 100 mg. of chlorpromazine was followed by complete clinical remission. The first effect was a relief of the nervous symptoms, including the pain; this improvement was not correlated with any significant changes in excretion of porphyrin or porphobilinogen during the period of study. The drug appeared to interrupt a vicious cycle, after which the patient was able to regain a state of remission spontaneously. Chlorpromazine has been the most consistently effective remedy thus far available for the pain and nervous manifestations of porphyria.*

To date, no agent has been found that will correct the metabolic defect of porphyria. Certain ganglioplegics, corticotropin, and hydrocortisone or its analogues have been thought, in some cases, to interfere with the progress of acute attacks of porphyria. However, the response is extremely variable, and, because of the occurrence of spontaneous remissions, conclusions have not been possible. An important factor in the evaluation of any agent in the treatment of porphyria is the possible aggravation of the disease by the chemical. Thus, it is well known that barbiturates and certain other chemicals can precipitate attacks of acute porphyria in individuals with latent disease.[1] This fact indeed has made one especially conservative about a trial of new agents. Our own experience with the use of tranquilizing agents has undoubtedly been retarded because of concern at the outset that we might do more harm than good. However, the great difficulty encountered in treating cases of porphyria induced us to make trials of some of the newer agents. Our actual point of departure was the idea of enhancing the effect of meperidine (Demerol) hydrochloride or of diminishing the required amount.

The purpose of the present report is to describe experience during the past year with the use of chlorpromazine and, to a lesser extent, the Rauwolfia alkaloids in cases of intermittent acute porphyria. Nine cases are included in this report. Six of these were studied at the University of Minnesota and Minneapolis Veterans hospitals. The clinical protocols and results of chlorpromazine therapy in three cases have been made available to us by physicians in other cities.

Report of Cases

Case 1.—A 36-year-old female was admitted to the University of Minnesota Hospitals on Feb. 5, 1956, complaining of severe, crampy abdominal pain. She had been in good health until Jan. 7, 1956, when she had begun to have attacks of vomiting abdominal pain and passed dark urine. The patient was italized elsewhere and received parenterally given fluids, tics, and barbiturates. Because of persistent abdominal ain, an exploratory laparotomy was performed on Jan. 22, 1956, at which time a normal appendix was removed. Her symptoms continued, and on Feb. 4, 1956, the urine was first found to be positive for porphobilinogen. The diagnosis of porphyria was made by Dr. D. S. Morris, Winston-Salem, N. C., who referred the patient to us.

Physical examination revealed abdominal tenderness without rigidity or distention and diminished posture sense of the lower extremities. Four days later the left biceps reflex was absent, and there was transient mild weakness of the left arm. The amounts of urinary porphyrin excreted daily are shown in figure 1. On Feb. 6, 1956, the patient's abdominal pain promptly abated after the intramuscular administration of 50 mg. of chlorpromazine. At the same time she began to eat and said she felt well for the first time since the onset of her illness. Because of recurrence of abdominal pain, chlorpromazine was given orally in gradually decreasing amounts, as noted in figure 1. Therapy was discontinued on Feb. 18, 1956, and the patient was discharged two days later without symptoms.

The patient has remained in good health up to the present time. Recently urinary porphyrin and porphobilinogen excretion studies were made. The porphobilinogen excreted in the urine was 28 units in 24 hours; the coproporphyrin excreted was 370 mcg. in 24 hours, and uroporphyrin excreted was 1,560 mcg. in 24 hours. A comparison of these values with the final daily excretions represented in figure 1 shows little change except that the excretion of coproporphyrin has diminished.

Case 2.—A 69-year-old female who was known to have had hypertension for three years was admitted to the University of Minnesota Hospitals on Sept. 27, 1955. Four weeks prior to admission, she had developed tremor and agitation and had been placed on mephobarbital (Mebaral) therapy. Shortly after this she began to have abdominal pain, nausea, and vomiting episodes and passed port-wine-colored urine, which was found to be positive for porphobilinogen by Dr. H. A. Christianson, Jackson, Minn. Physical examination on admission revealed grade-2 hypertensive retinopathy, cardiac enlargement, and a tender, distended abdomen. The blood pressure was 190/120 mm. Hg. One freshly voided specimen of urine was positive for porphobilinogen, and all subsequent specimens were negative. Data on the urinary porphyrin excreted daily are given in figure 2. Chlorpromazine was administered in amounts of 25 mg. four times daily for four days, during which time the abdominal pain gradually subsided. On the fourth hospital day the patient had one brief recurrence of abdominal pain, which quickly disappeared and did not recur. Chlorpromazine was withdrawn on Oct. 24, 1955, and the patient was discharged asymptomatic on Oct. 28, 1955.

Case 3.—A 66-year-old male was first admitted to the Minneapolis Veterans Hospital in 1951. Intermittently for 11 years he had had abdominal pain and hypertension and passed dark urine and had experienced a change in personality. At that time the diagnosis of intermittent acute porphyria was first established. He had had remissions while on corticotropin therapy on two occasions. In the fall of 1955, he had received prednisone without benefit but had had fleeting relief of abdominal pain on pentolinium therapy. At that time meperidine hydrochloride was withdrawn (the patient was strongly addicted). After a period of delirium, for which he was given large doses of reserpine (1 to 2 mg.), he became more lucid and tractable. Reserpine was withdrawn, and within a short time the patient

---

From the Department of Medicine, University of Minnesota Hospitals and Minneapolis Veterans Hospital.

experienced a severe exacerbation of generalized aching and abdominal pain associated with dark urine and anasarca. Pleural effusions were present, the blood pressure was 240/120 mm. Hg. and ileus with abdominal distention was noted. The patient was placed on a combined chlorpromazine (50 mg. four times a day) and reserpine (0.25 mg. four times a day) regimen with apparent marked relief of abdominal symptoms, tremulousness, and agitation. The edema abated. He then had an attack of abdominal pain and generalized aching in December, 1955. Chlorpromazine (50 mg. four times a day) and reserpine (0.25 mg. four times a day) were again given with sustained relief of symptoms. The patient has been relatively asymptomatic without medication up to the present.

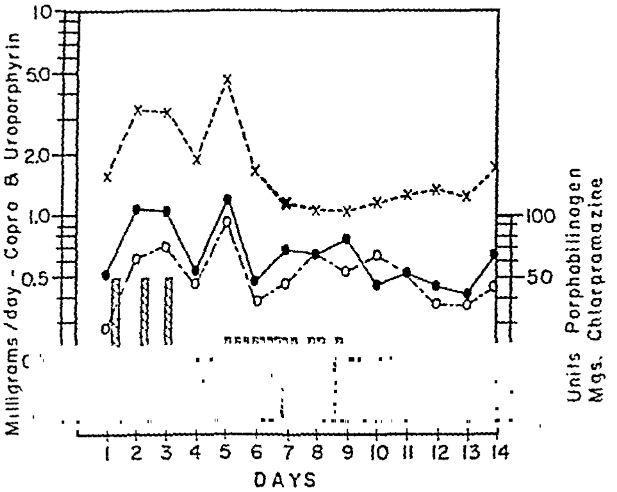

Fig. 1.—Daily excretion of urinary porphyrin and porphobilinogen plotted on a semilogarithmic scale during administration of chlorpromazine. Dosage is shown as divided through 24-hour periods. Levels of uroporphyrin are indicated by X's connected by broken lines, of porphobilinogen by O's connected by long and short lines; of coproporphyrin by black dots connected by unbroken lines.

This man had been difficult to manage on previous hospitalizations because of his psychotic behavior and extreme agitation during acute episodes of abdominal pain. The tranquilizing effects of chlorpromazine and reserpine were decisive in altering the patient's course and in avoiding the use of narcotics.

Case 4.—A 24-year-old male was admitted to the Minneapolis Veterans Hospital on Aug. 9, 1955, following transfer from another hospital, where he had developed a flaccid quadriparesis. Four months earlier the patient experienced crampy abdominal pain, nausea, vomiting, and constipation, which increased in severity until the onset of quadriparesis. Four years previously he had had an episode of abdominal pain, and his urine had been red intermittently since then. Physical examination on admission revealed flaccid quadriparesis. The excretion of uroporphyrin and coproporphyrin in the urine was markedly increased. The test for urinary porphobilinogen was strongly positive. The paralysis largely abated within a week, with a residual bilateral palsy of the radial nerve. While in the hospital, on Nov. 10, 1955, the patient developed severe abdominal pain, vomiting, and agitation. Corticotropin, prednisone, pentolinium, intravenously given procaine, and tetraethylammonium chloride (Etamon) were all administered individually without benefit. The patient required large doses of meperidine hydrochloride for control of pain. Chlorpromazine in 25-mg. amounts was given intramuscularly at six-to-eight-hour intervals. The meperidine requirement dropped but pain persisted, and on Dec. 8, 1956, the patient was given 100 mg. of chlorpromazine intramuscularly. He became completely asymptomatic within one hour. He was discharged two days later, having required no further medication. He was readmitted on Feb. 9, 1956, with severe abdominal pain and was promptly given 100 mg. of chlorpromazine intramuscularly with immediate and complete subsidence of the attack. At the present time the patient is symptom-free except for the persistence of bilateral wrist drop. In this case, it was evident that the optimal response to chlorpromazine was obtained only after the administration of a large single dose, smaller doses given intermittently being much less effective.

Case 5.—A 23-year-old male admitted in May, 1955, had had crampy abdominal pain, attacks of vomiting, and constipation and had passed dark-red urine for 10 days. He had noted red urine intermittently for one year prior to admission. The blood pressure was 170/110 mm. Hg. The urine was positive for porphobilinogen, and the daily excretion of coproporphyrin and uroporphyrin was markedly elevated. Relief from abdominal symptoms occurred after the administration of pentolinium and corticotropin therapy. Because of severe apprehension and anxiety, he was placed on reserpine therapy (0.25 mg. twice a day) and attained complete relief. On three subsequent occasions the patient stopped taking the medicament, and there was recurrence of extreme nervousness and mild abdominal pain on each occasion. Each time the symptoms abated after the reinstitution of reserpine therapy. On March 19, 1956, he was readmitted to the hospital and given meprobamate (400 mg. three times a day). Within 9 days he experienced moderate abdominal distress and in 18 days developed a full-blown attack of porphyria with severe abdominal pain, vomiting, constipation, and hypertension. Use of meprobamate was discontinued. Chlorpromazine was given (25 mg. three times a day intramuscularly) with moderate relief in two days, and the attack subsided 36 hours after four spaced doses of 100 mg. of chlorpromazine were given intramuscularly.

Daily amounts of urinary porphyrin excreted during therapy with chlorpromazine are shown in figure 3. It is not clear why there should be such an abrupt rise in the excretion of uroporphyrin. A part of this may be artefact on the basis of conversion of porphobilinogen to uroporphyrin after the urine was passed.

The patient's history suggests that use of reserpine may have aborted full-blown porphyric symptoms, in that mild symptoms occurred upon withdrawal of the drug and disappeared on readministration of reserpine. Use of meprobamate did not modify the acute attack, and the drug may even be suspect in its precipitation. Chlorpromazine relieved symptoms when given in relatively large amounts (100 mg.) intramuscularly. The patient is asymptomatic at the present time.

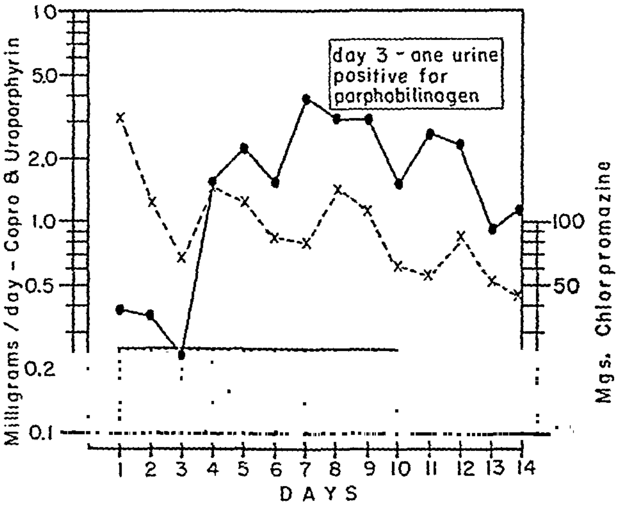

Fig. 2.—Daily excretion of urinary porphyrin plotted on a semilogarithmic scale during administration of chlorpromazine. One freshly voided urine specimen on the third day gave a positive reaction for porphobilinogen. Porphobilinogen was not detectable in the urine after the third day. Dosage is shown as divided through 24-hour periods. Levels of uroporphyrin are indicated by X's connected by broken lines and of coproporphyrin by black dots connected by unbroken lines.

Case 6.—In 1952 a 26-year-old female noted abdominal pain and dark urine. It is of possible interest that the patient had been exposed in her work to the fumes of molten lead for a period of two years before and up to this first outspoken attack of porphyria. An appendectomy was performed in 1952. In June, 1954, the diagnosis of porphyria was established during an episode of abdominal pain, vomiting, and delirium. She was first admitted to Barnes Hospital in St. Louis, on

Nov. 30, 1954, with recurrence of porphyric symptoms, for which she was given small doses of chlorpromazine. A remission occurred. During a second admission on Feb. 23, 1955, a remission was again observed after cortisone therapy. The patient then had severe headaches that disappeared when small doses of chlorpromazine were given. A third admission on Aug. 24, 1955, was occasioned by a recurrence of generalized aching and abdominal cramps, which did not respond to cortisone or prednisone but promptly abated on chlorpromazine therapy. On two subsequent occasions abdominal pain rapidly disappeared after use of chlorpromazine (10 mg. four times a day). A recent recurrence of porphyric symptoms on March 7, 1956, was again treated with chlorpromazine therapy (25 mg. four times a day). Within 24 hours of the increase in dosage she was greatly improved, and within 48 hours she was entirely free from pain. A definite correlation between the exacerbation of porphyric symptoms and psychological stresses was noted. At the present time the patient is feeling well on chlorpromazine therapy (25 mg. four times a day).

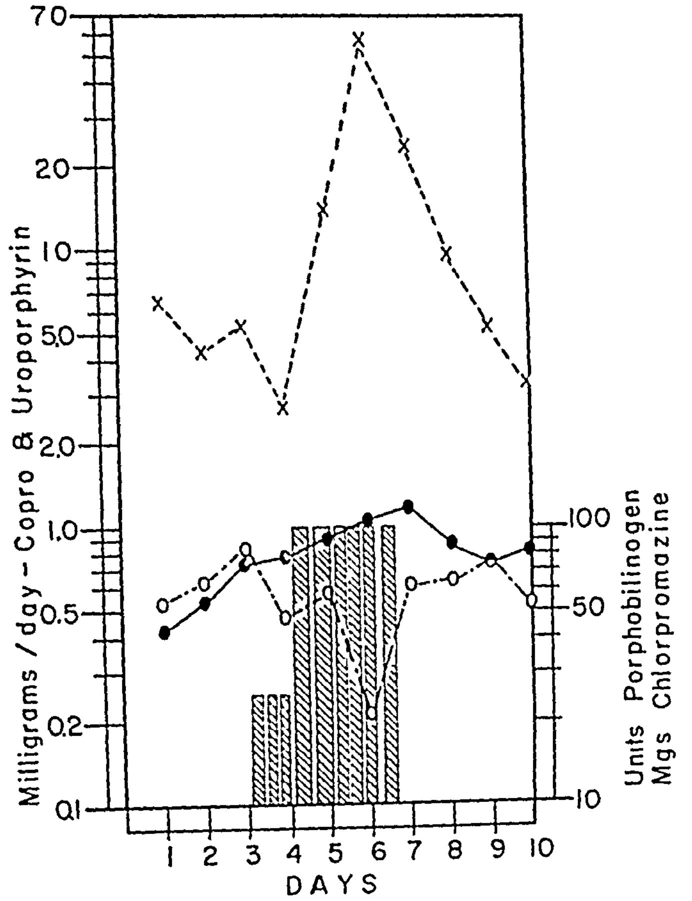

Fig. 3.—Daily excretion of urinary porphyrin and porphobilinogen plotted on a semilogarithmic scale during administration of chlorpromazine. Dosage is shown as divided through 24-hour periods. Levels of uroporphyrin are indicated by X's connected by broken lines, of porphobilinogen by O's connected by long and short lines, of coproporphyrin by black dots connected by unbroken lines.

Case 7.—A 35-year-old female had nausea, attacks of vomiting, and crampy abdominal pain in November, 1955. She was hospitalized elsewhere for a short time and was discharged unimproved. The patient was examined by another physician the day of her discharge and was rehospitalized one week, after which she developed a flaccid quadriparesis that was diagnosed as conversion hysteria. She was sent to a state psychiatric institution, where she was said to have diabetes and a gastric ulcer. The patient received isophane (NPH) insulin, 40 units every day, and propantheline (Pro-Banthine) bromide and was on a full ulcer regimen. Her abdominal symptoms improved, and the quadriparesis abated. A few days after her discharge from the state hospital, she came under the care of her present physician and complained of epigastric distress and weakness of the wrists and feet. Physical examination revealed abdominal tenderness and hypertension. The blood pressure was 160/110 mm. Hg. She was given phenobarbital (30 mg. four times daily) and continued on insulin therapy. In one week she returned to her physician complaining of nausea, vomiting, and severe, diffuse, crampy abdominal pain. On physical examination there was abdominal tenderness and bilateral wrist and foot drop. The urine was noted to be port-wine in color. A 24-hour urine specimen was sent to our laboratory. Porphobilinogen was present (54 units). Levels of porphyrins were markedly elevated, with a uroporphyrin concentration of 3,281 mcg. and a coproporphyrin concentration of 306 mcg.

Two weeks after the patient entered the hospital she was placed on chlorpromazine therapy (25 mg. three times a day intramuscularly). Her symptoms completely abated within five days. She was discharged while on chlorpromazine therapy (25 mg. twice daily). She had intermittent leg pain and was referred to us by Dr. R. L. Coultrip, Cooperstown, N. D., and she was admitted on May 29, 1956. The patient continued to have intermittent leg pain, which appears to be related mainly to passive or active exercise associated with physiotherapy. She had had no further abdominal pain while receiving chlorpromazine. In order to determine more exactly the effect of chlorpromazine, it was withdrawn temporarily. Two days later she had severe abdominal pain for the first time in months. It should be noted that she had been receiving ethinamate (Valmid) for a number of days to induce sleep. She had abdominal pain on two successive days relieved temporarily by meperidine. On the third day, because of severe abdominal pain she was given 100 mg. of chlorpromazine intramuscularly, with prompt and complete relief that lasted four hours. The pain then recurred, and 100 mg. of chlorpromazine was again given, with complete relief for six hours. This pattern has been observed on a number of occasions subsequently up to the present writing, and the patient is still under observation. It is at least evident that the relief of pain following chlorpromazine in this case, although prompt and complete, was not as enduring as in the other cases of the series. At present the possibility that other chemicals such as ethinamate may have tended to aggravate the porphyria is being investigated.

Case 8.—A 35-year-old female had had symptoms of insomnia, irritability, headaches, and severe leg pains since December, 1955. Two first cousins were known to have porphyria (confirmed in this laboratory). The patient's symptoms are greatly increased at the time of her menstrual period, and the urine usually becomes quite dark during menses. At one time the patient was placed on ethchlorvynol (Placidyl) therapy, after which dark urine and porphyric symptoms appeared. She required meperidine hydrochloride and alkaloids of opium (Pantopon) for relief of pain much of the time. Recently the patient was given chlorpromazine, 20 mg. every six hours, and has shown marked improvement, which has been sustained. She no longer requires narcotics or sedatives. A 24-hour urine specimen was collected on May 19, 1956, shortly after the commencement of chlorpromazine therapy. Urinary porphobilinogen and porphyrins were measured in our laboratory. The value for porphobilinogen was 79 units, for coproporphyrin 1,454 mcg., and for uroporphyrin 11,095 mcg. per day. After an interim without further symptoms, an additional 24-hour sample, collected from May 31 to June 1, 1956, contained 1,180 mcg. of coproporphyrin, 8,700 mcg. of uroporphyrin, and 56 units of porphobilinogen.

Case 9.—A 28-year-old male had what was thought to be a "nervous breakdown" with severe generalized and abdominal pain and intermittent episodes of abdominal pain three years prior to hospitalization on Aug. 20, 1955. Six months prior to this, the patient had had severe constipation that required administration of large amounts of laxative. Physical examination on admission was negative except for the presence of diffuse abdominal tenderness. The urine was noted to be dark red. Because of concomitant pyuria, the patient was thought to have a severe urinary tract infection, and he was then treated with sulfisoxazole (Gantrisin), meperidine, and phenobarbital until Aug. 24, 1955. The first urine sample examined for porphobilinogen was negative, but later specimens were positive. An aliquot of a 24-hour urine specimen was studied in our laboratory. The specimen was collected on Aug. 27, 1955. The porphobilinogen concentration was 24 units, that of coproporphyrin 338 mcg., and that of uroporphyrin 86 mcg. per 24 hours. All these values are only moderately elevated and would accord well with the diagnosis of intermittent acute porphyria in remission. Chlorpromazine (50-75 mg.) was given on Aug. 24, 1955, and at irregular intervals until Aug. 27, 1955, when it was given orally (50 mg. four times a day). By Aug. 27, 1955, the abdominal pain, constipation, and nervousness had largely abated. The symptoms were controlled while on chlorpromazine therapy, and remission was obtained. In the past nine months the patient has had three attacks of abdominal pain, which have not been treated with chlorpromazine.

Comment

The precise action of chlorpromazine in diminishing or abolishing the clinical manifestations of acute porphyria is unknown. It has been asserted repeatedly that chlorpromazine inhibits the sympathetic diencephalic centers and has certain direct adrenolytic actions.[2] Control of anxiety, hyperkinesis, and reversal of the action of certain psychotomimetic drugs (mescaline and lysergic acid diethylamide) are established effects.[2c] The use of chlorpromazine in intractable pain of malignancy,[3] chronic pancreatitis, causalgia,[4] and many types of pain of visceral origin is accompanied by diminished requirement of narcotics, which Rome believes is not unlike the response to prefrontal lobotomy,[5] in which apparently pain is not abolished, but the patient becomes much less aware of its presence. This does not appear to be the case in those patients with intermittent acute porphyria who have responded favorably to chlorpromazine, as they disclaim any perception of abdominal pain. The striking abolition of the apprehension and agitation of the porphyric state, which often results, is apparently independent of the slow recovery from the disorder of the nervous system that results in paralysis.

There are a few references in the literature to the use of chlorpromazine and the Rauwolfia alkaloids in porphyria. Coulonjou, Pouderoux, and Derouet[6] describe one patient with intermittent acute porphyria with severe abdominal pain, vomiting, and neurological deficit who responded within a few hours, with subsidence of the abdominal manifestations after one dose of chlorpromazine given parenterally. Weakness of muscles also improved. A subsequent attack of abdominal pain, vomiting, and apprehension terminated one-half hour after the administration of chlorpromazine. They concluded that chlorpromazine reduced the duration of attack. Durst and Krembs[7] mention the case of a gravid female who experienced severe hyperemesis and abdominal distress after attempting abortion with intravaginal use of potassium permanganate and whose urine was positive for porphobilinogen. This patient obtained relief following parenteral use of chlorpromazine. Martin and Heck[8] in their review of the cases of porphyria seen at the Mayo Clinic state simply that chlorpromazine had been used with "good results" in some patients with abdominal pain. Muller[9] reported a case of intermittent acute porphyria in a young woman in whom intense abdominal pain, unceasing vomiting, high fever, and severe prostration rapidly resulted in a moribund state. The so-called lytic cocktail, consisting of intravenously given chlorpromazine, meperidine (Pethidine) hydrochloride, and promethazine hydrochloride, was administered for six days, with refrigeration of the patient for the first 36 hours. A complete remission was obtained, and the patient remained well during a three-month follow-up period. Although chlorpromazine was not used as the sole therapeutic agent in this case, our own experience would suggest that artificial hibernation with the production of hypothermia was an unnecessary adjunct. Kark[10] used Rauwolfia serpentina in two cases of intermittent acute porphyria and observed beneficial tranquilizing effects in both instances.

No data have been given as to the alterations in excretion of porphyrin or porphyrin precursor in the urine of any of the patients described in the literature who have been treated with chlorpromazine or the Rauwolfia alkaloids. Our own results bearing on this point are inconclusive. In general, it appears that the beneficial effects of chlorpromazine that we have noted are not correlated with changes in excretion of urinary porphyrin or porphobilinogen. Thus, in case 1, despite subsidence of symptoms shortly after the first dose of chlorpromazine, there was actually a considerable increase in excretion of porphyrin and porphobilinogen, which lasted through the fifth day, and at no time did this excretion fall below the initial level. In case 2 it was of interest that the uroporphyrin-coproporphyrin ratio became sharply reversed soon after chlorpromazine therapy was begun. This reversal has often been noted in the past in remissions of acute porphyria. In case 5 (fig. 3) there was a transitory sharp increase of excretion of uroporphyrin. But, as already noted, this may be due in part, at least, to conversion of porphobilinogen to uroporphyrin after the urine was passed. It is evident that there was no change in the excretion of porphyrin or of porphobilinogen that could be correlated with the patient's improved status. Since it is quite clear from previous studies that in well-established remissions the amounts of porphyrin and porphobilinogen excreted are on the average much less than those during the acute relapse,[1] one must consider that the effect of chlorpromazine therapy is indirect in abolishing the pain and nervousness. It may be that the effect is akin to interrupting a vicious cycle. Once it is interrupted, the patient can regain a state of remission spontaneously. Such a theory would necessarily assume that nervous factors in themselves are significant in precipitating relapse. General experience dating from the early work of Günther[11] tends to support such a concept. Günther emphasized the nervous background of the person with acute porphyria and gave it the name "phorphyrismus," by which he meant a peculiar constitutional instability of the nervous system.

Meprobamate is thought to produce selective blocking of transmission of impulses to internuncial neurons, muscle relaxation, and mild central depression.[12] Although our experience is too limited to make any definite conclusions, the one patient given the drug because of apprehension experienced increased nervousness and anxiety and developed severe abdominal pain, vomiting, and a striking rise in excretion of porphyrin and porphyrin precursor in the urine while on therapy with the drug.

Summary and Conclusions

In nine cases of intermittent acute porphyria, administration of chlorpromazine has been followed promptly by disappearance of pain and nervous symptoms. Established paralyses have been unaffected. In the majority of patients, 25 mg. given three or four times daily appeared to be sufficient to control symptoms, but in three patients a single 100-mg. dose was first followed by complete clinical remission. In one of the three, the effect of chlorpromazine during a subsequent mild relapse of pain was of relatively short duration. No definite evidence has been obtained that a reduced excretion of porphyrins or porphobilinogen is an early effect of chlorpromazine therapy. It is possible that the drug interrupts a vicious cycle, permitting a spontaneous remission to occur.

In two cases Rauwolfia alkaloid has been of value in maintenance therapy. In both instances there was absence of nervous symptoms when the patients were receiving the drug, and there was recurrence when the drug was withdrawn. The present experience indicates that chlorpromazine, in relation to other chemicals, is at least reasonably safe in cases of acute porphyria. There has been no suggestion that its use precipitates a relapse of the disease. It is the most consistently effective remedy thus far available for the pain and nervous manifestations.

Drs. Edward H. Reinhard and Samuel Goldfein, Washington University School of Medicine, St. Louis; Dr. Estle P. Muncy, Jefferson City, Tenn.; and Dr. Thomas D. Johnson, Albany, Ga., gave permission to report cases 6, 8, and 9 respectively.

This study was aided by a grant from the John and Mary Briggs Fund for Research on Porphyria.

CHLORAMBUCIL IN TREATMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA AND CERTAIN LYMPHOMAS

John E. Ultmann, M.D., George A. Hyman, M.D.
and
Alfred Gellhorn, M.D., New York

• *Chlorambucil was administered by mouth in doses ranging from 5 to 30 mg. daily for five to seven weeks, so than an average course amounted to 350 mg. Thirty patients were thus treated for lymphocytic leukemias and various lymphomas. In the largest group, namely, 18 patients with chronic lymphocytic leukemia, 3 patients obtained excellent results, in that the hemoglobin level and white blood cell count returned to normal, the differential count was significantly improved, and hepatosplenomegaly and lymph node enlargement disappeared. Eight other patients of this group obtained good results in that the white blood cell count fell, the hemoglobin level rose, the differential count improved, and the liver, spleen, and lymph nodes decreased in size. Results in cases of lymphocytic lymphosarcoma and Hodgkin's disease were less encouraging. In the dosages used, chlorambucil was practically without side-effects.*

In their systematic investigation of the carcinogenic and chemotherapeutic properties of the alkylating agents, Haddow and his associates of the Chester Beatty Research Institute in England [1] examined a variety of aliphatic and aromatic nitrogen mustards. In the course of their study, they found that certain aliphatic alkylating agents particularly depressed myelopoiesis. This lead to the development of busulfan (Myleran), which has been discussed extensively in recent articles.[2] Administration of certain aromatic alkylating agents, on the other hand, led to a specific decrease in circulating lymphocytes. One of these aromatic nitrogen mustards is chlorambucil [*p*-(di-2-chloroethyl) aminophenylbutyric acid], also called CB 1348. The relationship of chlorambucil to other alkylating agents is shown in the figure. The physical and chemical properties of this agent have been described.[3] Haddow found that in rats chlorambucil inhibited Walker carcinoma 256 in doses that had only slight effect on the white blood cell count of normal rats.[4] Elson [1a] as well as Bollag [5] demonstrated that large doses had a profound effect on the lymphocytes of the rat, causing a rapid fall without substantial influence on the granulocytes. This apparent "specificity" prompted investigation of the use of this drug in those conditions in man in which an abnormal proliferation of lymphocytes is found.

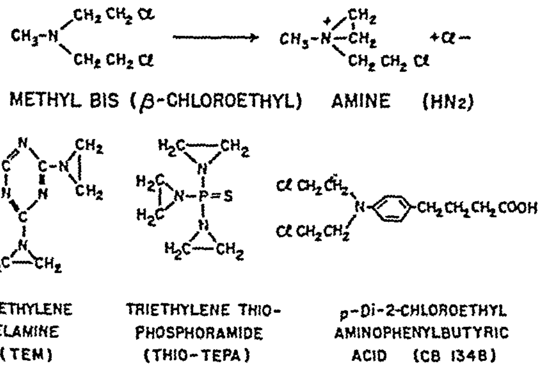
From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the medical services of the Francis Delafield Hospital and the Presbyterian Hospital, Dr. Ultmann is a Clinical Fellow (Hematology) of the American Cancer Society.

Material and Results

Thirty patients have been treated with chlorambucil at the Francis Delafield Hospital and Presbyterian Hospital since August, 1954. Eighteen patients had chronic lymphocytic leukemia, one giant follicular lymphoma, five lymphocytic lymphosarcoma, and six Hodgkin's disease. The diagnosis in each patient was established by history, physical examination, and hematological studies, usually including bone marrow aspiration. Surgical biopsies of lymph nodes were performed in all patients with lymphomas. Complete blood cell counts and platelet counts were made right before the start of therapy and three times weekly for hospitalized patients and less often for clinic patients. Only in rare instances were bone marrow aspirations repeated. Radiological and other laboratory studies, including hepatic and renal function studies, were performed at appropriate intervals. Following completion of a course of therapy, patients were seen regularly in the outpatient clinic.

Chlorambucil was available in 2 and 10-mg. tablets, which were stored in tightly stoppered brown bottles in a dark, cool place because of chemical instability. Administration was by mouth in all cases. With a standard daily dose of about 0.1 to 0.2 mg. per kilogram of body weight, an average course in most cases consisted of 6 mg. per kilogram. We have usually employed single daily doses of 6 to 10 mg.; however, individual doses ranged from 5 to 30 mg., depending on the weight of the patient, diagnosis, hematological picture, and previous therapy. A course of therapy usually lasted five to seven weeks; however, three patients were treated for 14 or more consecutive weeks. The average total dose was 350 mg.; the total effective dose varied widely in different patients, one receiving as little as 50 mg., while some received over 900 mg. The results of therapy in the four groups of patients are summarized in table 1.

Chronic Lymphocytic Leukemia.—Eighteen patients with chronic lymphocytic leukemia were treated with 20 courses of chlorambucil. All patients except one (case 18, table 2) were treated because of symptomatic conditions. Table 2 gives sex and age of patients and duration of disease prior to commencement of the experimental therapy, previous treatment and its effect, pertinent details of chlorambucil dosage with results, and the present status of patients. Objective improvement was rated as "excellent" when the hemoglobin level and white blood cell count returned to normal and when there were significant improvement of the differential count and disappearance of hepatosplenomegaly and lymph node enlargement; as "good" when there were a significant fall in white blood cell count, a slight change in differential count and rise in hemoglobin level, and a decrease in the size of the liver, spleen, and lymph nodes; as "slight" when the white blood cell count fell significantly, there was little improvement in differential count and hemoglobin level, and there was a slight decrease in size of liver, spleen, and lymph nodes; and as "none" when there was no effect. *Subjective improvement was rated as* "marked" when patients no longer had complaints that they had had on admission and were able to return to their activities with a sustained period of well-being; as "moderate" when they no longer had the complaints and returned to limited activities; and as "none" when there was no effect on their complaints and they were unable to resume activities.



METHYL BIS (β-CHLOROETHYL) AMINE (HN2)

TRIETHYLENE MELAMINE (TEM)

TRIETHYLENE THIO-PHOSPHORAMIDE (THIO-TEPA)

p-DI-2-CHLOROETHYL AMINOPHENYLBUTYRIC ACID (CB 1348)

Structural formulas of the nitrogen mustard methyl-bis (β-chloroethyl)-amine and related compounds, including chlorambucil.

TABLE 1.—*Results of Therapy with Chlorambucil in Thirty Patients*

		Objective Improvement			Subjective Improvement
Diagnosis	Patients, No.	Excellent	Good	Slight None	Marked or Moderate
Chronic Lymphocytic leukemia	18*	3	8	9	8
Giant follicular lymphoma	1	..	..	1	0
Lymphocytic lymphosarcoma	5	..	2	3	0
Hodgkin's disease	6	..	1	5	1

* 20 courses.

A significant fall in the white blood cell count to less than 30% of initial values was observed in 14 instances. In one patient (case 15), although the white blood cell count fell from 280,000 to 78,000 per cubic millimeter, the blasts, which had at first been 5%, actually increased to 75% on smear. Of the patients in whom there was a fall in white blood cell count, the percentage of lymphocytes was decreased by 25% or more in six instances (cases 2, 4B, 5, 7, 14, and 18). A decrease in hepatosplenomegaly and lymph node enlargement was observed in eight patients. Excellent objective improvement was observed in three instances (cases 4B, 12, and 14), good objective improvement in eight (cases 2, 4A, 5, 6, 7, 8B, 11, and 18), and slight or no objective improvement in the remaining nine cases. Subjective improvement was less regular than objective improvement. More than half the patients who showed objective improvement reported an increase in general well-being and appetite and a decrease in fatigue and ability to return to some normal activities. In 3 instances (cases 7, 12, and 14) marked subjective improvement was reported, while in 5 instances (cases 4A, 4B, 5, 6, and 11) moderate subjective improvement was reported and there was none in 12. The average duration of remission in eight cases (cases 4A, 4B, 5, 7, 8B, 11, 12, and 14) in which the patient responded to therapy and lived more than two months was about five months.

toms. Established paralyses have been unaffected. In the majority of patients, 25 mg. given three or four times daily appeared to be sufficient to control symptoms, but in three patients a single 100-mg. dose was first followed by complete clinical remission. In one of the three, the effect of chlorpromazine during a subsequent mild relapse of pain was of relatively short duration. No definite evidence has been obtained that a reduced excretion of porphyrins or porphobilinogen is an early effect of chlorpromazine therapy. It is possible that the drug interrupts a vicious cycle, permitting a spontaneous remission to occur.

In two cases Rauwolfia alkaloid has been of value in maintenance therapy. In both instances there was absence of nervous symptoms when the patients were receiving the drug, and there was recurrence when the drug was withdrawn. The present experience indicates that chlorpromazine, in relation to other chemicals, is at least reasonably safe in cases of acute porphyria. There has been no suggestion that its use precipitates a relapse of the disease. It is the most consistently effective remedy thus far available for the pain and nervous manifestations.

CHLORAMBUCIL IN TREATMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA AND CERTAIN LYMPHOMAS

John E. Ultmann, M.D., George A. Hyman, M.D.
and
Alfred Gellhorn, M.D., New York

• *Chlorambucil was administered by mouth in doses ranging from 5 to 30 mg. daily for five to seven weeks, so than an average course amounted to 350 mg. Thirty patients were thus treated for lymphocytic leukemias and various lymphomas. In the largest group, namely, 18 patients with chronic lymphocytic leukemia, 3 patients obtained excellent results, in that the hemoglobin level and white blood cell count returned to normal, the differential count was significantly improved, and hepatosplenomegaly and lymph node enlargement disappeared. Eight other patients of this group obtained good results in that the white blood cell count fell, the hemoglobin level rose, the differential count improved, and the liver, spleen, and lymph nodes decreased in size. Results in cases of lymphocytic lymphosarcoma and Hodgkin's disease were less encouraging. In the dosages used, chlorambucil was practically without side-effects.*

In their systematic investigation of the carcinogenic and chemotherapeutic properties of the alkylating agents, Haddow and his associates of the Chester Beatty Research Institute in England[1] examined a variety of aliphatic and aromatic nitrogen mustards. In the course of their study, they found that certain aliphatic alkylating agents particularly depressed myelopoiesis. This lead to the development of busulfan (Myleran), which has been discussed extensively in recent articles.[2] Administration of certain aromatic alkylating agents, on the other hand, led to a specific decrease in circulating lymphocytes. One of these aromatic nitrogen mustards is chlorambucil [*p*-(di-2-chloroethyl) aminophenylbutyric acid], also called CB 1348. The *relationship* of chlorambucil to other alkylating agents is shown in the figure. The physical and chemical properties of this agent have been described.[3] Haddow found that in rats chlorambucil inhibited Walker carcinoma 256 in doses that had only slight effect on the white blood cell count of normal rats.[4] Elson[1a] as well as Bollag[5] demonstrated that large doses had a profound effect on the lymphocytes of the rat, causing a rapid fall without substantial influence on the granulocytes. This apparent "specificity" prompted investigation of the use of this drug in those conditions in man in which an abnormal proliferation of lymphocytes is found.

therapy. On the other hand, severe leukopenia and thrombocytopenia did occur in one patient who had giant follicular lymphoma and who had been treated with radiotherapy, even though she received a relatively small dose of chlorambucil (case 1, table 3). In another patient, a man with chronic lymphocytic leukemia (case 8B, table 2), administration of chlorambucil brought about such a rapid decrease in the number of lymphocytes that hyperuricemia resulted. The patient drank an insufficient amount of water during hard manual labor on a very hot day, which resulted in dehydration, oliguria, and, subsequently, transient anuria that was shown to be due to formation of uric acid crystals. The patient recovered after a stormy course and his condition is now in remission.

Autopsies.—Of the 30 patients treated, 10 have died and autopsies have been performed on 5 (cases 1 and 15, table 2; cases 2, 4, and 10, table 3). In findings of all autopsies, there was evidence of active disease with involvement of lymph nodes, viscera, and other organs. On microscopic examination, characteristic neoplastic cells were easily recognized and no evidence of cytotoxicity was described. Gross examination as well as microscopic study showed no evidence of hepatic or renal disease that could be attributed to drug toxicity. Hypoplastic marrow was described in three instances, but in two cases there was diffuse replacement by tumor tissue.

Comment

Galton and others[6] reported recently on their experience with chlorambucil. They treated 62 patients suffering from malignant lymphomas with a dosage schedule similar to that used in our study. They obtained excellent remissions in 4 of 23 patients with Hodgkin's disease, in 7 of 12 patients with lymphocytic lymphoma, in 4 of 8 with chronic lymphocytic leukemia, and 5 of 6 with follicular lymphoma. They noted that side-effects were fewer than those noted in therapy with nitrogen mustard or triethylene melamine (TEM), and they felt that profound marrow depression was directly related to the dosage and was therefore avoidable. Prossor and co-workers [7] of the Westminster Hospital in London employed chlorambucil in a total of 39 cases, including 24 of Hodgkin's disease, 2 of lymphosarcoma, 3 of lymphocytic leukemia, 2 of granulocytic leukemia, 4 of plasma cell myeloma, and 3 of generalized carcinomatosis. It was the feeling of the authors that "good temporary palliation" was achieved in a good proportion of patients, particularly those with lymphoma. No further details are given in this preliminary report.

It is our impression that chlorambucil is of beneficial effect in certain patients with chronic lymphocytic leukemia. Decreases in the white blood cell count, some reversal of the differential count, improvement of hemoglobin level, and some decrease in hepatosplenomegaly and lymph node enlargement can be expected in about two-thirds of the cases. This coincides with improvement in the well-being of the patient in about one-half of the cases.

A comparison of results in this series with those obtained by other modes of therapy is difficult. It has been stated repeatedly that radiotherapy decreases morbidity in chronic lymphocytic leukemia with no effect on survival time. Most statistical analyses, however, do not deal with remission rate and duration of remissions. An analysis of the duration of remission with techniques of titrated total body radiation by external x-ray [8] or radiophosphorus (P^{32}) [8b] is impossible, because repeated small doses are administered to keep the patient in constant remission. In chronic lymphocytic leukemia, use of urethan reduces the abnormal blood cell count, but maintenance therapy is necessary, and when administration is discontinued the count rises promptly.[9] In some cases, remissions of three and one-half to six months have been observed.[10]

Triethylene melamine is useful in chronic lymphocytic leukemia since small doses produce improvement lasting three to five months,[11] but rarely longer.[12] Triethylene melamine therapy may, however, be hazardous, particularly in patients with low platelet counts.[11] With chlorambucil therapy, remissions of three to six months may occur in the conditions of those patients who respond.

In those patients in whom thrombocytopenia is an initial finding, chlorambucil appears to be of particular usefulness. Galton [6] has pointed out that depression in platelet level is rarely serious. In the present series of patients with chronic lymphocytic leukemia, half had initial platelet counts below 100,000 per cubic millimeter, although none had overt hemorrhagic phenomena. With effective courses of chlorambucil therapy, the platelet levels did not fall significantly in any of these patients.

The wide range of doses required by different patients is of interest. Of the nine patients who had chronic lymphocytic leukemia and who did not respond, two patients showed no significant response after the administration of 12 and 13 mg. per kilogram of body weight of chlorambucil given over 65 and 45 days respectively. On the other hand, in certain patients a marked fall in white blood cell counts occurred with doses of as little as 0.7 and 1 mg. per kilogram of body weight given over 6 and 10 days respectively. The cause for this variability in response to therapy is not clear. It may be due to differences in gastric acidity, absorption, or utilization. The two patients showing no response to large doses of chlorambucil had moderately low gastric acidity. The period of therapy required with chlorambucil is considerably longer than with triethylene melamine. Thus, in one patient, the administration of single doses of triethylene melamine resulted in remissions of one year on two occasions. In contrast, therapy with chlorambucil required nearly two months to induce a similar response in the same patient.

Our experience with chlorambucil therapy in the other lymphomas has not been extensive. Patients with lymphocytic lymphosarcoma appear to respond less well than those with chronic lymphocytic leukemia. The response to this therapy in patients with Hodgkin's disease is not as good as to therapy with methyl-bis (β-chloroethyl)-amine or triethylene melamine, although we have observed one patient in whom significant improvement occurred with chlorambucil therapy after resistance to other nitrogen mustards had developed. These results are similar to those reported in the larger series of Galton.[6]

Summary

Thirty patients were treated with chlorambucil [*p*-(di-2-chloroethyl)aminophenylbutyric acid] (CB 1348), an aromatic nitrogen mustard. Satisfactory responses were obtained in patients with chronic lymphocytic leukemia; the drug appears to be of particular usefulness when patients with this disease also have moderate thrombocytopenia. Chlorambucil was found to be of less value in lymphocytic lymphosarcoma and Hodgkin's disease. We have found the drug to be relatively free of side-effects when administered orally. Effective therapeutic doses cause bone marrow damage only rarely.

630 W. 168th St. (32) (Dr. Ultmann).

This work was supported in part by grants from the National Cancer Institute of the U. S. Public Health Service and in part by the Hyman Goldburg Fund.

The chlorambucil used in this study was supplied in part by Dr. Alexander Haddow and Dr. D. A. G. Galton and in part by Dr. Donald Searle of Burroughs Wellcome & Company, Inc., Tuckahoe, N. Y.

Jane E. Harvey and Ana Tiburcio gave technical assistance.

HIATAL HERNIA COMPLEX

HIATAL HERNIA, PEPTIC ESOPHAGITIS, MALLORY-WEISS SYNDROME, HEMORRHAGE AND ANEMIA, AND MARGINAL ESOPHAGOGASTRIC ULCER

Felix G. Fleischner, M.D., Boston

• *The junction of the esophagus and stomach is normally closed except during deglutition, but the structures and mechanics involved in the closure are poorly understood. Roentgenologic observations indicate that the lowermost segment of the esophagus, over a length of 2 to 4 cm., constitutes a functional internal sphincter and that the muscle bundles about the hiatus of the diaphragm constitute an external sphincter*

Dislocation of these sphincters in the presence of a hiatal hernia may disturb the closing mechanism at the cardia and permit reflux of gastric juice into the esophagus. The ensuing peptic esophagitis causes most of the symptoms usually ascribed to the hiatal hernia. Further complications are acute lacerations at the esophagogastric junction with severe hemorrhage following vomiting, the peptic marginal ulcer sometimes converted from these lacerations by chronic peptic irritation, and slowly developing anemia. The close interrelation of these conditions to each other and to the disturbed sphincteric closure in the presence of a hiatal hernia is illustrated by roentgen observations, diagrams, and a report on a patient with fatal Mallory-Weiss lacerations.

Although large hiatal hernias had been observed earlier, small and medium-sized hiatal hernias became recognized with increasing frequency in the 1920's. To Carman and Fineman[1] in the United States and to Akerlund[2] in Stockholm goes the credit for having brought the hiatal hernia to our clinical awareness. Harrington,[3] Reich,[4] Anders,[5] and others have contributed much to our knowledge of anatomy and physiology of the cardia. The "epiphrenal syndrome" was described by von Bergmann, and the association of hiatal hernia and anemia was also early pointed out by Öhnell. "Peptic esophagitis" was another new concept. Earlier observations in the esophagus, made at autopsy, had been interpreted as postmortem digestion by regurgitated gastric juice. Hamperl[5] described the gross and microscopic pathological features of peptic esophagitis as recently as 1934, and Winkelstein[6] in 1935 independently reported "Peptic Esophagitis: A New Clinical Entity." Subsequent contributions have come from Allison, Johnstone,[7] and Barrett,[8] in England. Mallory and Weiss[9] observed longitudinal lacerations at the cardia in patients who died of upper gastrointestinal hemorrhage. Gastric resection may control massive upper gastrointestinal bleeding of unknown origin.

Most of these observations are rather new, and some of them seem quite unrelated. An attempt will be made here to correlate them and to establish their clinical significance. It appears advisable to commence with a brief discussion of the anatomy and physiology of the cardia as I see them, since there is no full agreement on this subject. The difficulties are increased by a confusing nomenclature. My concept is based on the literature, my own observations, and joint observations with colleagues in pathology and surgery.

Location of the Cardia

The tubular gullet enters the bag-like stomach at a point that is marked, at the greater curvature, by a fairly constant indentation, the incisura cardiaca. There is no corresponding landmark at the lesser curvature or the inner mucosal surface. The opening

---

From the departments of radiology, Beth Israel Hospital and Harvard Medical School.

Read before the Ninth Clinical Meeting of the American Medical Association, Boston, Nov. 29, 1955 of the funneling lower end of the tube is called the cardiac opening or anatomic cardia. The funnel-shaped structure extending from the diaphragm to the cardiac opening has always been called the abdominal portion of the esophagus, and the functional separation of esophagus and stomach has been placed at the cardiac opening. Many observations of the past 30 years, however, make this concept untenable. No intrinsic occlusive mechanism has ever been observed at the anatomic cardia. Some authors believe that the oblique implantation of the tubular structure into the stomach provides a flap with a valve-like action. The roentgenologic morphology of this "cardiac valve" has been thoroughly explored by Jutras, Levrier, and Longtin. Neither roentgenologic nor esophagoscopic observation has demonstrated any occluding mechanism at this level. The great variability in the mode of formation and depth of the incisura cardiaca also militates against this hypothesis.

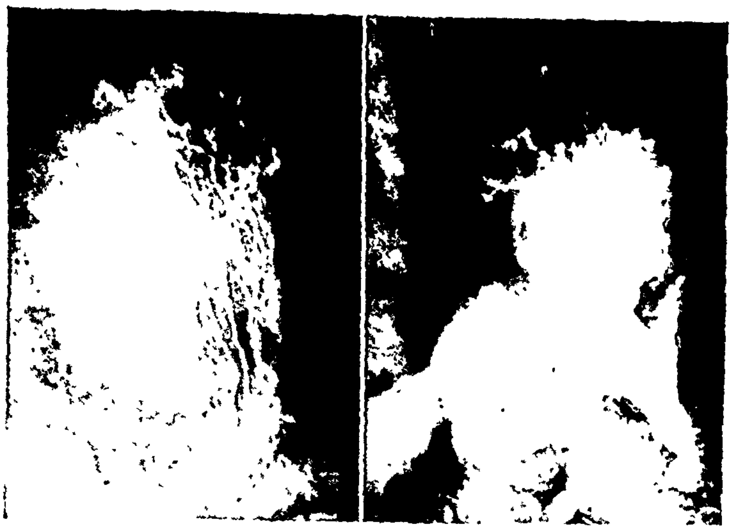

Fig. 1.—"Cardiac antrum of stomach." Two examples of stomachs (roentgenograms taken with patients in prone position but turned so that reader faces patient) in which barium-air contrast offers clear view of "abdominal portion of esophagus." In these instances this tubular or conical portion is lined by mucosa presenting the convoluted gastric rugal pattern, and the *visible occlusion is at the level of the diaphragm rather than at the* anatomic cardia, identified by the incisura cardiaca.

Reich's[4] work in 1927 with use of wax casts of the stomach provided one of the earliest hints that the physiological cardia, the functional occlusion between esophagus and stomach, might lie at the level of the diaphragm. Many other data point in this direction. Only the simplest roentgenologic observations shall be mentioned here. If we observe the swallowing act, with the subject in recumbent position, we may see the bolus pass down and come to a temporary stop just above the diaphragm. Then something opens and the barium slides down into the stomach. If we make the patient take a deep breath while the barium is just passing through, the barium column is broken by a wide band-like interruption that keeps the upper segment arrested for the time the inspiratory standstill is maintained. As soon as the diaphragm is relaxed, the barium resumes its flow in full width through the reopened straits. The level of this complete closure on deep inspiration is the same as that of the temporary stop or the slight narrowing of the barium shadow observed during quiet respiration. In addition to the known relation of onset of the swallowing act and respiration, there is also a well-harmonized interplay of the normal respiratory movement of the diaphragm and the activity of the lower portion of the esophagus and functional cardia. Of several related facts in the area of pathology, only the case of cardiospasm or achalasia of the esophagus may be mentioned here. The obstructing narrowing in this condition is always seen at the level of the esophageal hiatus of the diaphragm or above it, but never at the anatomic cardia.

Abdominal Portion of the Esophagus

The transition from the stratified squamous epithelium of the esophagus to the columnar gastric epithelium has been thought to occur at the anatomic cardia. In reality it is found somewhere between the level of the diaphragm and the cardiac opening. Furthermore, instead of a smooth circumferential line, this transition often consists of finger-like extensions of both mucosal structures interlacing with each other for a considerable distance. The funnel-shaped dilatation of the "esophagus" after its passage through the diaphragm may be lined wholly or in large part by gastric epithelium with cardiac glands. With the occluding mechanism between esophagus and stomach established at the level of the diaphragm, it seems reasonable to call the subdiaphragmatic part the cardiac antrum of the stomach, rather than the abdominal portion of the esophagus. Embryologic data also support this view.

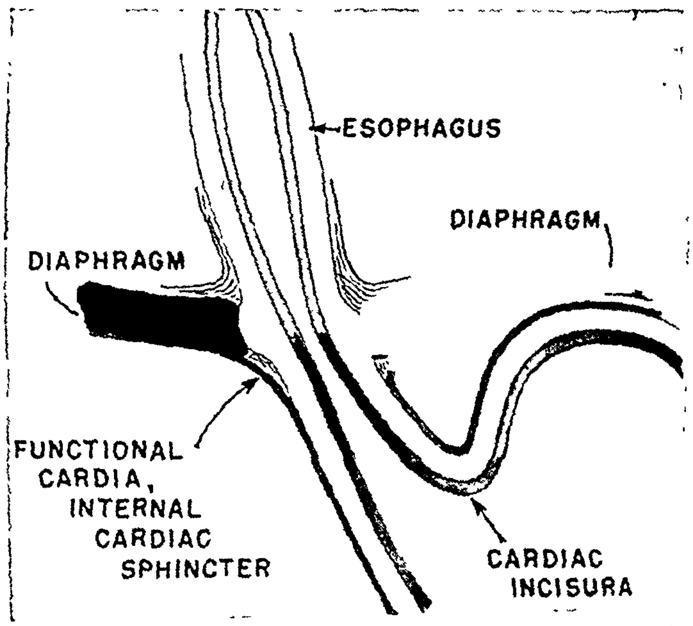

Fig. 2.—Diagram of normal cardiac region. Esophagus is anchored to rim of esophageal hiatus of diaphragm by fibers of phrenoesophageal ligament. Incisura cardiaca (*right lower arrow*) indicates site of "anatomic cardia." Diaphragm forms external sphincter of "functional cardia" (*left lower arrow*). Internal cardiac sphincter (see text) is indicated by the diagrammatically exaggerated swelling of muscularis propria of esophagus. Variable zone of transition from esophageal to gastric mucosa is kept black.

Roentgenologic observations conform with this new concept much better than with the traditional one.

Whenever a subdiaphragmatic funnel-shaped structure can be visualized—this is rarely possible with a completely distended fundus—the lining mucosa usually presents a rugal pattern similar to that of the stomach rather than to that of the esophagus (fig. 1). The incisura cardiaca, marking the cardiac opening, is formed by the oblique fibers separated from the circular fibers in the muscular coat of the stomach. The depth of the incisura cardiaca varies from subject to subject and undergoes functional changes in a single individual. If the stomach is dilated, the incisura is blunted and may completely disappear, and the so-called abdominal portion of the esophagus becomes absorbed by the stomach (Palmer[10]). This brief discussion may be concluded with Allison's statement based on esophagoscopic observation that there is in the normal subject "in life no such thing as the abdominal esophagus" (fig. 2).

Functional (or Physiological) Cardia

I recommend application of the term functional cardia as opposed to the "anatomic cardia" of old tradition. One may use the term esophagogastric mucosal junction for the transition of the two types of epithelium. Unfortunately, the abbreviated term esophagogastric junction has been used alternately for both the epithelial transition and the closing mechanism, without any explanation or definition, as if the epithelial transition was necessarily located at, or had anything to do with, the functional closure.

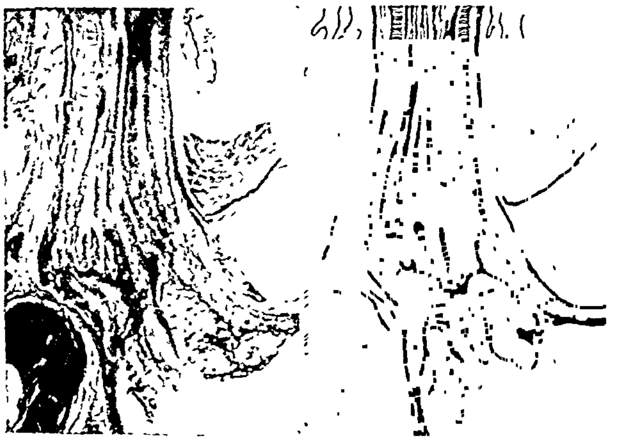

Fig. 3.—Coronal, longitudinal section through lower portion of esophagus, cardia, and diaphragm with explanatory diagram (from holoptic section). Stumps of diaphragm embrace intestine on either side. Transition from slender longitudinal mucosal folds of esophagus to thicker convoluted gastric folds at hiatal level is clearly seen. Circular and longitudinal layers of muscularis propria of esophagus are becoming slightly thicker at and below hiatus (from Reich, L.: Antrum Cardiacum, Incisura Cardiaca und Gasblase des Magens, *Fortschr. a. d. Geb. d. Rontgenstrahlen [Tagungshft.]* 56:37, 1937).

The circular layer of the muscularis propria of the esophagus is rather strong in the lowermost portion. Most anatomists do not find a morphologically identifiable ring-shaped sphincter (some mammals, e. g., the porpoise, have a quick-acting cardiac sphincter); Laimer and Lerche are exceptions. There is general agreement, however, that the lowermost portion of the esophagus, called vestibule by some, has a sphincteric capacity over a length of 2 to 4 cm., and it is practical to call this the "internal sphincter" of the physiological cardia. Very little has been written in regard to the longitudinal muscle, although it plays an integral part in the transport of ingesta in any hollow viscus. In particular, contraction of the longitudinal muscle acts to pull up the cardiac end of the stomach. There is good reason to assume that the mucous membrane also plays a part, both passively, by heaping up during narrowing of the lumen, and actively, by the controlling muscularis mucosae. Hardly any controversy exists about the "external sphincter" provided by the diaphragmatic muscle bundles that form the hiatus, the "pinchcock action" of the diaphragm (Jackson; Reich[4]) (fig. 3).

Esophageal Hiatus

The esophageal hiatus of the diaphragm is formed in man by fasciculi of the right crus; only rarely do bundles of the left crus cross to take part in it. Fibers of the fascia from the undersurface of the diaphragm and probably also some muscular fibers of the diaphragm merge with the muscular tube of the esophagus in a funnel-like fashion to form the phrenoesophageal ligament, which anchors the esophagus to the rim of the hiatus. The suspension of the esophagus within the hiatal ring of the diaphragm provides for rather wide lengthwise movements of the esophagus. We make ample use of this movability during breathing, during filling and emptying of the stomach, and in changing from supine to erect position. This flexibility is the main reason why it is so difficult to establish the topographic relations at the esophageal hiatus by the routine method of postmortem dissection and why it is often difficult or impossible at death to establish the antemortem presence of a small or medium-sized nonincarcerated hiatal hernia. Excursions of the esophagus may become excessive in abnormal conditions: severe cicatricial esophagitis or a posterior mediastinal tumor may pull the functional cardia and a portion of the stomach upward; pneumoperitoneum in the erect position allows liver, spleen, and stomach to fall away from the diaphragm, pulling a sizable portion of the esophagus down into the abdomen, to slip back when the subject lies down.

In addition to the up and down movement of the esophagus as a whole, in relation to the diaphragm, or of the diaphragm in relation to the esophagus, the mucosal tube moves within the muscular tube of the esophagus. This motion was suggested early by fluoroscopic observations (Reich[4]) and has been confirmed and amplified by Allison's roentgenologic observations of silver clips implanted through the esophagoscope in the mucous membrane at the esophagogastric epithelial transition. Additional information has been obtained in the experimental animal by observing metal balls attached to the outside of the esophagus (Nauta[11]) and by endoscopy through a gastrostomy.

The loose submucosa permits considerable up and down movement of the mucous membrane within the muscular tube of the esophagus. *Spontaneous up and* down migration of limited amplitude occurs in the resting organ, presumably controlled by longitudinal contractions of the muscularis mucosae. During deglutition the mucosa moves upward to meet the bolus, receives it, carries it down, and while ejecting it everts into the stomach, forming a rosette-like protrusion (comparable with visible movements of the anus of a defecating horse) (Nauta [11]). This is sometimes seen as a lobulated soft tissue mass protruding into the right upper corner of the gas-filled fundus. A small pocket of gastric mucosa quite commonly appears above the diaphragm while the bolus passes, to disappear immediately afterward (Palmer [10]).

With this wide range of normal change in position, it would be arbitrary and probably incorrect to state that a certain level of the esophagus or mucous membrane is normally situated at the level of the diaphragm. Furthermore, the transition from the normal condition to a hiatal hernia is obviously gradual. With such fluctuations in function and time, the extreme reluctance of some to diagnose a small hiatal hernia and the criticism of others that hernias are diagnosed too often lose their meaning. A small hiatal hernia is frequently a physiological borderline situation without clinical significance; it may, however, have the inherent potentiality of becoming larger and significant.

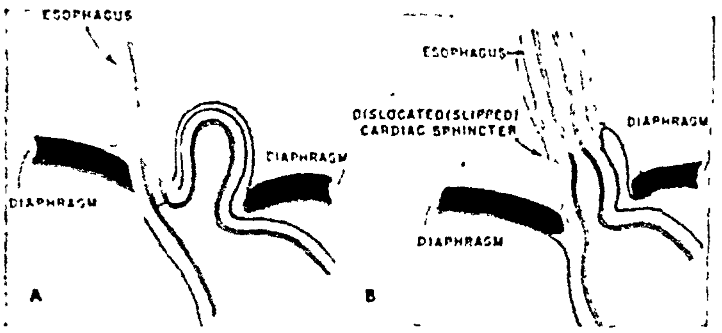

Fig. 4.—*A*, paraesophageal, or rolling hiatal, hernia. Esophagus is assumed to be fixed at right (posterior) portion of hiatus, while fundus of stomach has herniated along it through widened hiatus. *B*, axial, concentric, or sliding hiatal hernia. Esophageal hiatus is usually widened. Esophagus and adjacent portion of stomach have slipped upward, resulting in local dissociation of the internal (esophageal) and external (diaphragmatic) cardiac sphincter. Esophagus usually is shortened and contracted, but sometimes is of normal length and tortuous. A peritoneal hernial sack sur*rounds herniated stomach only partially*, according to most authors—therefore, sliding hiatal hernia. Dislocated internal cardiac sphincter *(arrow)* deprived of support by its external partner, the diaphragm, often becomes incompetent.

Hiatal Hernia

Among the factors responsible for the formation of a hiatal hernia, only those that bear on the problems under discussion here will be briefly listed. The width of the esophageal hiatus varies greatly in normal conditions. Harrington examined the hiatus during 1,000 consecutive laparotomies. In 55% the hiatal rim surrounded the esophagus tightly; in 35% one finger could be inserted between the esophagus and the margin of the hiatus; and in 10% two or three fingers could be inserted. The hiatus seems to become wider with increasing age. As at any other site of abdominal hernias, an increased width of the opening is not in itself pathological; however, it favors herniation. The hiatal opening is always found wider than normal when hiatal hernias have formed.

Individual variations in strength and tightness of the phrenoesophageal ligament may well be assumed. The suspensory apparatus loosens in the course of debilitating disease and advancing age. Increased abdominal pressure plays a role as in other hernias. Transient or persisting hiatal hernia occurs in the presence of ascites, large abdominal tumors, late pregnancy, and experimentally increased intra-abdominal pressure. *Vomiting and abdominal injury* with bracing of the trunk may induce hiatal hernia by sudden increase of the intra-abdominal pressure in predisposed subjects.

If one omits, for the purposes of this discussion, large hernias where the greater part of the stomach lies in the chest and considers only small and medium-sized hernias, one usually distinguishes two types: (1) those in which the esophagus and stomach have slipped through the hiatus as a whole in an axial fashion, therefore axial or concentric hernia or, because of the incomplete peritoneal investment, sliding hernia, and (2) those in which the fundus of the stomach seems to have slipped upward along the esophagus, therefore paraesophageal or rolling hernia (parahiatal hernia [Sweet]). *The slipping up and down, however, with change of position or degree of filling, is not designated by the term sliding hernia referred to in the first type.* The surgical term, sliding hernia, generally indicates a hernia where the herniated viscus is invested by peritoneum only for a portion of its circumference This is the case in many axial hernias; it is not clear however, whether this is the rule in all cases (Allison Harrington). *While this feature is important for the* surgical handling of a given case, it cannot be predicted in detail. It is, therefore, preferable to designate these hernias with the unassuming descriptive term "axial or concentric hernia" in logical antithesis to the paraesophageal type. In both types one can usually recognize the dislocated internal cardiac sphincter (fig. 4). Both types may be spontaneously reducible or permanently incarcerated. A small or medium-sized hernia visible in recumbent position may change its size considerably or disappear in the erect position.

In the paraesophageal hernia the anchorage of the esophagus to the right and posterior portion of the hiatal ring appears to be more secure in many individuals than at the remainder of its circumference. An outpouching of the diaphragmatic peritoneum between esophagus and hiatal rim is believed to precede the prolapse of a portion of the gastric fundus. Vestigial peritoneal clefts may play a role in certain instances. These hernias, except for their esophageal part, are usually completely covered by peritoneum.

The characteristic indentation between esophagus and herniated gastric pouch, in my opinion, represents the persistent incisura cardiaca, a structural feature of the stomach, not a fasciculus of diaphragmatic muscle (Sweet). In the paraesophageal hernia the incisura cardiaca is preserved; in the axial type it is effaced. Occasionally the same small hernia may seem axial in type with a low esophageal ring when filled, distended, and spot-filmed during inspiration, while it appears paraesophageal with marked indentation when roentgenographed fairly empty, collapsed, during expiration.

In both types of hernias a circular narrowing 2 cm. or more above the diaphragm is usually seen. This irregular narrowing changes in width and may disappear when the esophagus widens during the passage of barium, to reappear at the same place when the bolus has passed. The mucosa below this narrowing usually has the pattern of gastric folds. On roentgenologic and gastroscopic evidence this circular narrowing represents the dislocated internal sphincter of the functional cardia. This slipped cardiac sphincter is often continent under otherwise normal conditions. This weak sphincter, however, deprived by its dislocation of the support of the external sphincter, easily becomes incompetent, permitting reflux of gastric content into the esophagus. In rare instances the slipped sphincter becomes spastic and causes dysphagia. The "lower esophageal ring" of Schatzki and Gary,[12] and Ingelfinger and Kramer,[13] is caused, in my opinion, by sphincteric action of the muscularis mucosae at the level of the slipped internal sphincter in response to superficial ulceration there, thus elevating and molding this diaphragm-like mucosal fold. In the irreversible case it soon develops into submucosal inflammation and a submucosal fibrotic ring, resembling the fixed diaphragm-like mucosal fold encountered with peptic ulcers in the gastric antrum.

Peptic Esophagitis

The discussion of peptic esophagitis in this context, as well as the discussion on marginal ulcer in a later section, is necessarily aphoristically brief. The reader is referred for comprehensive information to Palmer, Schmidt, and Barrett.

Heartburn has been believed for a long time to be caused by reflux of acid gastric contents into the esophagus. However, this was considered rather a layman's interpretation, and scientific medicine expressed itself very cautiously on this subject. The clinical symptoms of hiatal hernia have been explained, until very recently, in various ways, often without proper consideration of reflux of gastric juice and peptic esophagitis. While Robins and Jankelson observed gastroesophageal reflux first in 1926, Winkelstein,[6] Allison and Johnstone, and Barrett have established the fact of rather frequent reflux of gastric content into the esophagus in the presence of a hiatal hernia and have convincingly demonstrated that the consequent peptic esophagitis is the source of most clinical symptoms. Guided independently by similar considerations for many years, I have been carefully watching the presence or absence of gastric reflux in every instance of hiatal hernia and am convinced of the overwhelming role of peptic irritation of the esophageal mucosa. It must be noted, however, that some authors do not accept this view.

Our knowledge of peptic esophagitis is a recent acquisition. The pathologists, overcautiously, had interpreted the changes found in the esophagus as postmortem digestion caused by regurgitant gastric juice. Though the chronic peptic ulcer of the lower portion of the esophagus had been recognized for a long time, the first modern pathological description of peptic (erosive) esophagitis was published by Hamperl[5] in 1934. The welling up of gastric juice above the slipped cardiac sphincter can be readily seen by esophagoscopy; general inflammation and longitudinal superficial ulcerations are regular findings in instances of symptomatic hiatal hernia (Schmidt; Barrett; Benedict). The roentgenologic observations closely parallel this experience. With small and medium-sized hernias (while examining the subject in recumbent position, the best position being prone with the left side elevated or supine with the right side elevated) we may observe that barium flows back from the stomach into the esophagus. Filling of a herniated pouch in itself does not constitute abnormal reflux. Only backflow into the esophagus reveals incompetence of the sphincter and abnormal reflux. With marked incompetency of the slipped internal sphincter, this reflux can be observed quite regularly. In other cases one may observe it only once or twice during an examination. Competency and incompetency of the sphincter are functional conditions that may change in degree from time to time.

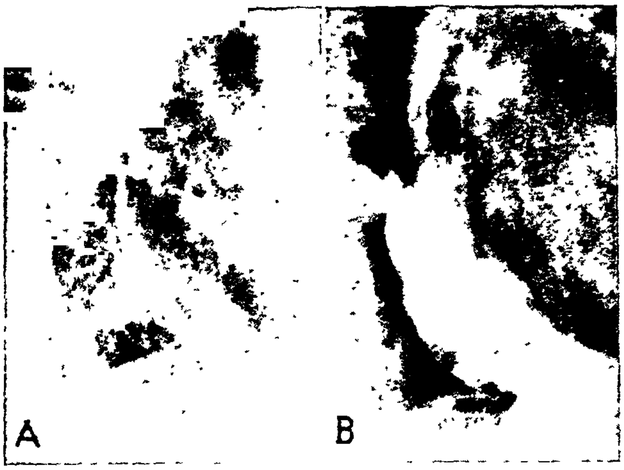

Fig. 5.—Roentgenograms of woman, aged 69, with clinical evidence of rather severe peptic esophagitis. Small, axial hiatal hernia with reflux of gastric content into esophagus, in recumbent position. *A*, small hernia, partially filled with barium. At upper end of this gastric pouch is site of slipped internal cardiac sphincter; above this is slightly irregular mucosal relief of lower portion of esophagus—esophagitis. *B*, spontaneous reflux of gastric content (barium) into esophagus.

The fact that regurgitation of gastric juice is not necessarily a constant phenomenon is best illustrated by an observation of Johnstone. A woman of middle age had a classic history of peptic esophagitis. At the first roentgenologic examination, a hiatal hernia with reflux was found. At a second and third examination they could not be seen. When the patient reported that symptoms were worst when she was tired, another examination was carried out in the evening, after a full day's work. This conclusively showed a small hiatal hernia and free reflux, which finding was confirmed at operation a few days later. The explanation apparently lies in disturbed coordination and in muscular fatigue.

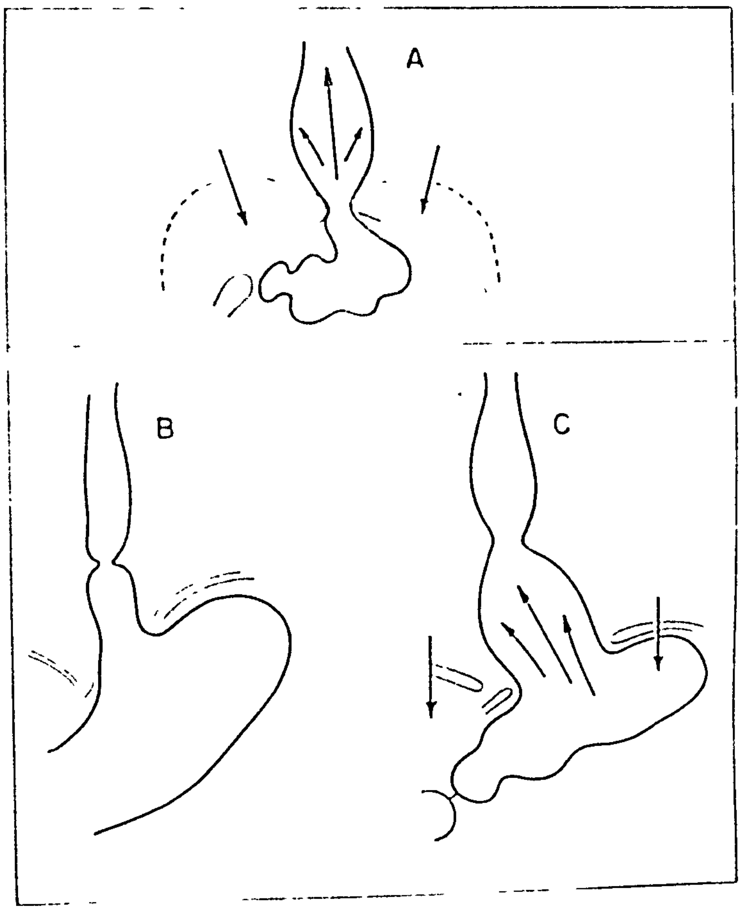

Fig. 6.—A, diagram to explain interaction of forces leading to spontaneous rupture of esophagus by vehement vomiting (after S. A. Mackler[16]). B, tracing of roentgenogram of an axial hernia. C, my concept of how, in the presence of such a hernia, interaction of anatomic conditions and forces during vomiting may cause mucosal laceration or complete rupture of esophageal wall (see text).

While gastric reflux usually occurs when the patient is in the recumbent position or stooping over and is of moderate degree, there are a few instances where the patient reports a sudden choking sensation. Here one may observe that, with a sudden inspiratory or expiratory movement of the diaphragm, a large amount of fluid is ejected into the widening esophagus. These patients have completely lost the sphincteric control at the esophagogastric junction.

As with peptic ulceration in general, the severity of peptic esophagitis in a given case is not solely dictated by the strength of the gastric juice and the frequency of its backflow but is also determined by the protective mechanisms of the body, the lack of which is usually described as "ulcer diathesis." In this connection, it may be noted that many instances of peptic esophagitis are associated with duodenal ulcer, suggesting that, with the accompanying hyperacidity, the regurgitant gastric juice becomes more injurious to the esophageal mucosa or that both the duodenal ulcer and peptic esophagitis are coordinated manifestations of an ulcer diathesis. Every bearer of a hiatal hernia is a potential candidate for gastric reflux and peptic esophagitis. I have observed gross reflux only rarely in the absence of a hiatal hernia.

In the newborn infant, incompetence of the physiological cardia is not uncommon; it is known as chalasia of the cardia (Neuhauser and Berenberg[14]). Apparently not all children are born with full mastery of the complicated coordination that makes for control of the cardia. Hiatal hernias, even of considerable size, have been observed in infants (Neuhauser; Silverman[15]). It seems to me that the persistence of these long tubular hernias, acquired in infancy, is the substratum of the baffling condition called by some "esophagus lined by gastric mucosa" (Allison).

The roentgenologic observation of gastric reflux reveals incompetence of the cardiac sphincter mechanism and potential irritation of the esophageal mucosa (fig. 5). Superficial irritation of the esophageal mucosa usually does not manifest itself roentgenologically. In more advanced instances of esophagitis, however, mucosal swelling and ulcerations become obvious. Minor and major irregularities, widening of folds and irregular contours, are seen instead of the perfectly parallel longitudinal folds of the normal esophagus. Only in very rare instances have I found it difficult to distinguish these irregularities of severe esophagitis from the pattern of esophageal varices.

Severe esophagitis with extensive ulceration, deep fibrosis, and muscular hypertrophy leads to extensive stricture and lengthwise shrinking of the esophagus. Etiological factors other than hiatal hernia may contribute, i. e., operations under general anesthesia, debilitating disease, extended forced bed rest, the extended use of a gastric tube, chronic severe vomiting, the early and late stages of pregnancy, and delivery.

It appears that fair agreement has been reached in the last few years concerning the features and theories of the hiatal hernia complex discussed so far. The situation, however, becomes more controversial and even enigmatic when we approach the chronic peptic ulcer or marginal ulcer of the esophagus, hemorrhage and anemia associated with hiatal hernia, and the Mallory-Weiss syndrome.

Mallory-Weiss Syndrome

Mallory and Weiss[9] observed longitudinal mucosal lacerations in the cardiac portion of the stomach at autopsy in patients with fatal hemorrhage and incriminated the preceding retching and vomiting as the main causative factor. Among the first reported cases, alcoholism was prevalent; in a later series, however, this was not the case, and the authors considered alcoholism merely as a factor initiating gastritis and vomiting. In three of the four cases of the first series, the mucosal tears were limited to the gastric side, extending close to the border of the esophagus; only in the fourth instance did the upper quarter of the tear extend into the esophagus. In the later series the tears appear to straddle the esophagogastric mucosal junction fairly evenly. Mallory and Weiss concluded from the large number of patients with the identical clinical syndrome who recovered spontaneously that some of these lesions must have a strong tendency to heal. However, they also considered the possibility that the lacerations might lead to chronic peptic ulcers in some instances.

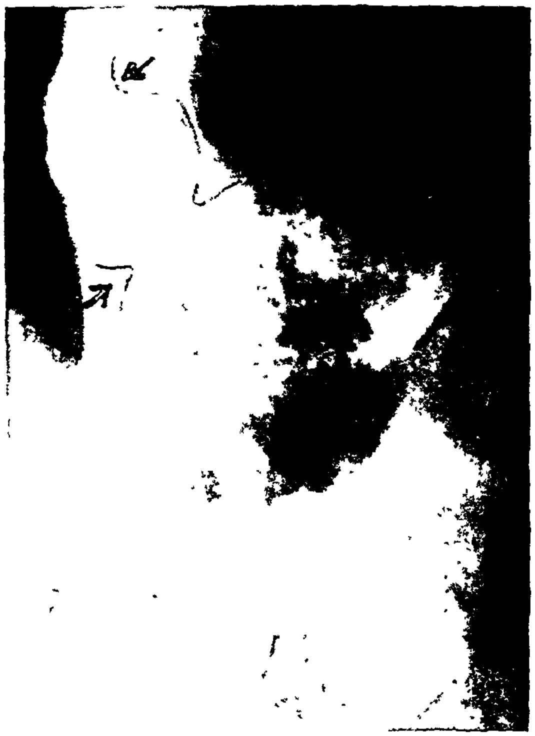

Fig. 7.—Emergency examination of esophagus and stomach of severely bleeding patient in supine position (case report). Medium-sized hiatal hernia, wide esophageal hiatus, and massive flow of barium from esophagus to stomach and from stomach to esophagus were observed. Lower arrow points to widened esophageal hiatus of diaphragm, upper arrow, to patulous slipped internal cardiac sphincter in a moment of massive gastroesophageal reflux.

While the pathological findings and clinical coordination with vomiting in this syndrome are well understood, difficulties still exist in visualizing the pathomechanics of the process. These difficulties are analogous to those encountered with the explanation of spontaneous rupture of the esophagus. In order to explain the situation, a diagram adapted from Mackler's[16] study of spontaneous rupture of the esophagus may be used (fig. 6).

Vomiting is understood to consist of a succession of coordinated events: inspiratory standstill, contraction of the gastric antrum forcing its contents toward the fundus, contraction of the abdominal muscles and diaphragm, and ejection of gastric content through the relaxed cardiac sphincter. From fluoroscopy and cineroentgenographic recordings, we are familiar with the ballooning of the lowermost portion of the esophagus during the act of vomiting. One may wonder, however, how a sufficient pressure can be built up to tear the lower portion of the esophagus in the absence of an additional obstruction in the upper portion. The esophagus is filled during the act of vomiting through the relatively narrow cardia, and the tear of spontaneous rupture is always found in the lowermost portion of the esophagus, sometimes extending below the hiatal ring. In complete ruptures the gross distortion of the tissues found at operation or autopsy interferes with detailed study of mode and site of origin. It is reasonable to consider Mallory-Weiss lacerations as incomplete ruptures of the esophageal wall, extending through mucosa and submucosa. If one applies Mackler's diagram to Mallory-Weiss lacerations, it is difficult to understand why a tear should occur in the cardiac portion of the stomach while the stomach is protected against overdistention by the elevated surrounding abdominal pressure. These difficulties, however, may be resolved if we follow the events during vomiting in the presence of a hiatal hernia.

First, the esophageal hiatus is usually wide whenever a hernia exists. Thus, the force of the jet of the ejected gastric contents would not be broken at the hiatal level, as it would in the presence of a competent hiatal ring. Second, the herniated gastric pouch is surrounded by the low thoracic pressure. Against this, the combined pressures of the gastric convulsion and the forceful contractions of the diaphragm and abdominal muscles operate from the inside. Third, the slipped internal cardiac sphincter forms a strait above the hernia, thus adding to the building up of pressure within the hernia. Fourth, the slipped internal sphincter is a natural narrowing of the tube, and [illegible] ved from its normally protecting hiatal ring [illegible] able to vehement, sudden distentio

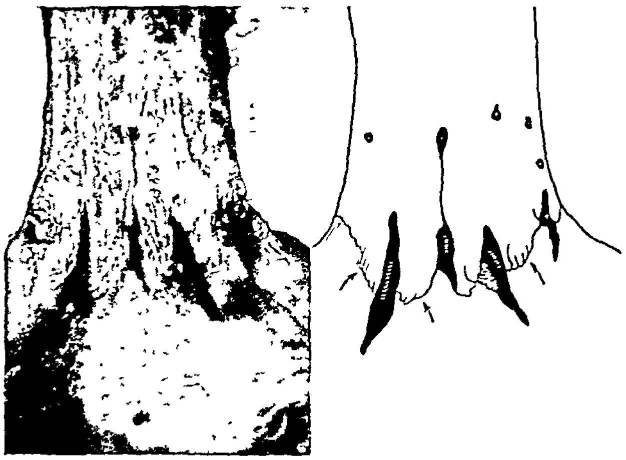

Fig. 8.—Postmortem specimen of the esophagogastric junction and explanatory diagram (patient in case report). There are four deep longitudinal lacerations of mucosa. Counting from left, (1) and (3) are very recent (microscopically) and (2) and (4) slightly older. From (2) a longitudinal recent scar extends into esophagus for about 2 cm., ending in a shallow ulcer. Four other small round ulcers are at about the same level in esophagus. Arrows indicate esophagogastric mucosal junction.

CLINICAL NOTES

DIATRIZOATE SODIUM, A NEW UROGRAPHIC CONTRAST MEDIUM

Everett E. Seedorf, M.D.
and
Eldon O. Bradfield, M.D., Temple, Texas

The history of excretory urography has been reviewed by Braasch and Emmett.[1] Sodium iodomethamate (Neo-Iopax) and iodopyracet injection (Diodrast) were the excretory urographic mediums used for many years in the United States, but these were replaced by sodium acetrizoate injection (Urokon) because of its capacity to produce urograms of better quality. In August, 1954, we were invited to assist in the investigation of a new urographic contrast medium, diatrizoate sodium (Hypaque). This medium is a highly water-soluble white crystalline solid that contains iodine (59.87%). The preparation is dispensed in ampuls containing 30 cc. of a 50% solution. In our initial investigation, we gave intravenous injections using these ampuls to 200 patients. Experience demonstrated that an injection time of three to five minutes was desirable. For each patient, the temperature, pulse rate, respiration rate, and blood pressure were recorded before and 15 minutes after an injection. In no instance was there an appreciable variation that could be attributed to the effect of the drug. In a small number of patients, however, a few reactions were observed. These symptoms were of about the same frequency and mild nature that we previously had observed from the routine use of sodium acetrizoate, using 20 to 25 cc. of a 30% concentration.

In our investigation of diatrizoate sodium, we immediately and consistently observed marked improvement in the quality of excretory urograms. Films exposed 5, 10, and 15 minutes after injection of the medium were graded as poor, fair, good, or excellent. Urograms were rated poor when there was no visualization or there were only faint shadows and fair when visualization of segments of the urinary system was unsatisfactory for diagnostic purposes. If there were faint but distinct outlines of the urinary organs or if sufficient segments were visualized so that a positive diagnosis could be made, the quality was considered good. When there were exceptionally bold outlines of the ureters as well as of the pelvis and calices of the kidneys and the urograms were equal to or superior to retrograde pyelograms, they were rated excellent.

Of urograms produced with sodium acetrizoate, using the 30% solution, only 38% were considered good or excellent; whereas 94% of the urograms produced with diatrizoate sodium, using ampuls containing 30 cc. of the 50% solution, were of good or excellent quality. Bold shadows were produced on the films exposed five minutes after injection of diatrizoate sodium. This medium appears to be excreted from the kidneys and ureters more slowly than sodium acetrizoate and, therefore, outlines the urinary excretory system more consistently and completely even on the films exposed 10 and 15 minutes after injection. This seems to be an important factor contributing to the higher percentage of good and excellent diagnostic urograms produced with diatrizoate sodium.

It was presumed that the superior quality of urograms produced by diatrizoate sodium probably was due to the *increased iodine content in the* dosage. By calculation, it is shown that approximately 6 gm. of iodine is contained in a 20-cc. dose of a 50% solution of diatrizoate sodium or a 30-cc. dose of a 30% solution of sodium acetrizoate. Accordingly, a group of 50 patients was given the reduced dosage of diatrizoate sodium (20 cc. of a 50% solution) and a second group of 50 patients was given the increased dosage of sodium acetrizoate (30 cc. of the 30% solution). In the first group, 84% of the urograms were graded good or excellent; in the second group, 86% of the urograms were of good or excellent quality.

TABLE 1.—*Incidence of Good and Excellent Urograms with Urographic Mediums*

	Sodium Acetrizoate	Diatrizoate Sodium	Diatrizoate Sodium	Sodium Acetrizoate	Sodium Acetrizoate
No. of patients	100	200	50	50	50
Dosage, cc.	20-25	30	20	30	25
Concentration, %	30	50	50	30	50
Amount of iodine, gm.	5	9	6	6	8.25
Good and excellent urograms, %	38	94	84	86	74

Shortly after we completed this comparative study, sodium acetrizoate became available in 25-cc. ampuls of the 50% concentration. We investigated this dosage in a series of 50 patients. By calculation, this dosage contains more iodine than the previously studied ampuls of sodium acetrizoate, but, upon grading of the urograms, only 74% produced by the newer concentration were classified within the good and excellent group. Table 1 illustrates the percentage of good and excellent urograms produced by the varying dosages and concentrations of sodium acetrizoate and of diatrizoate sodium.

Reactions were recorded after the injection of sodium acetrizoate (20 to 25 cc. of the 30% solution) and diatrizoate sodium (30 cc. of the 50% solution). As additional variations in dosage and concentration of these mediums were studied, observation of the side-effects was continued (table 2).

Occasionally, momentary nausea was observed after all dosages and concentrations of both drugs, but, if injection of the medium was interrupted for a short interval, the nausea soon abated. Vomiting seldom occurred. Of far greater significance was the occurrence of vein-cramping observed in 22% of the patients given sodium acetrizoate (25 cc. of the 50% solution). This symptom occurred more often with the 50% solution than with the 30% solution of this drug, probably because there was a greater concentration of the medium

---

From the Department of Radiology (Dr. Seedorf) and the Department of Urology (Dr. Bradfield) of the Scott and White Clinic. Dr. Seedorf is now in practice in Peoria, Ill.

Read before the Section on Radiology, Texas State Medical Association, Fort Worth, April 26, 1955.

within the fluid. Diatrizoate sodium was less prone to produce cramping of the veins. Itching sensations and urticaria were more common with sodium acetrizoate, but in most instances these symptoms disappeared within a few minutes after injection of the medium was completed. One patient experienced a short episode of sneezing after the administration of diatrizoate sodium.

TABLE 2.—*Incidence of Symptoms from Urographic Mediums*

	Sodium Acetrizoate	Diatrizoate Sodium	Diatrizoate Sodium	Sodium Acetrizoate	Sodium Acetrizoate
No. of patients	100	200	50	50	50
Dosage, cc.	25-30	30	20	30	25
Concentration, %	30	50	50	30	50
Side-effects, %					
Vein cramp	4	1	2	4	22
Nausea	4	6	8	4	18
Urticaria	2			4	10
Itching sensation	2	1	2	4	8
Flushing of skin		2	2	2	
Extreme pallor					2
Choking sensation				2	2
Sneezing		1			

Summary

From our study of urographic contrast mediums, we concluded that 30 cc. of a 50% solution of diatrizoate sodium (Hypaque) produces urograms of superior quality in a greater percentage of patients than can be obtained with 20 to 25 cc. of a 30% solution of sodium acetrizoate (Urokon) and slightly better urograms than were obtained with 25 cc. of a 50% solution of sodium acetrizoate. Probably because the medium is eliminated more slowly, the ureters are vizualized more clearly when diatrizoate sodium is used. There are few side-effects from diatrizoate sodium, particularly when the solution is not injected too rapidly. Objectionable reactions to sodium acetrizoate in doses of 25 cc. of the 50% concentration included a higher incidence of vein-cramping, nausea, and urticaria.

405 Main St., Peoria, Ill. (Dr. Seedorf).

The sodium acetrizoate used in this study was supplied as Urokon sodium, 50% solution, by Mallinckrodt Chemical Works, St. Louis, and the diatrizoate sodium was supplied as Hypaque by Winthrop-Stearns, Inc., New York.

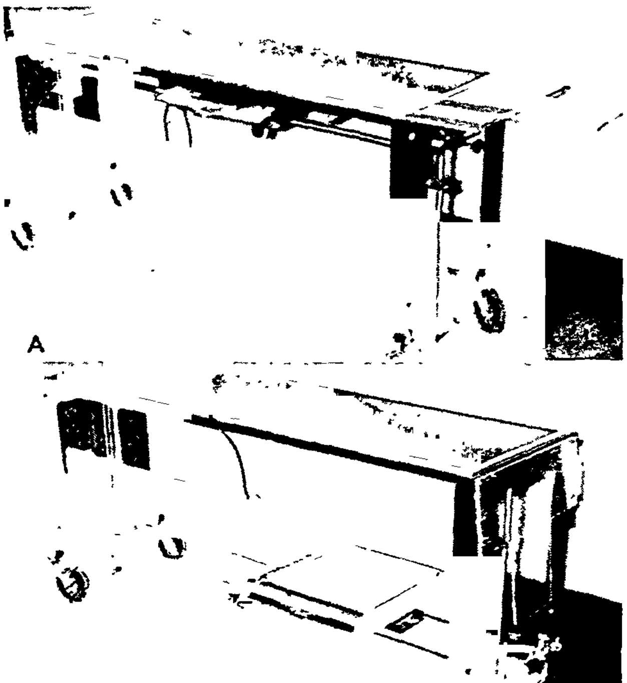
MOBILE RADIOTRANSLUCENT LITTER-TABLE WITH BUCKY DIAPHRAGM

Joseph Stein, M.D.
Ruth Hammerschlag, R.T.
and
Maxwell H. Poppel, M.D., New York

A mobile radiotranslucent litter-table with a Bucky diaphragm was constructed in our department as a result of a continually growing need for better radiographic procedures for bedside use and adaptable to the limitation of motion in seriously ill patients needing radiographic studies. Our table is also adapted for magnification techniques. We had investigated commercially available tables and had found nothing meeting our requirements. Several radiotranslucent tables obtainable on the market were of the type with supports under the table preventing use with an adjustable Bucky diaphragm stand. Our basic table is sufficiently strong to be safe for use with a mobile Bucky diaphragm stand, and it may be equipped with an attached Bucky diaphragm as we have done.

The table is constructed with a radiotranslucent top mounted on solid legs at the extreme ends and is equipped with lock wheels. For the comfort of some patients with back injuries, a radiotranslucent foam rubber pad covering the length of the table has been provided. At one end there is an extension for head radiography that allows for placement of a cassette for lateral skull projections without turning the patient. The metal trim around the table top permits mounting of magnetic cassette holders that aid in obtaining difficult views. Two vertical rods are located below the table top, one at each end; running between these is a horizontal unit with two rods supporting the Bucky diaphragm, which can be moved on these rods and travel the table length. This entire horizontal assembly can be raised and lowered on the vertical rods and can be locked in position directly below the table top for conventional work or at varied distances for magnification studies.



Litter-table, *A*, with Bucky diaphragm in conventional position and the head support extended and, *B*, with diaphragm in position for magnification studies and head support dropped.

From the Radiology Service, Veterans Administration Hospital, Bronx (Drs. Stein and Poppel and Miss Hammerschlag), and New York University College of Medicine (Drs. Stein and Poppel).

This table may be used at the bedside with any mobile radiographic machine. Any regular 110-volt wall outlet or adapter plug in a lighting fixture can be utilized. A hand switch from an old x-ray machine used on an extension cord enables us to operate the diaphragm away from the table and near the x-ray control. Poor radiographs resulting from body pressures against mattresses and pillows and inaccurate direction of rays due to uncontrollable angulation are eliminated by use of this solid-surface table. Cassettes are easily placed without disturbing the patient.

Seriously ill patients need not be moved from bed to litter, from litter to x-ray table, from table back to litter, and from litter back to bed. Patients are moved only from bed to new radiotranslucent litter table and back to bed. Those who are very seriously or critically ill can be satisfactorily radiographed without removal from the ward; others are brought to the x-ray department on the litter table. This mobile radiotranslucent litter table has been used in many unanticipated ways. It has been substituted for conventional equipment during temporary breakdown, has simplified the radiography of difficult cases, and often has been used in conjunction with any regular tilt table for special decubitus views of the recumbent abdomen such as are obtained in gallbladder studies with the Kirklin position during cholecystography.

Summary

A mobile litter-table utilizing the Bucky diaphragm has been constructed primarily for bedside use when a minimum of movement of the patient is desired. Conventional and magnification studies can be made, as the diaphragm can be locked in various positions. Cassettes can be easily placed in position. Magnetic cassette holders can be placed along the rim of the table. An extension of the table permits radiographic studies of the skull.

130 W. Kingsbridge Rd., Bronx 68 (Dr. Stein).

Mr. James Douglas, Technical Supervisor, assisted in this project; representatives of the Sommerville Veterans Administration Depot aided in the fabrication and installation of the Bucky diaphragm assembly; and the Picker X-Ray Corporation assisted in the construction of the basic table.

OBSTRUCTED ENDOTRACHEAL TUBE DEMONSTRATED BY ROENTGENOGRAM

Richard C. Thompson, M.D., San Mateo, Calif.

The vexing problem of a partially obstructed endotracheal tube has been encountered twice recently during the course of administration of anesthetics. Roentgenograms were helpful in demonstrating exactly why the tube was obstructed and what happened when the position of the tube was changed to correct the obstruction. In each case the bevel of the endotracheal tube rested against the anterior wall of the trachea. I have found only two references [1] to this problem.

Report of Cases

CASE 1.—A very ill 84-year-old male had a marked kyphosis and a rigid, extended cervical spine. Two large pillows were required to support his head. He was anesthetized and intubated in preparation for a laparotomy. The airway was clear until the metal elbow was disconnected from the curved plastic endotracheal tube to perform endotracheal suction. I assume that the unnatural position of the head caused this curved tube to rotate unnoticed. Soon after the angle piece was reconnected with the tube, the partial obstruction of the airway was recognized; the reason was not apparent. The lungs could be inflated easily, but much of the exhaled gas escaped around the tube, necessitating an increase in flow from the machine. If respirations were not assisted, the patient became cyanosed. Roentgenograms were taken (fig. 1), and the tube was withdrawn and rotated until a clear airway was established (fig. 2).

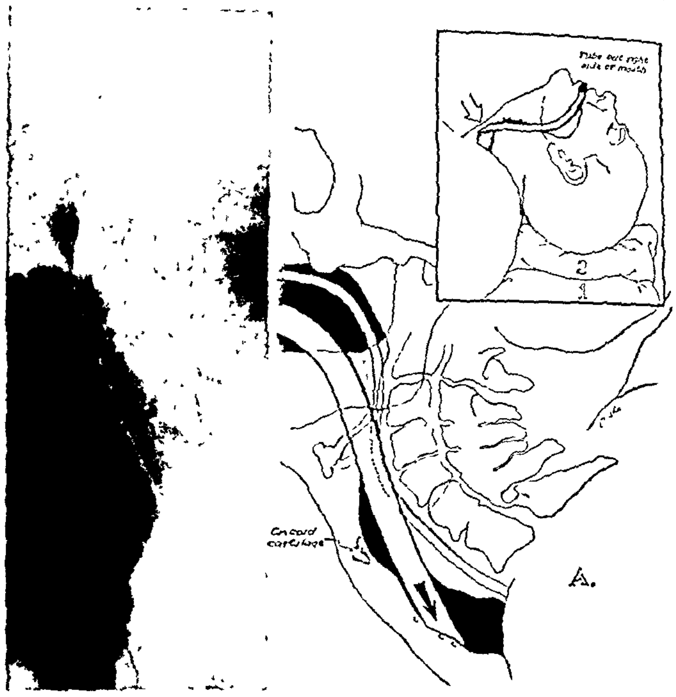


Fig. 1.—During administration of anesthesia in patient in case 1, the bevel of the endotracheal tube has inadvertently rotated anteriorly and has been obstructed by the anterior wall of the trachea.

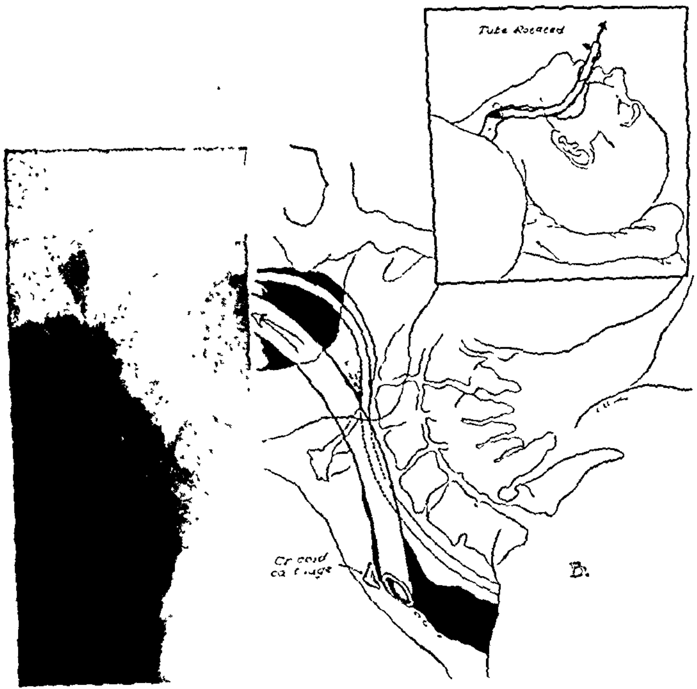

Fig. 2.—The endotracheal tube (case 1) has been withdrawn and rotated to establish a clear airway.

CASE 2.—A husky 42-year-old male was anesthetized for a disk exploration and spinal fusion. The plastic endotracheal airway was perfectly free until he was turned to the prone position. Partial obstruction of the endotracheal tube soon became apparent. The lungs could be readily inflated, but exhalation occurred, chiefly around the tube. Both inhalation and exhalation were noisy, and exhalation was retarded and incomplete Cyanosis became apparent, and a mixture enriched in oxygen was given until after x-rays were taken (fig 3) and the position of the tube changed. In this case, to effect the proper change in position of the tube, the head was rotated to the opposite side and the tube was withdrawn approximately 2 cm (fig 4).

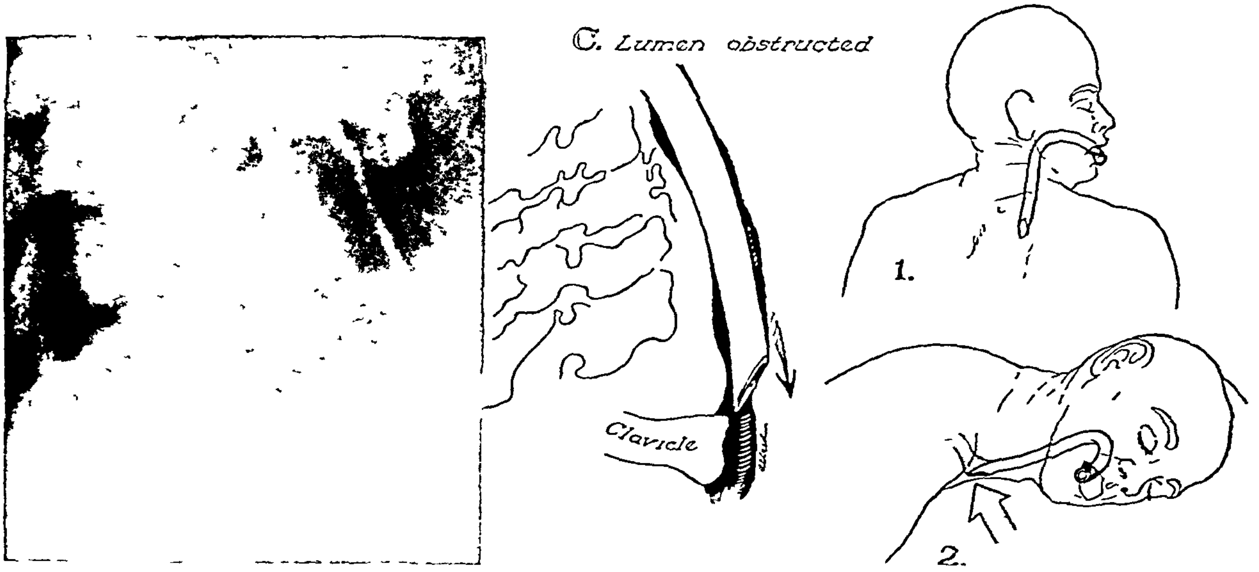

Fig 3 —The patient in case 2 has been placed in the prone position with his head turned to the side The rotation of the head was followed by obstruction of the endotracheal tube as the bevel came to rest against the anterior tracheal wall

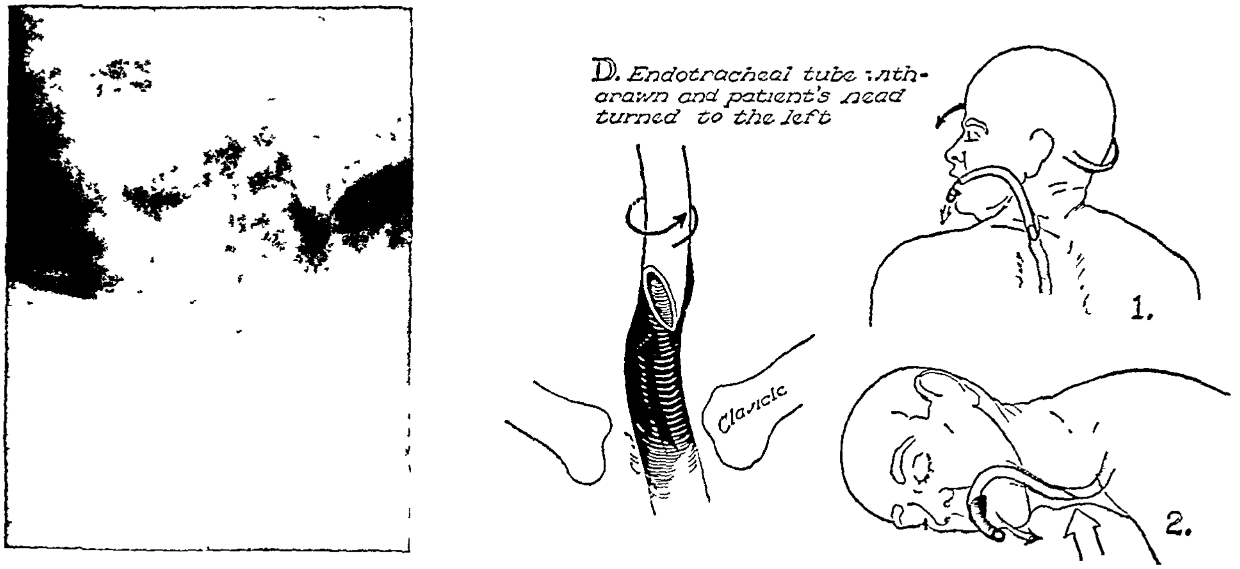

D. Endotracheal tube withdrawn and patient's head turned to the left
Clavicle
1.
2.

Fig 4 —A clear airway has been established (case 2) by turning the head to the opposite side The bevel then faced posteriorly.

Comment

Insert A in figure 1 shows the exaggerated posterior curve in the trachea of the elderly edentulous man with extreme kyphosis; it is not surprising that the tube rotated to the position shown. This is clearly an unusual situation. Case 2 presented a situation that might occur more commonly than is generally recognized. In either the dorsal or prone position, when the head is turned sharply to the side as in certain orthopedic, intracranial, or otological operations, the hazard of obstruction due to apposition of the bevel of the tube to the anterior tracheal wall may occur. Moreover, if the neck is markedly extended, the trachea will curve posteriorly and a slight rotation of the tube may result in obstruction at the bevel. However, the routine use of fenestrated tubes[2] will make endotracheal *anesthesia* a safer procedure.

Summary and Conclusions

In the administration of anesthetics, the bevel of the endotracheal tube may lie against the anterior tracheal mucosa and cause obstruction when the patient's head is turned to the side or unusual circumstances cause rotation of the tube. A fenestrated tube should be selected that will ensure that the bevel faces posteriorly when the head is sharply rotated and extended in an unusual position. The outer end of the endotracheal tube should be marked or notched on the side of the bevel so that the relative position of the bevel will be apparent at all times. When the flow of gases through the tube is impeded, the possibility of apposition of the bevel against the tracheal mucosa should be considered and some suitable manipulation employed to alter such a situation. Roentgenograms were helpful in these cases in demonstrating the cause of endotracheal obstruction.

SIGNIFICANCE OF JAUNDICE FOLLOWING PANCREATODUODENAL RESECTION

George L. Jordan Jr., M.D.
and
Elvin L. Shelton Jr., M.D., Houston, Texas

The value of radical pancreatoduodenal resection for malignant lesions causing obstructive jaundice has been a subject of some debate for many years. Recently there has been a revival of interest in this procedure following encouraging reports that indicate its use may result in a five-year survival rate of 38% for carcinoma of the ampulla of Vater and a five-year survival rate of 15% for carcinoma of the pancreas.[1] Even in the hands of those enthusiastic about the procedure, the recurrence of intra-abdominal symptoms following operation, particularly jaundice, has been taken as evidence of recurrence of disease. Whereas this will be the usual cause, such patients may develop jaundice on any etiological basis. The present case report is that of a patient who developed jaundice due to benign stricture of the common duct one year following pancreatoduodenal resection of a carcinoma of the ampulla of Vater and who is now alive and well five years following his initial surgery and three and one-half years following repair of the stricture.

Report of a Case

A 55-year-old white male was admitted to the Veterans Administration Hospital, Houston, Texas, on Oct. 11, 1950. His history revealed that he had been in good health until six weeks prior to admission, when he noted fever and general weakness. Temperature elevations occurred daily and at times were associated with frank chills. Approximately three weeks prior to admission the patient noted pruritus and jaundice of the scleras; subsequently he noticed that his urine was dark and his stools were light in color. There had been a 12-lb. (5.4 kg.) weight loss. Physical examination was noncontributory, except that the liver was palpated 4 cm. below the costal border and was slightly tender. Laboratory examinations revealed: hemoglobin level, 9 gm. per 100 cc.; serum amylase level, 26 units per 100 cc.; fecal urobilinogen, 21 Erhlich units per 100 gm.; serum bilirubin level, 12.8 mg. per 100 cc.; alkaline phosphatase level, 19.3 Bodansky units per 100 cc.; thymol turbidity, 2 units; and cephalin flocculation test, negative.

The anemia was corrected by blood transfusions. While the patient was being observed in the hospital, the serum bilirubin level decreased to 5.6 mg. per 100 cc. and then increased to 11 mg. per 100 cc. A clinical diagnosis of obstructive jaundice secondary to carcinoma of the duodenum or ampulla of Vater was made, and on Nov. 3, 1950, the abdomen was explored. The gallbladder was distended, as was the common bile duct. The pancreas appeared to be normal, but there was a 3-cm. crater-like lesion at the ampulla of Vater. No metastatic lesions were found. The head, neck, and portion of the body of the pancreas, 30% of the stomach, 2 cm. of common bile duct, and the first, second, and third portions of the duodenum were removed en bloc. The duodenal stump was closed, and a loop of jejunum was brought anterior to the colon for construction of an end-to-side choledochojejunostomy, an end-to-side pancreatojejunostomy, and an end-to-side gastrojejunostomy, with the latter anastomosis being approximately 35 cm. distal to the pancreatojejunostomy. The pathological diagnosis was columnar cell carcinoma of the ampulla of Vater. A biopsy specimen of the liver taken at the time of surgery revealed acute hepatitis with focal abscesses. Postoperatively the patient did well. All laboratory findings returned to normal levels, and within three months the patient gained 20 lb. (10.8 kg.).

In July, 1951, the patient returned to the hospital, complaining of chills, fever, and pruritus, having noted their onset two months before admission. At the time of admission he was asymptomatic and a thorough examination revealed no objective findings. He returned again in January, 1952, with similar complaints. A thorough reevaluation again revealed no abnormality. Scabies was thought to be the cause of the pruritus. However, when he was admitted for the third time on April 22, 1952, physical examination revealed icteric scleras. The serum bilirubin level was 2.7 mg. per 100 cc., and the serum alkaline phosphatase level was 32 Bodansky units per 100 cc. Other laboratory examinations were within normal limits. Surgical exploration was performed on May 9, 1952. Marked scarring at the site of the choledochojejunostomy, with a definite stricture of the common bile duct, was found. The area of stenosis was resected, and a reanastomosis of the common bile duct to the jejunum was performed. He was discharged from the hospital 15 days postoperatively after an uneventful convalescence.

This patient has been seen periodically since the last procedure and has remained in good health. There has been no recurrence of the jaundice or pruritus. He eats without difficulty, he has maintained his weight, and physical examination has remained within normal limits. He was known to be alive and well on Jan. 29, 1956, five years after his initial surgery.

Comment

Most surgeons treating intra-abdominal carcinoma limit their efforts at curative surgery to wide extirpation during the original procedure. Thereafter, if symptoms or signs suggesting recurrent intra-abdominal malignant lesions appear, the situation is considered hopeless. Although this conclusion is justified in most instances, an occasional patient who dies with a clinical diagnosis of recurrent carcinoma will be found to have a benign disease as the cause of death when an autopsy is performed, without evidence of recurrent malignant lesions. Consequently, a thorough evaluation of each patient should be made when new symptoms arise or old symptoms return.

The recurrence of jaundice following pancreaticoduodenal resection for carcinoma of the pancreas or carcinoma of the ampulla of Vater often denotes recurrence of the disease, but the patient we are re-

---

porting presents an example of a benign complication that may produce symptoms and signs suggesting recurrent malignant lesions. The development of a benign stricture is only one of the causes for the occurrence of jaundice after an operation. In the early postoperative period jaundice may be secondary to transfusion reaction, to improper construction of a choledochojejunostomy, or, more rarely, to transient postoperative edema of the stoma. Homologous serum jaundice and infectious hepatitis have produced the same alarming symptoms several weeks or even several months postoperatively. Ascending cholangitis may also occur. This will usually be accompanied by chills and fever. One rarely encounters obstruction of the external biliary tree resulting from a common duct stone. In recent years chlorpromazine (Thorazine)-induced hepatitis has complicated the problem, for the changes in liver function tests that occur are those commonly thought to be typical of an obstructive jaundice.

Furthermore, one occasionally encounters two independent primary carcinomas in the abdomen. One such case was reported by Brunschwig,[2] wherein a radical resection for carcinoma of the ampulla of Vater with lymph node metastases was performed in 1943. Two years later a palpable abdominal mass developed that, upon clinical examination, was thought to be a metastasis from the original lesion. However, a laparotomy was performed, and a second primary carcinoma was found in the ascending colon with nodal metastasis. A right hemicolectomy and node dissection was performed. The patient was alive and well eight years following the original pancreatoduodenectomy and six years following the hemicolectomy.

In many instances, exploratory laparotomy may be the only means of positively establishing a diagnosis, and our experience leads us to advocate reoperation, unless there are proved distant metastases or unless other definite contraindications to operative intervention exist. Cases such as these reported are uncommon, and no one physician is likely to see many. However, such patients will be saved only if a positive diagnosis is established and proper treatment is instituted.

Summary

A patient with obstructive jaundice resulting from carcinoma of the ampulla and treated by pancreatoduodenal resection developed recurrent obstructive jaundice approximately one year following surgery. He was found to have a benign stricture of the common duct, which was successfully treated, and he is alive and well five years following his initial surgery. This case demonstrates the necessity of careful evaluation and treatment of patients with symptoms suggesting recurrent malignant lesions.

METABOLISM AND REQUIREMENTS OF IRON IN THE HUMAN

Carl V. Moore, M.D.
and
Reubenia Dubach, Ph.D., St. Louis

Disturbances of iron metabolism may lead to the development of either iron deficiency or iron excess in the body. The latter state, although comparatively rare, is of increasing clinical importance. It occurs in hemochromatosis, in transfusion hemosiderosis as a result of prolonged excessive iron therapy, and as a part of cytosiderosis, an interesting nutritional abnormality found among the Bantus in Africa. Iron deficiency anemia is one of the most common nutritional deficiencies and one of the most prevalent anemias the world over. In order to understand the pathogenesis and treatment of these disorders, one must know the dietary requirements for iron, how the body uses iron, and how the body normally maintains a positive balance while providing safeguards against excessive accumulations of the metal.

An Outline of Iron Metabolism

Iron, as an essential component of hemoglobin, myohemoglobin, the cytochromes, and other enzyme systems, is required for the important physiological functions of transport of oxygen and cellular respiration. The body of a normal, adult human contains approximately 3 to 5 gm. of iron. Roughly 55% of this total is present in the circulating hemoglobin, about 10 to 20% in myohemoglobin, and a small amount in cells in the form of respiratory enzymes. The remainder is stored chiefly in the liver, spleen, kidney, and bone marrow.

The human absorbs iron mostly, if not entirely, in its ferrous form.[1] Reduction of food iron from the

ferric to the ferrous state begins in the stomach and continues in the intestine. The actual amount of iron absorbed from the stomach is unknown; absorption is probably greatest in the upper portion of the small intestine and progressively smaller in the more distal segments of the gastrointestinal tract. The reason for this diminishing gradient has never been adequately defined. It may be that the ileum, for instance, is not so efficient as the duodenum in absorbing iron, but the difference may be due solely to the fact that insoluble, complex iron salts are formed by the time the iron reaches the ileum.

Patients with iron deficiency or hypochromic anemia absorb inorganic iron more efficiently than do normal persons.[2] The intestinal mucosa serves to some extent as a regulator of iron balance, but the mechanism by which the intestinal mucosa absorbs iron is incompletely understood. The most likely theory is that iron enters the mucosal cells by combining with a protein, apoferritin, to form ferritin, a compound in which colloidal iron hydroxide-iron phosphate micelles are bound to the protein in amounts up to 23% by weight.[3] It is suggested that apoferritin is constantly being formed and broken down; according to this hypothesis, its degradation stops when it combines with iron to form ferritin. The presence of ferritin is thought to cause a block of further absorption of iron until the ferritin can give up its iron to the blood stream, a process that presumably occurs with greater rapidity when iron deficiency exists. This regulatory mechanism seems selective enough to be more efficient when the body requires larger amounts of the metal. That it is only a partial control, however, is indicated by numerous instances in which absorption is relatively great even though the stores of iron are adequate or even large. One must be careful to guard against the erroneous idea that normal persons absorb no iron at all.

Fig. 1.—Schematic outline of iron metabolism.

Iron is absorbed directly into the blood stream rather than through the lymphatic channels (fig. 1). When it passes into the blood plasma, it is oxidized to the ferric state and combined with a specific iron-binding protein, a beta-1 globulin that has been called transferrin, siderophilin, or simply "the iron-binding protein." Each molecule of this specific plasma protein can combine with two atoms of iron; there is enough of it in 100 cc. of plasma to bind from 300 to about 420 mcg. of iron. The amount of iron in plasma, however, normally varies from 50 to 180 mcg. per 100 cc.; only a portion of the beta-1 globulin, therefore, is bound.

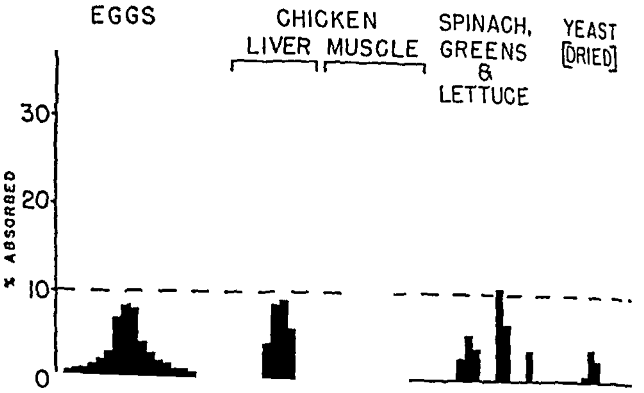

Fig. 2.—Absorption of radioactive iron (Fe^{59}) from food by normal persons. (Reproduced by permission of the *American Journal of Clinical Nutrition.*)

The iron in plasma is transport iron, the hub of iron metabolism. From the plasma, iron can go to organs of storage; it can be utilized, or it can be excreted. A relatively large percentage of the iron goes to the bone marrow where it is used for hemoglobin synthesis, but some is taken up by other cells of the body for the formation of cellular enzymes. The amount of iron in plasma is small, but the turnover rate is rapid, averaging about 0.56 mg. per kilogram of body weight per day.[4] This quantity in a man who weighs 70 kg (154 lb.) would be 39 mg. per day. Since a normal man uses from 20 to 25 mg. of iron per day to make hemoglobin, it is evident that the plasma iron can easily supply the bone marrow's need.

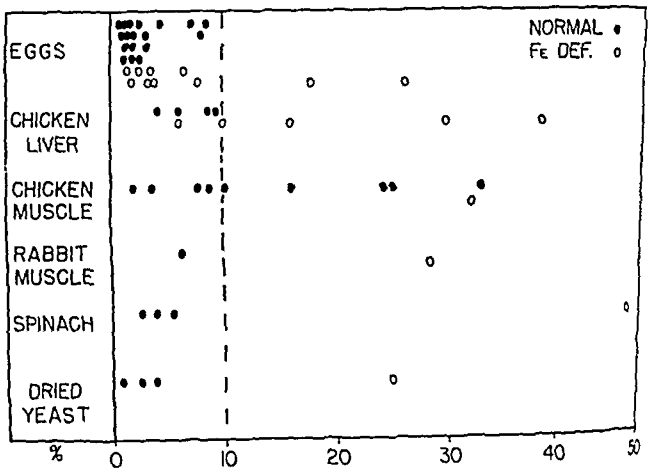

Fig. 3.—Absorption of radioactive iron (Fe^{59}) from foods by normal persons and persons deficient in iron.

One very important characteristic of iron metabolism is the high degree to which the body conserves the metal. When red blood cells are destroyed, almost all the iron released from hemoglobin is reutilized.

Iron released from other cells that die is similarly conserved. Small but significant amounts are excreted from the body. Whenever red blood cells are lost, as in urine or by hemorrhage, or whenever cells are desquamated from the surface of the body or from the gastrointestinal tract, the iron that they contain must be considered to have been excreted.

It has been demonstrated that (1) the amount of iron stored in the tissues of a healthy adult is approximately 1 gm.; (2) the liver and spleen constitute the chief storage sites; (3) storage iron is found intracellularly in a protein complex as ferritin and as hemosiderin.[5] The chemical identity of hemosiderin has not been established, but the suggestion has been made that it may be merely a condensation or clustering of ferritin molecules. In the liver and spleen of normal animals, there is a slight preponderance of ferritin over hemosiderin iron.[5] With larger concentrations of iron in the tissues, this ratio is reversed, and at high levels the additional storage iron is deposited as hemosiderin. Of great physiological importance is the fact that both compounds are capable of being mobilized by the body for hemoglobin synthesis when the need for iron exists.

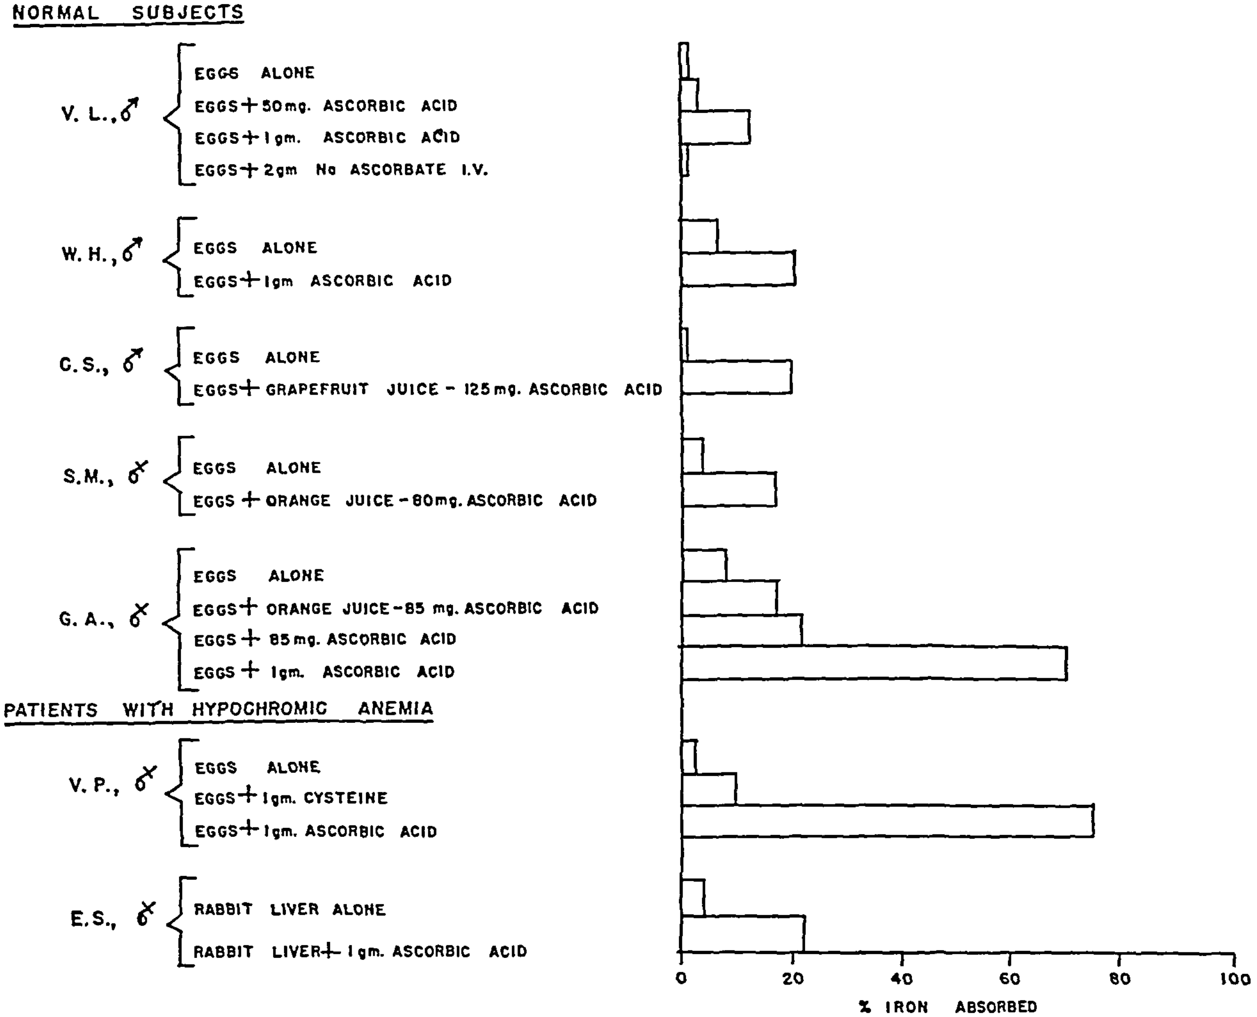

Fig. 4.—Effect of reducing substances on absorption of food iron.

This brief, schematic summary of some of the major characteristics of iron metabolism has emphasized how tenaciously the body conserves iron. It is evident that, if only small amounts of the metal are lost or excreted, the amount absorbed is of prime importance in the prevention of either iron deficiency or overload.

Absorption from Foods

Although a great deal has been learned about the absorption of iron from inorganic salts, we must know how well the metal is absorbed from foods before we can understand the problems of iron nutrition. This information has been very difficult to obtain. Some workers have measured the portion of food iron that can be ionized by dilute hydrochloric acid on the assumption that only ionizable iron can be assimilated. This method is indirect; it ignores the possibility that enzymatic digestion in the intestine may free an additional portion of the food iron, and it cannot indicate what percentage of the ionized iron will be absorbed. Balance studies have been helpful. McMillan and Johnston[6] found that about 12% of the iron in spinach or in a basal diet was absorbed by young college women. Iron is so ubiquitous, however, that the technical difficulties in such balance experiments are enormous.

Recently, more progress has been made with the use of radioactive iron (Fe^{59}). Foods containing Fe^{59} are obtained by growing vegetables in nutrient solutions to which the isotope is added or by injecting iron into hens so that eggs, liver, and muscle contain Fe^{59}.[7] These foods are cooked or prepared as they would be in a normal diet and are fed to fasting subjects. The unabsorbed radioactivity recovered in the feces and the maximum amount that appears in the circulating blood as newly synthesized hemoglobin are both measured. Figure 2 presents the results of a number of such observations, each column representing a separate experiment. With only two exceptions—the most striking exception being from chicken muscle—less than 10% of the food iron was absorbed by *normal persons. Similar observations* of patients deficient in iron revealed that very few of them absorbed iron from eggs any more efficiently than did normal persons. In a few observations made with chicken liver, spinach, and dried (brewer's) yeast, it appears that patients with iron deficiency anemia tend to absorb these forms of food iron somewhat more efficiently (fig. 3). When other foods were fed at the same time as eggs, only citrus fruit juices, containing a relatively high concentration of ascorbic acid, augmented the assimilation of the Fe^{59} (fig. 4). The increased absorption produced by 200 cc. of orange juice and the increase produced by an equivalent amount of crystalline *ascorbic acid* were similar (see G. A., fig. 4). The addition of 0.25 to 1 gm. of crystalline ascorbic acid to a number of different foods increased iron absorption in every case, with perhaps a slightly greater effect in the subjects deficient in iron. It is suggested that ascorbic acid produces this result by more *efficiently reducing* ferric iron in food to the *ferrous state.*

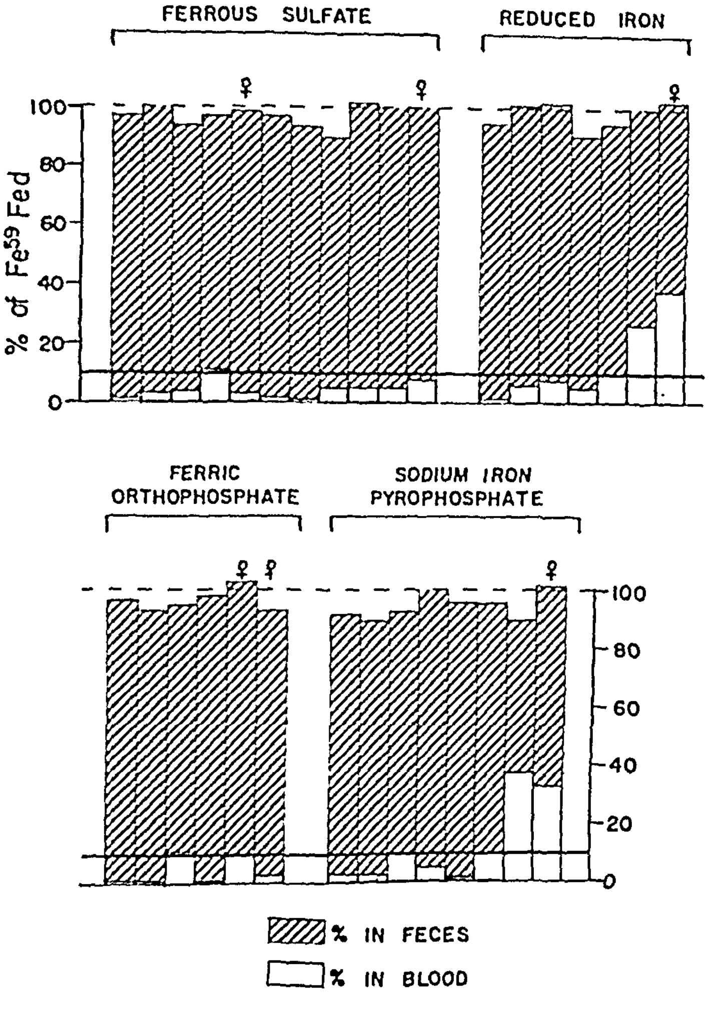

Fig. 5.—Absorption of four radioactive iron (Fe^{59}) preparations from enriched bread. Two of the four persons who absorbed more than 10% of the iron were young women whose loss of menstrual blood was above normal; the remaining two were two young men who had served repeatedly as blood donors. (Reproduced by permission of the A. M. A. *Archives of Internal Medicine.*)

A preliminary attempt has been made to evaluate the importance of gastric hydrochloric acid in the absorption of iron from food. For many years it has been taught that patients with hypochlorhydria or achlorhydria probably assimilate iron poorly. In such patients, however, we were not able to increase the absorption of iron by adding 60 cc. of 0.1 *N* hydrochloric acid to the food or by adding enough *N* hydrochloric acid to reduce the pH of the mixture to 1.5 before it was given by stomach tube. On the other hand, administration of 0.25 to 1 gm. of ascorbic acid increased absorption very significantly, even though this amount had comparatively little effect on gastric acidity.

These results can be summarized in the following manner. 1. Fe^{59} has been incorporated into eggs, chicken muscle, chicken liver, mustard greens, spinach, and dried yeast. 2. With three exceptions, the absorption of Fe^{59} from foods by 40 normal persons has been less than 20%; *with only six exceptions* it has been less than 10%. 3. Ascorbic acid and foods containing ascorbic acid have enhanced the absorption of food iron. 4. Persons deficient in iron absorb iron from foods somewhat better than do normal persons particularly if the food iron is reduced by ascorbic acid. 5. In preliminary observations, the addition of acid in patients with hypochlorhydria has not influenced absorption of food iron.

The diet of healthy adults in the United States contains approximately 12 to 15 mg. of iron per day. If the aforementioned figures are used as a basis for calculation, the amount of iron absorbed from food per day probably varies from about 0.6 to 1.5 mg. Poor diet, infection, steatorrhea, or diarrhea would decrease this amount even further. The effect of steatorrhea in reducing the absorption of iron by patients with hypochromic anemia has been demonstrated recently.[8]

Of related interest are observations recently completed on the absorption of iron from bread baked with flour that had been enriched with Fe^{59}.[9] In the food fortification program in the United States, iron is added as powdered metallic iron, as sodium ferric pyrophosphate, as ferric orthophosphate, or as ferrous sulfate in amounts sufficient to provide 6 to 8 mg. of iron per pound loaf of bread; however, the effectiveness of this particular type of fortification has not been evaluated adequately, and several of the preparations are so insoluble that one wonders how valuable they are. Each of the four iron preparations was obtained in radioactive form and baked into bread by a pilot bakery, along with other substances used in fortification. The baking process simulated as closely as possible that used by large commercial bakeries. Four slices of the bread were then fed to 32 healthy medical students and 3 persons with iron deficiency anemia, and absorption was measured. Twenty-eight of the 32 students absorbed and utilized between 1 and 12% of the iron, regardless of the form of iron added. The other four students assimilated 26 to 38% of the Fe^{59}, but there was reason to suspect that their iron stores were suboptimal (fig. 5). Apparently the various iron preparations are changed in the baking process, probably to a complex salt, so that all are about equally effective. The three patients with iron deficiency anemia assimilated 45 to 64% of the iron taken. Addition of 1 gm. of ascorbic acid to the bread eaten by six of the healthy persons increased the absorption of iron two to three times.

Excretion of Iron

Because iron is conserved so tenaciously and because the amount excreted is small, many people have mistakenly assumed that no iron whatever is lost from the body except as shed blood. The error of this assumption becomes obvious from the following considerations. All cells in the body contain iron. When leukocytes and epithelial cells are discharged in body secretions, when erythrocytes appear in urine, when cells are desquamated from the skin or the mucosa of the intestinal tract, and even when hair grows, some iron is lost. Attempts to estimate this amount, and to determine in addition how much is excreted in other ways have proved to be very difficult. The metal is so ubiquitous that it has been almost impossible to differentiate between excreted iron and that present because of contamination or failure to be absorbed. Fe^{59} has provided a partial solution to the problem.

The isotope has been injected in tracer amounts into the veins of normal subjects and patients with hypochromic or hemolytic anemias.[10] Five-day fecal collections were made at intervals for up to 150 days; this long period was used because most of the injected Fe^{59} was promptly synthesized into hemoglobin, and it was essential to continue the observations longer than the 120-day lifespan of erythrocytes. Every fecal specimen of every person contained a detectable amount of radioactivity; the amount averaged 0.01% of the dose per day for normal persons. Three patients who were deficient in iron excreted much less, whereas one young woman with a hemolytic (sickle cell) anemia excreted more. No significant increase in fecal radioactivity was detected at or near the 120th day after the injection. However, it is difficult to calculate from these figures the fecal excretion of all body iron—inert as well as radioactive. Two calculations were made: one from the ratio of total hemoglobin iron to radioactive hemoglobin iron, the other from the ratio of estimated total body iron to the injected dose of the isotope (fig. 6). Fecal excretion calculated in these ways for normal persons varied from 0.3 to 0.5 mg. per day. For patients deficient in iron, the value was about one-tenth as much. Although these calculated values are estimations, it is reasonably certain that they do not vary from true figures by more than 100%. With this method of determination, one cannot differentiate between the following three possible sources of fecal iron: (1) true excretion, (2) desquamated mucosal cells, and (3) iron delivered to the duodenum via the bile and not completely absorbed.

Some of the injected Fe^{59} was also found regularly in sweat for at least 320 days, the longest time after administration that a collection was made. The amount was small but definitely measurable. We were not able to determine whether it came from sweat glands by a process of true excretion or from desquamated epithelial cells. Calculations indicated that under normal conditions the total iron lost from dermal surfaces is certainly less than 1 mg. per day and probably not more than 0.5 mg. Radioactivity could also be detected in hair clippings obtained several months after the injection of radioiron and washed with dilute hydrochloric acid to free them from surface (sweat) contamination. The small amount of iron found in urine must also be considered.

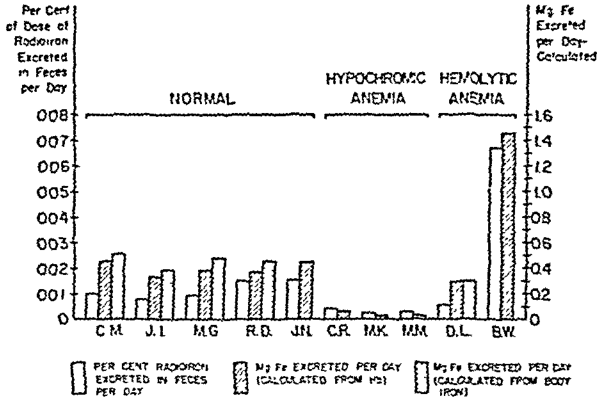

Fig. 6.—Average daily radioiron excretion and calculated total iron excretion of 10 human subjects. (Reproduced by permission of the *Journal of Laboratory and Clinical Medicine.*)

One can estimate that the adult male loses or excretes a total of 0.5 to 1.5 mg. of iron per day; the median value of 1 mg. is probably not in error by more than 20 to 25%. Menstrual blood flow of 35 to 70 cc. every 28 days in a normal woman with a hemoglobin value of 12 gm. would account for an additional average loss of 0.5 to 1 mg. per day. The donation of blood for transfusion purposes has become so common that this type of blood loss must also be considered in any discussion of excretion of iron. When 500 cc. of blood with a hemoglobin value of 15 gm. per 100 cc. is withdrawn, the donor loses approximately 0.25 gm. of iron. This amount spread evenly over a year averages about 0.68 mg. per day. It is evident that multiple donations, not covered by supplemental iron, would constitute a severe drain on the body's iron economy.

Observations on humans emphasize the fact that nutritionally significant amounts of iron are lost or excreted, but these studies are admittedly semiquantitative. The only truly quantitative experiments have been done by Finch and his associates on mice.[11] They have obtained surprising results by using a counter that permitted them to make measurements of radioactivity on the whole animal. Mice were killed at intervals for 300 days after injection of Fe^{59}; only half of the radioactivity could be recovered from the whole carcass after about 140 days.[11a] Furthermore, under experimental conditions of induced iron overload, the amount of iron excreted was increased proportionally to the increase in body iron.[11b] These data suggest that, in the mouse, excretion, as well as absorption, plays an important role in maintaining normal iron balance. All available evidence indicates that the human excretes iron more sparingly, even though in nutritionally significant amounts.

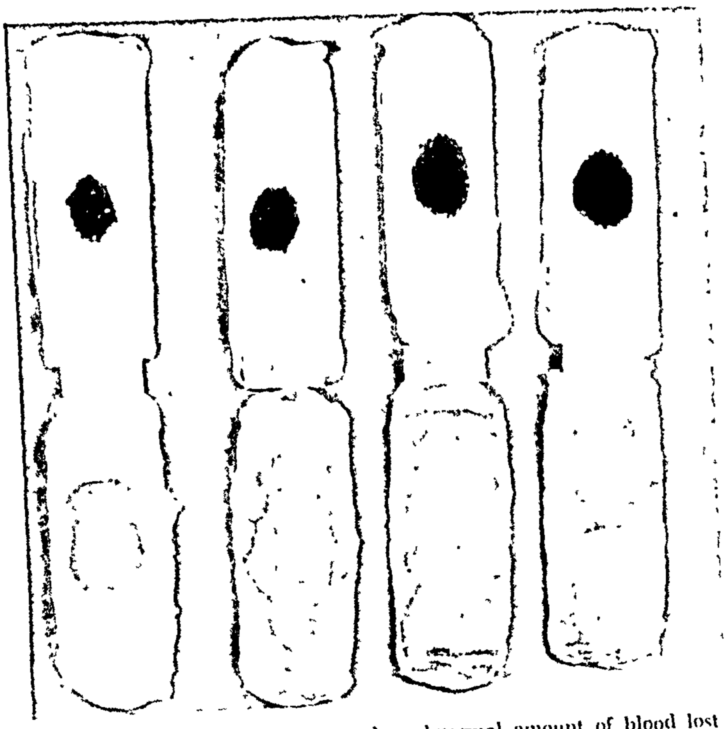

Fig. 7.—Pads prepared to show that abnormal amount of blood lost in menstrual flow may be accepted as normal. Blood in the amounts of 5, 10, 15, and 20 cc. was placed on pads. The four pads at the top were not disturbed; those at the bottom were rubbed together at edges to simulate agitation occurring with walking.

Importance of Nutrition in the Pathogenesis of Iron Deficiency Anemias

Although the data presented for the absorption of iron from food and for the excretion of iron are incomplete and provide approximations only, they permit a better evaluation of the importance of nutritional factors in the pathogenesis of iron deficiency than has been possible previously. If the adult male absorbs an average of 10% of the iron in a diet that contains 12 to 15 mg. per day, he retains 1.2 to 1.5 mg. Since he excretes only about 1 mg. or less of iron per day, he maintains a positive balance rather easily. The adult female, however, during the years of menstruation and child bearing, tends to eat less and loses additional amounts. During gestation a mother furnishes her fetus with about 0.3 to 0.5 gm. of iron, or between 1 and 2 mg. per day. The normal volume of menstrual blood is approximately 35 to 70 cc. If the hemoglobin value of that blood is 12 gm. per 100 cc., then 14 to 28 mg. of iron is involved. Spread evenly over a 28-day menstrual cycle, this amount equals 0.5 to 1 mg. per day. Iron balance in a young woman, therefore, is precarious; poor diet or poor absorption may lead to iron deficiency even though menstrual loss remains normal. Frequent pregnancies or any increases in menstrual flow make her more susceptible. Furthermore, women are often unaware of the fact that they might be losing several times the normal amount of menstrual blood. Menstrual pads absorb blood so efficiently that false impressions are obtained. The pads in figure 7 were prepared by adding onto their surfaces 5, 10, 15, and 20 cc. of blood, respectively. The four at the top were not disturbed. Those at the bottom were rubbed together at the edges to simulate the agitation that might occur with walking. In no instance did the blood soak through more than three-fourths of the material. Women physicians who inspected and watched the preparation all agreed that at least the pads to which 10 cc. had been adde would be considered "normal." It is evident that woman who uses 10 to 15 pads per period might easi lose more than 100 cc. of blood without being awa of any abnormality. The authors have seen two inte gent, medically trained women with hypochro anemia whose extracted pads contained in excess of 200 cc. of blood per period; neither one had been aware that her blood loss was unusual.

‡ Hemoglobin, 7.5 gm./100 cc.
§ Assuming that no iron is absorbed and 1 mg. is excreted daily.

Almost nothing is known about excretion of iron in children, but the infant and the growing child need iron to increase their blood volume, their myohemoglobin volume, and the respiratory enzymes required by all cells. Since the body of an infant contains about

0.5 gm. of iron and that of an adult 3 to 5 gm., there must be a net gain during the first 20 years of life of 2.5 to 4.5 gm.; this net gain averages 0.12 to 0.22 gm. per year or about 0.35 to 0.6 mg. per day. In all probability, the positive iron balance maintained by normal children during their most active growth must be slight, and poor diet or poor absorption could readily produce iron deficiency.

It is much more difficult for iron deficiency to develop in the adult male or the postmenopausal female on a purely nutritional basis without any associated blood loss. The calculations in table 1, based on two hypothetical patients, an adult male and a postmenopausal woman, demonstrate that, if these two persons each excreted 1 mg. of iron per day and absorbed none at all, periods of six and four years, respectively, would pass before they became deficient enough to have only 7.5 gm. of hemoglobin per 100 cc. These figures ignore the evidence that as patients become deficient in iron they excrete smaller amounts of the metal. Any iron contained in the deficient diet, furthermore, would tend to be assimilated with greater than normal efficiency unless there were a serious absorptive defect in the intestinal tract. Both factors would considerably delay the appearance of iron deficiency anemia. One must admit, however, the theoretical possibility that men or postmenopausal women who consume very deficient diets or who have absorptive defects could, over a period of many years, develop iron deficiency on a nutritional basis alone. On the other hand, it seems far more likely that patients with inadequate diets or poor absorption also lose small amounts of blood that go undetected. The bleeding may be slight and intermittent, so that diligent search is required for its detection. There is some evidence that blood added in small amounts to the stomach may be so completely digested that tests for occult blood in the feces remain negative.[12] With hemorrhage, even though slight, inadequate iron intake or absorption becomes of major importance in the pathogenesis of hypochromic anemia.

[*] Recommended Dietary Allowances, A Report of the Food and Nutrition Board, Publication 302, National Research Council, 1953.

It is evident from the considerations reviewed in this section, from the incomplete state of our knowledge about the absorption of iron from foods, and from the meagerness of our information about excretion of iron in the human that a precise definition of dietary iron requirements is not yet possible. The recommendations of the Food and Nutrition Board seem to be adequate, and they probably represent as good approximations as can be made at present (table 2). These quantities of food iron, however, do not provide a wide margin of safety except, perhaps, for the adult man and the postmenopausal woman.

Iron Overload

Iron overload is of increasing clinical importance.[13] It is discussed briefly herein because increased absorption of iron, sometimes associated with high oral intake of the metal, is of pathogenic importance in some forms of overload. Iron overload occurs in hemochromatosis and in transfusion hemosiderosis; it occurs as a result of prolonged excessive iron therapy and as a part of an interesting nutritional abnormality in Africa called cytosiderosis. The natives who develop cytosiderosis eat primarily a diet of maize cooked for long periods of time in iron pots. This cooking process, plus the Kaffir beer drunk by the natives, makes the iron content of the diet abnormally high, often more than 100 mg. per day. A few years ago Hegsted, Finch, and Kinney showed that rats fed maize also absorbed abnormally large quantities of iron. They made the interesting observation that the maize diet is low in phosphorus, and they postulated that there was, consequently, less of a tendency for the iron to be precipitated as insoluble phosphate salts in the intestinal tract.[14] The addition of phosphate to the experimental diet corrected the tendency for increased absorption.

The large amounts of iron in transfusion hemosiderosis are easy to understand, since every pint of blood contains from 0.2 to 0.25 gm. of iron. One hundred transfusions would provide the recipient with 20 to 25 gm. of the metal. Some workers have found at autopsy more than the expected amount of iron in the tissues of patients who had had frequent transfusions and have postulated that some of them must absorb iron at rates greater than normal, even though the tissues are overloaded. Definitive experiments to prove this have not been done.

In true idiopathic hemochromatosis, the increased amounts of iron have been something of a mystery. The iron must reach the body by absorption; but, while it is possible to demonstrate that some patients with hemochromatosis do absorb the metal at a rate greater than normal, others seem to have a normal rate of assimilation.[15] It has been suggested that the absorption is greater than normal until the late stages of the disease, when the tissues are so laden with iron that assimilation becomes retarded.[13] The mechanism of the increased absorption is unknown.

In hemochromatosis, the iron overload is frequently associated with fibrosis of the liver, diabetes, and evidence of myocardial damage. The question naturally arises as to how much of these associated changes is caused by a cytotoxic effect of the high iron concentrations. In the Bantu with cytosiderosis, diabetes is rare but hepatic cirrhosis is usually found. The cirrhosis in these cases may possibly be explained by other nutritional deficiencies. In transfusion hemosiderosis, diabetes develops in only a minority of patients, and cirrhosis, when it occurs, may possibly be the result of serum hepatitis, other infection, or prolonged hypoxia of the liver.

In our laboratory, dogs that received 0.5 to 1 gm. of iron per kilogram of body weight—amounts comparable to those found in hemochromatosis—are still well after six years.[16] They have no laboratory evidences of hepatic disease or of diabetes. Between 1945 and January, 1951, one of our patients with refractory or hypoplastic anemia received 587 transfusions containing well over 100 gm. of iron. He recovered, after splenectomy, and has received no transfusions during the past four years. He is well and has no diabetes nor any evidence of liver disease, although his skin is still bronzed.

There is reason to wonder if iron alone causes the cirrhosis and diabetes of hemochromatosis. Iron overload must be present, plus some unknown factor, to produce these changes. The unknown factor may be an associated metabolic disturbance or some intercurrent event responsible for liver damage, or it may be only time. Patients with hemochromatosis have iron overload over a period of many years. Patients with transfusion hemosiderosis usually receive transfusions because of diseases incompatible with long life. That iron is cytotoxic in high concentration is not denied. We wish merely to emphasize that other factors may play a pathogenic role in the production of abnormalities found in association with iron overload.

Summary

Nutritional factors are of major importance in the production or prevention of iron deficiency. Under some circumstances, when the intake is greatly increased, they can be responsible for iron overload. Healthy persons probably maintain a positive iron balance by a narrower margin than was formerly believed. Approximately 5 to 10% of the iron in food seems to be assimilated by normal adults; daily retention on a diet containing 12 to 15 mg. of iron, therefore, can be estimated to be about 0.6 to 1.5 mg. The amount of iron lost from the body each day in all ways except as blood seems to be between 0.5 and 1 mg. The requirements needed additionally by children and young women for growth and to compensate for menstrual flow place them in a precarious state of iron balance; poor diet or poor absorption can readily lead to the production of hypochromic anemia. In adult men or postmenopausal women, nutritional factors appear to be of less importance in the pathogenesis of iron deficiency. If purely nutritional iron deficiency ever occurs in these persons, many years would be required for its production. It is more likely that occult, intermittent bleeding, often difficult to detect, must also be present, along with inadequate diet or malabsorption, before severe degrees of iron deficiency develop.

One may conclude that for the normal child or the normal adult the recommendations of the Food and Nutrition Board for iron are adequate; however, they do not provide a wide margin of safety.

This study was supported in part by a grant from the National Hea Institute of the United States Public Health Service.

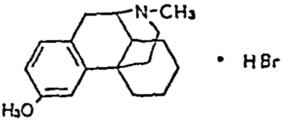
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

H. D. Kautz, M.D., *Secretary.*

Dextromethorphan Hydrobromide.—*d*-3-Methoxy-N-methylmorphinan hydrobromide.—The structural formula of dextromethorphan hydrobromide may be represented as follows:



Actions and Uses.—Dextromethorphan hydrobromide, a synthetic morphine derivative, is employed exclusively as an antitussive agent. Unlike codeine, dihydrocodeinone, and many of the other opium alkaloids used for this purpose, it exhibits little or no central depressant activity and does not produce analgesia. In addition, the drug appears to have no addicting effects, even after prolonged use in rather high doses. Its toxicity is low; side-effects reported to date have been slight, and there is some doubt that these can be attributed to the drug at all. The amount of bromine present in therapeutic doses is of no clinical significance.

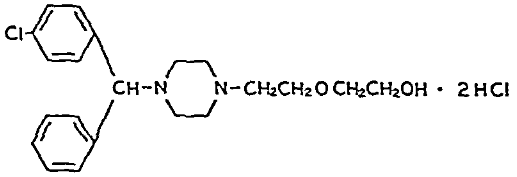
As with any antitussive drug, it is extremely difficult to obtain unbiased clinical data on effectiveness. With agents that have concomitant sedative actions, the possibility exists that patients become less conscious of and, hence, less bothered by cough although the actual frequency and intensity of cough is little affected. Dextromethorphan, however, has been subjected to well-controlled clinical evaluation. In a series of patients with severe chronic cough of varied etiology, dextromethorphan hydrobromide, codeine, and a placebo were administered under double-blind conditions; cough was rated numerically and recorded four times daily. The data obtained from a large number of such observations were subjected to a statistical analysis of variance. Only after the data had been thus analyzed was the identity of the medicaments revealed. These studies demonstrated that both dextromethorphan and codeine produced a definite and significantly greater diminution in cough than did the placebo. Thus, dextromethorphan hydrobromide compares favorably with the other antitussives used in clinical practice. Its activity in this respect is approximately as great as that produced by equal amounts of codeine.

Dosage.—Dextromethorphan hydrobromide is administered orally. The average dose for adults is 10 to 20 mg. one to four times daily. This dose is reduced to one-half for children over 4 years of age and to one-quarter for children under 4 years of age.

Preparations for use as stated for the foregoing drug are marketed under the following name: Romilar Hydrobromide.

Hoffmann-La Roche, Inc., cooperated by furnishing scientific data to aid in the evaluation of dextromethorphan hydrobromide.

Hydroxyzine Hydrochloride.—1-(*p*-Chlorobenzhydryl)-4-[2-(2-hydroxyethoxy)ethyl]piperazine dihydrochloride.—The structural formula of hydroxyzine hydrochloride may be represented as follows:



Actions and Uses.—Hydroxyzine hydrochloride, which is similar in chemical structure and pharmacological action to some of the antihistamines, produces depression of the central nervous system. Sedation is the most prominent action of hydroxyzine hydrochloride and forms the basis for its clinical use. The drug also appears to exert some actions similar to those of chlorpromazine; however, these are not sharply enough defined to permit pharmacological classification as a chlorpromazine-like drug.

Hydroxyzine hydrochloride has been employed clinically as a tranquilizing or calming agent for the symptomatic treatment of a wide variety of emotional or mental disorders characterized by anxiety, tension, and agitation; however, sufficient experience has not been gained to determine its ultimate usefulness as a psychotherapeutic agent. To date, its use in patients with frank psychoses has not been promising. The drug is likewise of little benefit in depressive states unless there is a strong overlay of agitation and anxiety. On the basis of currently available evidence, it would appear to be useful for the symptomatic management of neuroses rather than psychoses.

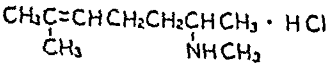
The toxicity of hydroxyzine hydrochloride is low. Drowsiness may occur shortly after the drug is taken but is transient and apparently never proceeds into true sleep. This effect, as distinguished from the tranquilizing action of the drug, seems to diminish in frequency and intensity upon prolonged administration.

Dosage.—Hydroxyzine hydrochloride is administered orally. The usual dose for adults is 25 mg. three times daily, but this may vary in amount and frequency according to severity of symptoms and individual response. For children between 6 and 12 years of age, doses of 10 mg. twice a day have been employed. This may be increased to 10 mg. three to four times daily if necessary. Sufficient experience is not available to state dosage requirements for infants or children under the age of 6.

Preparations for use as stated for the foregoing drug are marketed under the following name: Atarax Hydrochloride.

J. B. Roerig and Company, Division of Chas. Pfizer & Company, Inc., cooperated by furnishing scientific data to aid in the evaluation of hydroxyzine hydrochloride.

Isometheptene Hydrochloride.—2-Methylamino-6-methyl-5-heptene hydrochloride.—The structural formula of isometheptene hydrochloride may be represented as follows:



$$\underset{\displaystyle CH_3}{CH_3C}{=}CHCH_2CH_2\underset{\displaystyle NHCH_3}{CH}CH_3 \cdot HCl$$

Actions and Uses.—Isometheptene hydrochloride, an unsaturated aliphatic amine, exhibits antispasmodic and vasoconstrictor properties. Thus, in experimental animals it produces relaxation of smooth muscle of hollow organs, including the urinary and gastrointestinal tract and the sphincters of the bile duct, pancreatic duct, and urinary bladder. Its antispasmodic effect on these structures is caused by stimulation of sympathetic (inhibitory) nerve endings rather than by inhibition of parasympathetic endings, as with atropine. The drug resembles epinephrine in that it produces moderate peripheral vasoconstriction, an increase in the contractile force of the myocardium, and a transient increase in blood pressure. Other effects include a slight bronchodilation, mydriasis, respiratory stimulation, and a shrinkage of nasal and pharyngeal mucosa. Isometheptene hydrochloride therefore may be classified as a sympathomimetic amine.

On the basis of these pharmacological studies, isometheptene hydrochloride has been employed clinically for the treatment of urinary tract spasm and spastic conditions of the gastrointestinal tract and its sphincters, as well as for the relief of migraine-like headache and other conditions believed to be caused by vasodilation in the cranial and cerebral vascular beds. Although it is the clinical impression of some physicians that patients with such conditions are benefited, convincing evidence is lacking to indicate that the drug, rather than the natural course of the disease, is responsible for alleviation of symptoms. Thus, the usefulness of isometheptene hydrochloride for relieving the pain of ureteral colic, as an aid in the passage of stone, for facilitating instrumentation during urologic or gastrointestinal examination, for relaxing gastrointestinal spasm, or for the alleviation of migraine or tension headache or histaminic cephalalgia is unsettled. Since pharmacological studies indicate that it may have some use in such conditions, and since it is of low clinical toxicity, its therapeutic trial may be justified in appropriate cases.

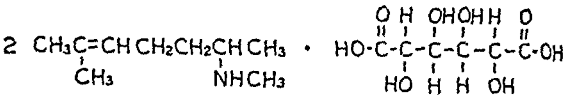
After parenteral administration of isometheptene hydrochloride, the most common side-effect is a rise in blood pressure, particularly in patients with a labile vascular system. This occurs much less frequently after oral administration. Other minor side-effects, which are rare and transient, include lightheadedness, nervousness, and sometimes nausea. The drug is contraindicated in all hypertensive patients. Initial parenteral administration should follow injection of a small test dose with subsequent careful checks on blood pressure.

Dosage.—Isometheptene hydrochloride is administered orally or intramuscularly. The usual oral dose for adults is 15 to 20 drops of a 10% solution (containing 100 mg. per cubic centimeter) every half hour for a total of four doses. By the intramuscular route, 50 to 100 mg. is injected for the control of acute pain in adults, but oral therapy should be substituted as soon as possible. The drug should never be injected intravenously.

Preparations for use as stated for the foregoing drug are marketed under the following name: *Octin Hydrochloride.*

Bilhuber-Knoll Corp. cooperated by furnishing scientific data to aid in the evaluation of isometheptene hydrochloride.

Isometheptene Mucate.—2-Methylamino-6-methyl-5-heptene mucate.—The structural formula of isometheptene mucate may be represented as follows:



$$2\ \underset{\displaystyle CH_3}{CH_3C}{=}CHCH_2CH_2\underset{\displaystyle NHCH_3}{CH}CH_3 \cdot HO{-}\underset{}{\overset{O}{\overset{\|}{C}}}{-}\underset{\displaystyle HO}{\overset{\displaystyle H}{C}}{-}\underset{\displaystyle H}{\overset{\displaystyle OH}{C}}{-}\underset{\displaystyle H}{\overset{\displaystyle OH}{C}}{-}\underset{\displaystyle OH}{\overset{\displaystyle H}{C}}{-}\overset{O}{\overset{\|}{C}}{-}OH$$

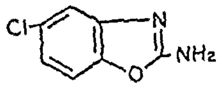
Actions and Uses.—Isometheptene mucate has the same actions and uses as the hydrochloride salt. (See the monograph on isometheptene hydrochloride.) Because it is not used by the parenteral route, it rarely causes hypertension.

Dosage.—Isometheptene mucate is administered orally or rectally. The usual oral dose for adults i 0.12 gm. every half hour for a total of four doses. Alternatively, one suppository containing 0.25 gm. may be inserted into the rectum; this procedure may b repeated in one hour if necessary.

Preparations for use as stated for the foregoing drug are marketed und the following name: Octin Mucate.

Bilhuber-Knoll Corp. cooperated by furnishing scientific data to aid the evaluation of isometheptene hydrochloride.

Zoxazolamine.—2-Amino-5-chlorobenzoxazole.—Th structural formula of zoxazolamine may be represented as follows:



Actions and Uses.—Zoxazolamine, a skeletal muscle relaxant, depresses or interrupts transmission of nerve impulses through polysynaptic pathways. Like mephenesin, its major sites of action are the brain stem, subcortical areas, and the spinal cord. Experiments with animals indicate that the drug has no direct effect on skeletal muscle, nor does it act at the myoneural junction. With experimental methods currently employed, comparatively little effect can be detected on monosynaptic arcs. Zoxazolamine has a longer duration of action than mephenesin and, in comparable dosage, its spasticity-reducing potency is greater. It likewise is more effective by mouth than mephenesin in equal amounts.

Zoxazolamine has been employed in a wide variety of conditions that may be unrelated in pathogenesis but in which either skeletal muscle spasm or spasticity is present as a common denominator. Of these disease entities, those resulting from musculoskeletal disorders, such as sprains, muscle strains and contusions, low back disorders, fibrositis, bursitis, myositis, and spondylitis, appear to respond best to the drug. A high percentage of patients with these conditions may be expected to be benefited by the drug with attending relief of muscle spasm discomfort. In such conditions, the drug should not be expected to bring about permanent improvement without appropriate attention to the application of suitable physical therapeutic measures. In patients with rheumatoid arthritis and osteoarthritis, the drug is of limited usefulness as an adjunct to salicylate and other forms of therapy. Although the drug may aid in the relief of muscle spasm, the concomitant production of muscular weakness in some cases can result in decreased over-all functional activity. The agent is of questionable usefulness in cervical root syndrome.

In general, patients with muscle spasm and spasticity resulting from musculoskeletal disorders appear to respond better to zoxazolamine than those with neurological disease. Of the latter category, beneficial results have been attained chiefly in patients with cerebral involvement, as for example, cerebral palsy and spastic paraplegia. Excluding those cerebral spastic states with athetoid derangements, the drug has been moderately successful in relieving hypertonus of the involved muscle groups in some patients. The more severe type of neurological spasticity states, namely those involving the spinal cord, have so far responded less well to zoxazolamine. These include such conditions as cord injury or neoplastic involvement and multiple sclerosis; results are likewise often disappointing in Parkinson's disease and various pyramidal tract lesions. The drug has no effect on basal ganglion disorders or convulsive diseases such as epilepsy.

Zoxazolamine has a margin of safety greater than that of mephenesin. Excessive muscle fatigue, which can occur after administration of both agents, is less pronounced after zoxazolamine. Side-effects to its administration, though frequent and often unpleasant, are not serious and are reversible upon withdrawal of the drug. The most frequent of these are nausea and vomiting; other less frequent side-effects include anorexia, headache, lightheadedness, transient skin rash, malaise, weakness, and drowsiness.

Dosage.–Zoxazolamine is administered orally. The usual dosage for adults is 0.25 to 0.5 gm. three or four times daily during meals or with food. For children, a dose of 0.25 gm. two to four times a day may be administered.

Preparations for use as stated for the foregoing drug are marketed under the following name: *Flexin.*

McNeil Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of zoxazolamine.

Additional Uses of Acetazolamide

The Council has evaluated the use of acetazolamide for the treatment of toxemia and edema of pregnancy, premenstrual tension, obesity, and drug-induced edema. This diuretic agent previously has been found useful for the management of cardiac edema, epilepsy, and glaucoma. On the basis of currently available evidence, the Council concluded that its oral administration to patients with toxemia and edema of pregnancy often will provide relief from the fluid retention that accompanies or characterizes mild preeclampsia of the third trimester. The drug is also useful for the treatment of the discomforts of premenstrual tension associated with fluid and electrolyte retention. Acetazolamide has been employed as an adjunct to dietary and other therapeutic measures for the management of simple obesity and excessive weight gain during pregnancy; preliminary results indicate a salutary effect in some patients. The drug also may be administered with phenylbutazone or cortisone to control the edema induced by these agents. The possibility of untoward effects from long-term use has not been assessed.

Acetazolamide is administered orally for all of the foregoing indications. Doses of 0.25 gm. daily are usual for the treatment of toxemia and edema of pregnancy. For premenstrual tension accompanied by fluid retention, doses of 0.25 gm. per day beginning 6 to 10 days prior to onset of menstruation or at the onset of symptoms have been employed; however, doses considerably lower than this may be adequate. The average dose for the adjunctive management of obesity is 0.25 gm. each day. When control of drug-induced edema is desired, doses of 0.25 gm. twice weekly may be tried.

The Council voted to amend New and Nonofficial Remedies to describe these additional uses of acetazolamide.

Lederle Laboratories Division, American Cyanamid Company, cooperated by furnishing scientific data to aid in the evaluation of these additional uses of acetazolamide.

Nuclear Radiations in the Treatment of Cancer.—*Up to the* present moment, investigations with only two radioactive isotopes have given us important therapeutic applications in hyperplastic and neoplastic diseases through selective localization. These are radiophosphorus in the treatment of polycythemia vera and radioiodine in the treatment of the thyroid hyperplasia of Grave's disease and in the palliative treatment of certain thyroid cancers. However, one who has worked in the field from the beginning and who is asked to sum up his experiences can't help saying that the therapeutic achievements have been disappointing; but even in the early days we believed that the greatest contribution of radioactive isotopes in the field of medical and cancer research would lie in tracer applications, and we have devoted most of our energies to the latter. Even though the achievements in prolongation of life and cures in cancer have not been great so far, one should not dismiss too lightly the contributions of artificial radioactivity and nuclear radiations in cancer therapy. The clinician should not underestimate the importance of relief from pain and extension of comfortable life, and here their value is well established.–J. H. Lawrence and C. A. Tobias, Radioactive Isotopes and Nuclear Radiations in the Treatment of Cancer, *Cancer Research,* March, 1956.

AGING

Because of a progressive increase in the number of persons living beyond 60 years, more and more attention has been focused on the diseases to which they are especially prone and, more important, on ways of keeping them active and relatively healthy. In recognition of this, a Committee on Aging has been established in the A. M. A. Council on Medical Service (see this issue, page 210). Literally we start aging at the moment of conception and never stop until we die, but in the more usual sense aging starts when growth ceases. Lansing[1] defines aging as a process of unfavorable progressive change, usually correlated with the passage of time, becoming apparent after maturity and terminating in death. It is a gradual process, and Zimmerman[2] says that it represents a loss of functional reserve. One of the chief difficulties in studying this process is that no sure way is known at present to separate physiological sclerosis (the age-conditioned consolidation of tissues) from arteriosclerosis, to which it is not related histologically or pathogenetically. The concept that you are as old as your arteries does not get to the root of the matter, because aging is a process that can be recognized in plants and in animals that do not have arteries but in which a period of growth is followed by cessation of growth, decline, and death. Furthermore, Buerger and Hevelke[3] have shown that blood vessels in different organs age at different rates. Arteriosclerosis is also unevenly distributed in the body; thus the physiological process is masked by the pathological.

In man the main characteristics of aging are (1) tissue atrophy, the onset of which occurs at a different time and at different rates for different organs; as the oxygen supply to the tissues decreases the number and size of the cells also decreases; (2) gradual and partial replacement of more differentiated tissues by less differentiated tissue, e. g., hemopoietic tissue by fat in the marrow and interstitial fibrosis in various organs; and (3) deposition of pigment such as lipochromes in cells and of calcium in cartilage. Buerger and Hevelke studied the bradytrophic tissues, those tissues such as cartilage, crystalline lens, cornea, tympanic substantia propria, teeth, scar tissue, and the walls of the larger blood vessels, all of which have few if any capillaries. With age these tissues become dryer and denser. As their density increases, organic and inorganic inclusions appear and the tissue colloids become more concentrated. As these tissues become dryer, their nitrogen content decreases.

One of the questions regarding aging that is still unanswered is whether it is a property inherent in all living matter or whether it is related to physiological impairment in a specific organ or system such as the gonads. Shock[4] calls attention to the fact that all physiological processes do not deteriorate with age and cites examples: age induces no significant change in (1) the regulation of the acid-base equilibrium of the blood; (2) the fasting arterial blood sugar level (although there is an increase in the venous level); (3) the absorption of vitamin A; (4) the eosinophil response to corticotropin; or (5) the ability to retain nitrogen when given increased amounts of protein by mouth. Lansing believes that in senescence cellular permeability may be decreased due to an increase in the calcium content of the cell surface, but as yet there is no conclusive proof that this is the case. Shock has shown that with age there is a diminution in the renal plasma flow, loss of ability of the renal tubular cells to do osmotic work, and a decrease in the cardiac output at rest. Whether the changes that accompany aging are due to a reduction in the amount of active protoplasm in various organs or to reduced function of the protoplasm remaining is not known. In any case it has been shown that the aging of the blood vessels is accelerated by any increase in stress. Davidson[5] notes that elderly persons tend to lose interest in eating and that they eat foods high in carbohydrates and low in proteins, probably because these foods are easier to obtain, prepare, and chew, despite the fact that protein needs are not appreciably reduced with age. This may be a factor in accelerating the aging process.

One of the most important problems connected with aging is the determination of signs of mental deterioration, especially in business executives and persons in positions of responsibility. Birren[6] found that a test of writing speed differentiated more clearly between patients with senile psychosis and controls than did various combinations of standard mental tests. Flicker fusion tests at different levels of brightness showed a greater difference between old and young subjects as the level of brightness decreased. A battery of tests that would give a quantitative indication of the mental adaptability, judgment, and reasoning ability of aging executives could if properly used be of enormous benefit to business and to aging persons, many of whom are now forced to retire prematurely solely on the basis of their chronological age. Removal from positions of responsibility for signs of mental deterioration would also save companies from embarassment and should be a real service to the aging employee as well, freeing him in some cases to turn to a less taxing occupation and thereby prolonging his life.

PANORAMA OF MEDICAL RESEARCH

Much favorable comment has been evoked by the appearance of the two volumes "Medical Research: A Midcentury Survey," published under the auspices of the American Foundation.[1] They spread before the reader an exciting picture of the achievements of the past 50 years, in the medical sciences alone. If one adds to this some conception of the activity that has gone on in mathematics, physics, chemistry, biology, the earth sciences, and the social sciences, the result is overwhelming. Turning from the accomplishments of the past to the tasks and opportunities of the future is equally inspiring. Is it possible that research in social sciences may lead to so good a knowledge of man, so thorough a control of his impulses, as to eliminate poverty and crime? Will the accumulating data of experimental psychology conquer war and insanity? Will sociology tell us at last how to ensure the peaceable utilization of nuclear energy? In particular, will the medical sciences provide the physician with more of the tools he needs to battle disability and pain?

The facilities for research of all kinds now provided by individuals, by industries, by universities, by foundations, by the federal government, and by other organizations have become enormous; the annual expenditures are stated in terms of billions of dollars. Millions are spent on the development of a single new synthetic fiber. Market surveys determine the most effective color schemes for food packaging, and acoustic engineers produce phonographs so realistic that the listener can imagine himself in the midst of a symphony orchestra during its most exalted moments. Photographs of the buildings devoted to research and development by one automobile manufacturing company—"Main Research Building, Service Building, Manufacturing Development Building . . . Engineering Building, Styling Building and Styling Auditorium Dome facing 22-acre lake"—form a sort of polychromatic nocturne of forms and reflections, and the area houses more than 4,000 "scientists, engineers, stylists and technicians . . . within its twenty-five modern air-conditioned buildings."[2]

It would appear that the resources of science and engineering are inexhaustible. From television in color to new forms of plastics, from pesticides to fertilizers, from house paints to lubricants, the engineer seemingly has but to formulate his wishes and the research laboratory translates them into substance. The structure of any organic compound seems to be capable of an infinitude of variations, and there are corresponding differences, if the compound has value as a drug, in its principal action and its side-effects.

The second volume of "Medical Research" reminds the reader of the principal unsolved problems of clinical medicine, especially cancer. There is an urgency about these medical problems that perhaps is lacking in many industrial problems—the fact that promptness or delay in a medical discovery makes so great a difference in human lives. For instance, in 1953 "108,405 infants in the United States died before their first birthday."[3] Although the rate of infant mortality has been whittled down from a figure of 101.0 per 100,000 in 1916 to 27.8 in 1953, there are still nearly 300 deaths each day of children under the age of one year. Similarly, there were 16,399 deaths from cirrhosis of the liver in 1953. Although this disease is 12th from the top in the list of causes of death in the United States, it is claiming nearly 45 lives each day.[4]

Sudden breaks in the mortality from particular diseases have occurred within the experience of every research worker whose memory goes back to the days before sulfanilamide and penicillin. In 1922, before the announcement of the discovery of insulin by Banting and Best, there was a widespread conviction among scientists that the problem of making good extracts of pancreas was on the verge of solution. One young woman, rapidly losing ground because of severe diabetes, sat in her wheel chair every day on the veranda of a famous research institution and watched two students pass on their way to the laboratory. One day as they passed she asked them weakly when they were going to make the discovery that would save her. Embarrassed by a sense of the insignificance of their own contribution, the two students never forgot her earnest question. And to their joy, even though the discovery of insulin was made in another laboratory, it did come in time to save this patient.

Medical research is distinguished not only by the sense of urgency that motivates it but also by the fact that it unites men against a common enemy. The impulse to share with others whatever information has been gained by research, and the need to do so, is probably more keenly felt in medicine than in other branches of science. This is illustrated, for instance, by the common use of multiple or second languages for summaries of important articles. The obligation to publish important medical results and the policy of disseminating them in other languages might be considered in some ways as a counterpart to the ethical principle that forbids a physician to purvey secret remedies.

Thus there exists the machinery, all oiled and primed, for producing research and distributing its benefits—gigantic machinery that has already produced wonderful things. There will come moments when it needs fresh programs to work on. No suggestion, however trivial or capricious, should be overlooked if it leads investigators in new directions. Manufacturers of drugs and apparatus are eager for suggestions from medical men. The Rockefeller Institute for Medical Research has sponsored a series of conferences between physicians and manufacturers of apparatus of various kinds. The fifth conference, for instance, held on February 21, 1956, dealt with electronic instrumentation in surgery. In connection with apparatus for surgical diathermy, a manufacturer remarked that there seemed to be no limit to what could be supplied in the way of current forms and strengths provided the requirements were sufficiently definite and the costs were within reason. Never before has humanity seemed so close to realizing the hope of seeing "alabaster cities gleam, undimmed by human tears."

ORGANIZATION SECTION

A STATEMENT OF THE COMMITTEE ON AGING

At the June, 1955, session of the House of Delegates of the American Medical Association a resolution recommending the creation of a committee on geriatrics was adopted. As recommended, this committee was established under the Council on Medical Service. At the first meeting of the committee it became evident that the scope of its studies should be broader than the field inferred by the term geriatrics.

Unfortunately, geriatrics suggests the limited field of caring for the aged. It is a term that most serious students of aging avoid except to designate care of those far spent in their life content and activities. It probably has a certain utility but is not a stimulating title that can arouse the interest of members of the medical profession. After a thorough discussion, the committee recommended that its title be changed to that of Committee on Aging. This title was approved by the House of Delegates at the June, 1956, session.

Individuals, like institutions, may become obsolete—passé. Even then, these aged individuals have certain definite and important medical, housing, social, and emotional needs. Changes in the human body, in personality, and in social functions occurring as the individual grows and develops have introduced important new dimensions in medical science. As a result, problems of aging are multidimensional. As one national authority points out, these problems require not only a multiple disciplinary approach but also a correlating of diverse findings and planning for action. Information concerning the biological, psychological, and social processes bearing on the early years of human existence has increased our understanding of this period of human life. Control of the diseases, disorders, and deficiencies of the early years has created the opportunity for more and more individuals to live longer.

Gerontology concerns the scientific study of the phenomena of aging. All living matter changes with time in both structure and function, and the changes that follow a general trend constitute aging. Aging begins with conception and ends only with death. Growth, development, and maturation are thus a part of the aging process just as much as are atrophy and degeneration. The problems of gerontology extend from questions of changes in enzyme systems within individual cells to important social and economic problems of the interrelationships between aged people themselves and other members of society.

The medical profession has a unique opportunity, as well as an obligation, to study the medical, biological, psychological, and social aspects of growing older. Data concerning energy maintenance, fatigue control, and the preservation of specific motivation are needed. In the medical area the four most common disorders are (1) vascular deterioration, (2) cancer, (3) arthritis and rheumatism, and (4) mental disorders. Medical research should continue to study more and more the most common disorders of senior citizens.

Members of the medical profession should inform themselves of the great amount of study that has been devoted to problems of aging not only by physicians but also by sociologists, psychologists, social service workers, and political leaders. American medicine can play a practical and important part in enriching the lives of older citizens. Indeed, physicians should be expected to assume full leadership in all phases of this problem.

With some of these thoughts in mind the Committee on Aging has set forth the following objectives:

1. To explore problems concerned with the medical, biological, psychological, and social aspects of aging
2. To collect data concerning energy maintenance, fatigue control, and the preservation of specific motivation.
3. To promote research in these areas.
4. To inform the medical profession of the availability of information regarding the aging process.
5. To stimulate medical society interest in the problems of aging.
6. To impress upon the practicing physician the important role he can play by assuming community leadership to enrich the lives of older citizens.

HEALTH PLAN COMMISSION MAKES FIELD STUDIES

A subcommittee of the Commission on Medical Care Plans, appointed by the Board of Trustees of the American Medical Association in November, 1954, met in New York City June 29-July 1 to explore the possibility of conducting field studies of the many so-called independent plans having sponsors such as unions, management, and fraternal organizations. The committee members met with representatives of various medical societies to discuss local developments in

---

The members of the Committee on Aging are: Drs. Henry B. Mulholland, Chairman, Charlottesville, Va.; Edward L. Bortz, Philadelphia; Henry A. Holle, Austin, Texas; Wingate M. Johnson, Winston-Salem, N. C.; Theodore G. Klumpp, New York; Cecil Wittson, Omaha; and Frederick C. Swartz, Lansing, Mich.

this particular area of medical service. Committee members also visited several union health centers, management-sponsored health centers, and a number of group practice units connected with the Health Insurance Plan of Greater New York. Additional visits and conferences of this type are being planned by the subcommittee, the members of which are Drs. H. Russell Brown, Watertown, S. D., Chairman; John F. Conway, Clovis, N. Mex.; F. J. Elias, Duluth, Minn.; and Leo Price, New York. Working with the subcommittee in New York was Dr. Leonard W. Larson, Bismarck, N. D., a member of the Board of Trustees and Chairman of the Commission on Medical Care Plans. The Commission filed a progress report at the A. M. A. Clinical Session in Boston, which appeared in the Dec. 3, 1955, issue of THE JOURNAL, page 1370.

INAUGURATION FILM AVAILABLE

A 30-minute film recording of Dr. Dwight H. Murray's inauguration as President of the American Medical Association is available for showing to medical society audiences. The high-quality Kinescope of a local telecast includes the induction ceremony, Dr. Murray's inaugural address, and the presentation of the 1956 Distinguished Service award to Dr. Walter L. Bierring. The presidential inauguration took place during the Annual Meeting in Chicago, June 12.

WORLD MEDICAL ASSOCIATION CONVENTION

PROVISIONAL AGENDA

10TH GENERAL ASSEMBLY

THE

WORLD MEDICAL ASSOCIATION

held at

Latin American Culture House

Ave. de Los Presidentes and Calle Tercera

Havana, Cuba

October 9-15, 1956

OPENING SESSION

October 10th at 10:00 A. M. (1000)

WELCOME TO DELEGATES

1. Call to Order and Welcome to Delegates by DR. KARL NIEDERBERGER (Austria), President.
2. Greetings:

RETURN OF DELEGATES

3. Receive: The list of delegates, alternate delegates and observers appointed by member associations and other bodies. (Doc 33.1/56)

STANDING ORDERS

4. Adopt: Standing Orders of The World Medical Association

AMENDMENTS TO ARTICLES AND BY-LAWS

5. Consider: Adoption of Paragraph II and III of By-Law 19 (Constitution and By-Laws)
6. Consider: Amendment to Article 5, subsection (ii) and By-Law 2 (Doc 32.2/56)

ELECTION AND INSTALLATION OF PRESIDENT

7. Elect: President for 1956-57
8. Install: President for 1956-57
9. Presidential Address

PRESIDING OFFICER

10. Consider: Desire of President relative to election of a Presiding Officer (By-Law 18; Doc 32.50/56).

Should the President desire to evoke By-Law 18 during the 10th General Assembly the following items should be considered.

11. Consider: Presidential Nomination of member of 10th General Assembly to preside over the business transactions of the Assembly;
12. Consider: Confirmation by General Assembly of President's Nomination;
13. Install: Presiding Officer

GREETINGS

14. Greetings: Extended by the President to the Observers of international and national organizations in attendance. (Due to limitation of time and heavy business agenda of the General Assembly, International and National Observers will not be able to address the Assembly at this time.
    Organizations desiring messages extended to the 10th General Assembly are invited to transmit these to the Secretary General for inclusion in the Official Minutes.)

APPLICATION FOR MEMBERSHIP

15. Consider: Recommendations of the Council that applications of National Medical Associations approved by the Council be received into full membership in The World Medical

Association (Constitution and *By-Laws, Articles 4 and 5;* By-Laws 1, 2 and 15)
New Zealand Branch
) Doc 31.1/56
British Medical Association)

16. Receive: *Delegates*, and Alternate Delegates of New Member Associations.

MINUTES

17. Consider: Minutes of the 9th General Assembly held *in* Vienna, Austria, September 20-26, 1955, as compiled by the Secretary General and distributed (Doc 4.10/56) with the corrections received (Doc 4.10A/56)

ANNUAL REPORTS TO THE GENERAL ASSEMBLY

18. Consider: Annual Report of the Council to the General Assembly
Dr. Lorenzo Garcia-Tornel (Spain) Chairman of Council. (Doc 6.50/56)

19. Consider: Supplementary Report of the Council to the General Assembly (Doc 6.51/56)

20. Consider: Reports of Regional Secretaries

A. Asia	Dr. S. C. Sen (India) (Doc 7.10; 7.10A/56)
B. Australasia	Dr. J. G. Hunter (Australia) (Doc 7.20; 7.21/56)
C. Europe	Dr. P. Cibrie (France) (Doc 7.30/56C)
D. Latin America	Dr. Hector Rodriguez (Chile) (Doc 7.40; 7.40A/56)

21. Consider: Reports of Executive Editor and the *Editorial* Board of *World Medical Journal,* Dr. Austin Smith (USA) (Doc 9.1; 9.2/56)

22. Consider: Report of the Business Manager of *World Medical Journal,* Dr. Louis H. Bauer (USA) (Doc 9.10/56)

23. Consider: Annual Financial Reports
Reports of the Treasurer, Dr. Otto Leuch (Switzerland)

    A. Financial Statement as of December 31, 1955
    (Doc 5.1/56)

    B. Closing of accounts of 1955
    (Doc 5.2/56)

    C. Auditors Report for 1955 (*World Medical Journal,* September 1956, Page 204)

    D. Remarks of the Treasurer
    (Doc 5.3/56)

    E. Tentative Budget for 1957
    (Doc 5.5/56)

24. Receive: Annual Report of WMA Supporting Committees

    A. United States Committee, Inc.
    (Doc 5.10/56)

    B. Canadian Supporting Committee
    (Doc 5.50/56)

    C. Report of other supporting Committees

25. Consider: Council Committee Reports;

    A. Report of the Planning and Finance Committee, Dr. Otto Leuch (Switzerland) Chairman, (Doc 18.3/56)

    B. Report of the Medical Education Committee, Sir Lionel Whitby (UK) Chairman (Doc 11.2/56)

    C. Report of Miscellaneous Business Committee, Dr. Otto Rasmussen, (Denmark), Chairman (Doc 16.3/56)

    D. Report of Medical Ethics Committee, Dr. P. Glorieux, (Belgium), Chairman, (Doc 17.-/56)

    E. Report of International Liaison Committee, Dr. Jean Maystre, (Switzerland), Chairman (Doc 15.3; 15.4/56)

26. Consider: Report of Observers to other international organizations

    A. Dr. Jean Maystre (Switzerland)—Official Liaison Officer
        1. WHO (Doc 8.30; 8.30A/56)
        2. ISSA (Doc 8.32; 8.33/56)
        3. ILO (Doc)
        4. others ( )

    B. Dr. P. Cibrie (France)
    UNESCO and CIOMS (Doc 8.10/56)

    C. Dr. P. Glorieux (Belgium)
    International Congress of Military Medicine and Pharmacy

GENERAL ASSEMBLY COMMITTEE

27. Consider: Report of the General Assembly Committee on Social Security (Doc 10.1/56)

28. Receive: Report on The Role of the Medical Profession in any Medical Care Plan.

    A. *The Status of the Profession in Social* Security Schemes in Latin America, Dr. Hector Rodriguez (Chile) (Doc 10.2/56)

    B. Freedom of the Medical Profession and Medical Care Plans, Dr. Rolf Scholegell (Germany) (Doc 10.3/56)

MOTIONS FROM MEMBER ASSOCIATIONS

29. Consider: Motions from Member Associations

SELECTION OF MEETING PLACE AND ELECTION

30. Consider: Confirmation of Selection of Istanbul, Turkey, as venue of 11th General Assembly in 1957.

31. Consider: *Motion to* approve Council recommendation of Venue for 12th General Assembly in Copenhagen, Denmark, in 1958.

32. Election: Elect

    A. President-Elect 1956-57

B. Treasurer and Members of Council for three (3) years

Those whose terms expire in 1956 are:

Treasurer Dr. Otto Leuch (Switzerland)

Members of Council*

Dr. Lorenzo Garcia-Tornel (Spain)
Dr. Gunnar Gundersen (USA)
Dr. A. Mantellos (Greece)
*Dr. S. C. Sen (India)

*A regional vacancy exists in the Asiatic area and must be filled by a candidate from that area. The other three vacancies can be filled from any area.
(Doc 60.1; 60.2; 60.3; 60.4/56)

NEW BUSINESS

33. Consider: Any New Business

MINUTES

34. Consider: Motion that the Secretary General be empowered to prepare the Minutes of the 10th General Assembly for distribution subject to correction at the 11th General Assembly.

ADJOURNMENT

35. Consider: Motion for adjournment.

AGENDA
OF
SEVENTH ANNUAL CONFERENCE
OF
MEDICAL EDITORS

Latin American Culture House

Ave. de Los Presidentes and Calle Tercera

Havana, Cuba

October 11, 1956

9:30 A. M.–12:00 Noon

(0900–1200)

Chairman: Dr. Saturnino Picaza Del Pino
Director of Journal; *Annals of the Academy of Physical, Natural and Medical Sciences of Havana.*

Secretary: Dr. Austin Smith (USA)
Editor, *World Medical Journal* and *Journal of the American Medical Association.*

Subject: *Pan American Medical Publication Problems*

A cordial invitation is extended to all delegates, alternate delegates and observers to the 10th General Assembly to attend this meeting. The problems to be considered are not limited to Editors of Medical Publications, the practicing Doctor as the "Consumer" and "Contributor" to medical journals will be interested in the topics developed at this meeting.

I

LATIN AMERICAN PROBLEMS IN EDITING MEDICAL JOURNALS

by

Dr. Agustin Delacroix, h (Argentina)
Director: *Journal of the Argentina Medical Confederation*

Discussants: Dr. Ernst Fromm (Germany)
Hamburger Arzteblatt
Dr. Yasusaburo Sugi (Japan)
Journal of Japan Medical Association

General Discussion

II

THE SCIENTIFIC MEDICAL ARTICLE AND MEDICAL ETHICS

by

Dr. Rafael Lopez Ruiz (Colombia)
Editor: *Pan American Medical Confederation Journal*
Former Director: *Heraldo Medico*

Discussants: Dr. Felix Worré (Luxembourg)
Bulletin du Syndicat Medical
Dr. Viljo Rantasalo (Finland)
Finland Lakartidning

General Discussion

III

THE PAN AMERICAN CONFEDERATION JOURNAL AS A MEANS OF MEDICO-SOCIAL ADVANCEMENT IN LATIN AMERICA

by

Dr. Leopoldo E. Araujo (Cuba)
Editorial Board Member: *Pan American Medical Confederation Journal.*

General Discussion

IV

Consider: Any other business or discussion

V

Adjournment

LUNCHEON

A Luncheon, sponsored by the Nepera Chemical Company, Yonkers, New York, with Mr. Milton Lasdon as the Host will be held at the close of the meeting.
Participants in the Seventh Medical Editor's Meeting are invited to attend this Luncheon.

Reservations for the luncheon must be made in advance.

SCIENTIFIC PROGRAM
AT
10TH GENERAL ASSEMBLY

Latin American Culture House

Havana, Cuba

Friday, October 12, 1956

9:30 A. M.–1:00 P. M.

(0930–1300)

Chairman: Dr. Vicente Banet Pina
Professor of Clinicial Surgery, University of Havana.

I

SYMPOSIUM
PATHOLOGY IN PREMATURITY

A. *Causes of Death of the Premature in Cuba*

1. Dr. Emilio Soto Pradera
Member of the Cuban Pediatrics Society; Havana Society of Clinical Studies; American Academy of Pediatrics.

2. Dr. Federico Fuste Amieba
Pathologist, Obrera Maternity Clinic of Havana and Cuba Mental Hospital; Member of the Cuban Pediatrics Society.

3. Dr. Jose R. Montalvo
Member of the Cuban Pediatrics Society and the American Academy of Pediatrics.

B. *Infections of the Premature Infant*

1. Dr. Rene Montero De La Pedraja
Fellow–American Academy of Pediatrics

2. Dr. Carlos Montalvo Sotolongo
Professor of Pediatrics, University of Havana, School of Medicine; Staff Member–Havana Municipal Hospital for Children.

3. Dr. Jorge Beato Nunez
Instructor of Pediatrics, University of Havana, School of Medicine.

C. *Erythroblastosis and Kernicterus*

1. Dr. Serafin Falcon Lopez
Chief of Service of the Municipal Infants and Maternity Hospital of Havana "America Arias"; Member of the Cuban Pediatrics Society, the French Pediatrics Society and the American Academy of Pediatrics.

2. Dr. Julio Cornejo Gonzalez
Professor of Pediatrics at Our Lady of Mercy Hospital; Member of the Cuban Pediatrics Society.

3. Dr. Juan Bencomo Garcia
Chief of Blood Bank Municipal Maternity Hospital "America Arias" and Chief of Laboratories of General Pathology. Professor of Summer School at the University of Havana, School of Medicine.

4. Dr. Israel Borrajero
Pathologist, Municipal Maternity Hospital "America Arias," Havana.

D. *Hemorrhagic Disturbances of the Premature*

1. Dr. Angel A. Aballi Garcia Montes
Associate Professor, Faculty of Medicine, University of Havana; Member of Havana Society of Clinical Studies and Cuban Pediatrics Society.

2. Dr. Valeriano Lopez Banus
Staff Member, Infant and Maternity Division of University Hospital "General Calixto Garcia"

3. Dr. Sergio De Lamerens Zayas
Professor of Pediatrics, University of Havana, School of Medicine.

4. Dr. Israel Borrajero
Pathologist, Municipal Maternity Hospital "America Arias," Havana.

II

SYMPOSIUM
CARDIOVASCULAR SURGERY

A. *Cardiovascular Surgery in Cuba*

Professor Vicente Banet Pina, Past President–Nacional Medical College; Professor of Clinical Surgery, University of Havana, School of Medicine; Member of Havana Academy of Physical, Natural and Medical Sciences.

B. *Tetralogy of Fallot*

1. Dr. Agustin Castellanos
Professor of Pediatrics, University of Havana; Director, Municipal Hospital for Children.

2. Dr. Angel Giral Casielles
Member of Executive Committee, National Medical College. Chief Surgeon, Cardiovascular and Chest Disease, Municipal Childrens Hospital.

C. *Pulmonary Stenosis*

1. Dr. Rodrigo Bustamante, M. R. C. P. (EDIN)
Cardiologist–University Hospital and "Lila Hidalgo" Hospital.

2. Dr. Armando Nunez Nunez
President–Cuban Angiology Society

D. *Inter-Auricular Communication*

1. Dr. Otto Garcia Diaz
Internist–Municipal Children's Hospital of Havana.

2. **Dr. Antonio Rodriguez Diaz**
Director—Institute of Cardiovascular and Chest Surgery.

E. *Mitral Stenosis*

1. **Dr. Frank Barrera**
Former Instructor, Temple University of Philadelphia; Chief—Department of Cardiology and Experimentation, Institute of Cardiovascular and Chest Surgery.

2. **Dr. Hilario Anido**
Chief Surgeon, Institute of Cardiovascular and Chest Surgery; Secretary National Society of Surgery.

F. *Anesthesia in Cardiovascular Surgery*

Dr. Francisco Gutierrez Pelaez
Anesthesiologist—Municipal Maternity Hospital "America Arias" and Cardiovascular Surgeon, Institute of Cardiovascular and Chest Surgery.

Travel Information

HAVANA, CUBA

Population: 674,376 Altitude: Sea level

Immigration. U. S. citizens require proof of nationality, round trip ticket or onward transportation, and documentation to country beyond Cuba.

Note: A passport is required of U. S. citizens who are racially Chinese. A smallpox certificate, not less than 8 days nor more than 3 years old, is required for return to the U. S.

General Information:

Language—Spanish. English is generally spoken by those in public activities. Special English-speaking police are on hand to help tourists.

Havana—The capital of Cuba, is a city of fun, sunshine and sociability.

Hotels—There are nine leading hotels in Havana, they are luxurious, beaches fine, food and drink among the best in the world. Everything is done to make your stay enjoyable. Almost all hotels have laundry and dry cleaning service.

Church—There are churches of nearly all major denominations, as well as a synagogue.

Climate—The temperature ranges from an average of 72° in January to an average high of 82° in July and August.

Currency—Monetary unit is the Peso—on a par with the U. S. dollar. Business travelers may take out of Cuba only $50.00 U. S. currency. All excess must be in travelers checks, money orders, etc.

Duty Free Imports—Tobacco, no restrictions—Cameras, no restrictions—Liquor, no restrictions.

1. Dr. Rodrigo Bustamante, M. R. C. P. (EDIN)
Cardiologist–University Hospital and "Lila Hidalgo" Hospital.

2. Dr. Armando Nunez Nunez
President–Cuban Angiology Society

D. *Inter-Auricular Communication*

1. Dr. Otto Garcia Diaz
Internist–Municipal Children's Hospital of Havana.

will speak on "Life Among the World Planners." The Kentucky Society of Anesthesiology will have as guest speaker Dr. Charles R. Stephen, Durham, N. C., who will discuss "Ventilation in Anesthesia." Dr. Louis A. Buie, Rochester, Minn., will consider "Office Practice in Proctology" before the Kentucky Academy of General Practice. The Kentucky Obstetrical and Gynecologic Society has scheduled a round table on obstetric difficulties, for which Dr. V. Edward Masters, Louisville, will serve as moderator. The scientific sessions will end Thursday afternoon with a panel discussion on upper gastrointestinal bleeding, moderated by Dr. Rudolf J. Noer, Louisville. An innovation at the annual meeting will be the presentation of scientific movies and of postgraduate refresher courses, including "The Management of Trauma," "Common Problems in Infants and Children," and "A Medical Symposium." The registration fee is $5. The woman's auxiliary will meet concurrently.

MASSACHUSETTS

Traineeships in Adolescent Care.—The Adolescent Unit at the Children's Hospital, 300 Longwood Ave., Boston 15, offers a general practice type of postgraduate training in the care of adolescents. A limited number of one-year traineeships are available to properly qualified physicians who have had two or more years of hospital experience after graduation from medical school. The teaching staff, including a gynecologist, endocrinologist, gastroenterologist, cardiologists, and psychiatrists, is directed by Dr. James R. Gallagher, to whom any inquiries should be sent.

Institute of Psychiatric Treatment.—The fourth annual Institute of Psychiatric Treatment will be presented in the Reception Building of the Boston State Hospital, Sept. 27-29, under the direction of Drs. Leo Alexander and Robert E. Arnot. Presentations by out-of-state speakers will include:

Ambulatory Treatment with Tranquilizing Drugs, Frank J. Ayd Jr., Baltimore.
Role of the Conditional Reflex in the Mechanism of Mental Illness and Therapy, W. Horsley Gantt, Baltimore.
Psychotherapy, Hans Lowenbach, Durham, N. C.
Demonstrations: Electric Sleep, Paul H. Wilcox, Traverse City, Mich.
Clinical Use of the New Drugs, Including Chlorpromazine and Reserpine, in the Major Psychoses, Nathan S. Kline, New York City.
Hypnosis (with clinical demonstration), Milton H. Erickson, Phoenix, Ariz.

Cocktails and dinner at the Harvard Club have been scheduled for 6:30 p. m. Friday. A review of experiences in organizing a treatment and research service at the Philadelphia State Hospital will be presented by Dr. Irving M. Rosen. The registration fee for the institute is $35. Further information may be obtained from Dr. Alexander at 433 Marlborough St., Boston.

MICHIGAN

Increase in Typhoid.—The Michigan Department of Health reports that the number of typhoid cases in Michigan is larger than at any time in the last 10 years. The number of cases in Michigan from January through Aug. 10 was 39, an increase of 24 over the same period in 1955 and the highest incidence since 1947. All typhoid cases reported in Michigan during 1956 have occurred in the lower peninsula, where they have been distributed evenly with no concentration by localities.

State Medical Meeting in Detroit.—The 91st annual session of the Michigan State Medical Society will convene Sept. 26-28 at the Sheraton-Cadillac Hotel, Detroit, under the presidency of Dr. William S. Jones, Menominee. On Wednesday, which has been designated General Practice Day, the following presentations will be made:

Perry S. MacNeal, Philadelphia, Diseases of the Adrenal Gland.
Francis R. Keating Jr., Rochester, Minn., Clinical Problem of Primary Hyperparathyroidism.
Seward E. Miller, Washington, D. C., The GP in Chronic Disease and Disabilities in Industry.
John K. Lattimer, New York, Chemotherapy of Renal Tuberculosis.
John P. Caffey, New York, Infantile Cortical Hyperostosis: Chronic and Prenatal Types.
Somers H. Sturgis, Boston, Psychosomatic Aspects of Gynecology.
Edwin J. DeCosta, Chicago, The Thyroid Gland in Pregnancy.
Otis L. Anderson, Washington, D. C., Chronic Disease, a Challenge to the Medical Profession.

The Thursday session will open with a surgical panel on thyroid diseases, moderated by Dr. Frederick A. Coller, Ann Arbor, with Drs. Dwight E. Clark, Chicago, E. Perry McCullagh, Cleveland, and James H. Means, Boston, as participants. Dr. G. Slaughter Fitz-Hugh, Charlottesville, Va., will then present "Indications for Tracheotomy" and Dr. John R. Schenken, Omaha, "The Cystic Ovary—Surgical or Nonsurgical?" After the William Beaumont, M.D., Annual Lecture, "Clues and Pitfalls in the Diagnosis of Jaundice," by Dr. Leon Schiff, Cincinnati, Dr. Theodore F. Schlaegel Jr., Indianapolis, will discuss "The Etiology and Diagnosis of Endogenous Uveitis"; Dr. Warren E. Wheeler, Columbus, Ohio, "Bacterial Disease in the Newborn"; and Dr. M. Ralph Kaufman, New York, "Psychotherapies in a General Hospital." The Friday assembly will hear the following papers:

LeRoy A. Calkins, Kansas City, Kan., Prolonged Labor.
Averill A. Liebow, New Haven, Conn., Some Aspects of Diagnosis of Lung Tumors and Cancer.
Herbert Rattner, Chicago, The Art of Topical Therapy.
Edward P. Cawley, Charlottesville, Va., Milkers' Nodules.
Kenneth E. Appel, Ardmore, Pa., Medical and Psychiatric Collaboration—Importance and Possibility.
O. Sidney Orth, Madison, Wis., Physician Alertness to Altered Physiology During Anesthetization.

Discussion conferences (12-1 p. m.) have been scheduled daily. They will be led Wednesday by Dr. Harold C. Mack, Detroit, Thursday by Dr. Frederick A. Coller, Ann Arbor, and Friday by Dr. Harold Henderson, Detroit. The general sessions will end Friday afternoon with a cross country panel on Cardiovascular Diseases, for which Dr. John M. Murphy, Detroit, will serve as moderator. Drs. Arthur C. Corcoran, Cleveland, George R. Meneely, Nashville, Tenn., Charles A. Poindexter, New York, and Myron Prinzmetal, Beverly Hills, Calif., will participate. On Wednesday at 6:30 p. m. the officers' night reception will precede the informal banquet, honoring officers of the Michigan State Medical Society and its woman's auxiliary. The president's annual address and the Andrew P. Biddle Lecture will be delivered that evening. The Michigan State Medical Assistants Society will meet Sept. 26-27 for a program that will include presentations by Dr. James D. Fryfogle, Detroit, ("Facts and Figments of Heart Surgery") and Dr. W. W. Bauer, Chicago, Director of the American Medical Association Bureau of Health Education ("Stop Annoying Your Patients"). The woman's auxiliary will meet concurrently with the parent organization.

MINNESOTA

Society News.—The Minnesota chapter of the Arthritis and Rheumatism Foundation recently named Dr. Cecil J. Watson, Minneapolis, president; Dr. Charles H. Slocumb, Rochester, vice-president; and Dr. John M. Wolff, Duluth, second vice-president.——The Twin City Radiological Society was recently organized by radiologists active in St. Paul and Minneapolis. The organization will hold quarterly meetings. Dr. Cyrus O. Hansen, Minneapolis, was elected chairman and Dr. Leo A. Nash, St. Paul, secretary.

NEW YORK

Society News.—Dr. Thurman B. Givan, Brooklyn, president-elect of the Medical Society of the State of New York, will be the principal speaker during the dinner at the annual meeting of the eighth district branch of the state medical society, Sept. 27 at the Bartlett Country Club, Olean. The scientific session, 2-5 p. m., will include the following presentations by guest speakers:

Cytologic Diagnosis of Malignancy, Thomas R. Simon, director of cytology, Memorial Center for Cancer and Allied Diseases, New York City.
The Tranquilizing Drugs, George B. Koelle, professor of pharmacology, University of Pennsylvania Graduate School of Medicine, Philadelphia.
The Surgical Risk in Patients with Cirrhosis of the Liver, Woodrow W. Lindenmuth, chief of surgical service, Veterans Administration Hospital, West Haven, Conn.

New York City

Visiting Professor of Physiology.—Dr. Jose del Castillo of London, England, has been appointed visiting professor of physiology at the State University of New York College of Medicine at New York City, Brooklyn, for one year, beginning on Sept. 1. A professor in the department of biophysics at University College, London, Dr. del Castillo has been on the faculties of the University of Salamanca, Spain; Middlesex Hospital Medical School, London; and the University of Bern, Switzerland.

Conference on Rehabilitation.—Rehabilitation of sick and injured workers will be the subject of a conference called by Miss Angela R. Parisi, chairman, New York State Workmen's Compensation Board, at the Sheraton-Astor Hotel, Sept. 27. Participants in the conference will include Dr. Paul H. Hoch, New York state commissioner of mental hygiene; Dr. Howard A. Rusk, director, Institute for Physical Medicine and Rehabilitation; Dr. Henry H. Kessler, director of the Kessler Institute, West Orange, N. J.; Assemblyman John Ostrander, chairman, joint legislative committee on industrial and labor conditions; Mr. Joseph Shaw, Associated Industries of the State of New York; and Mr. Thomas Jefferson Miley, president of the Commerce and Industry Association.

OHIO

Meeting of General Practitioners.—The sixth annual scientific assembly of the Ohio Academy of General Practice will be held in the new Franklin County Veterans Memorial Auditorium, Sept. 19-20. The banquet will be at the Deshler-Hilton Hotel Wednesday. Presentations by out-of-state speakers during the scientific sessions will include:

Trends in Pediatric, Adult, and Geriatric Nutrition, Thaddeus D. Labecki, Jackson, Miss.
Herniated Lumbar Intervertebral Disk Problem, Harold R. Oberhill, Chicago.
Abnormal Uterine Bleeding, Frederick H. Falls, Chicago.
Management of Congestive Heart Failure, E. Hugh Luckey, New York.
Cancer Detection in the Office of the Generalist, John S. DeTar, Milan, Mich.
Office Management of Leukorrheas, Leslie V. Dill, Washington, D. C.
Treatment and Prevention of Lateral Rotation of Legs and Flatfeet in Small Children, Joseph H. Kite, Atlanta, Ga.
Psychotherapy in General Practice, Vernon P. Williams, Boston
Hypnosis for the General Practitioner, Seymour Hershman, Chicago.
Premalignant Lesions of the Rectum and Colon, Charles W. Mayo, Rochester, Minn.

RHODE ISLAND

Hospital Reunion.—The reunion of former interns, residents, and fellows of the Rhode Island Hospital, Providence, is scheduled for Sept. 28-29. Plans are being formulated for professional programs at the hospital on Friday morning and afternoon and on Saturday morning. The main social event will be a shore dinner at the Squantum Club for the homecomers and their wives.

VIRGINIA

Society News.—The Virginia Society of Ophthalmology and Otolaryngology recently elected Dr. L. Benjamin Sheppard, Richmond, president; Dr. Emanuel U. Wallerstein, Richmond, president-elect; Dr. Calvin T. Burton, Roanoke, vice-president; and Dr. Maynard P. Smith, Richmond, secretary-treasurer.

Personal.—At its annual meeting the Virginia Tuberculosis Association bestowed on Dr. Charles P. Cake, Washington, D. C., the Douglas Southall Freeman award for his efforts in tuberculosis control. Dr. Cake, who is president of the Southern Tuberculosis Association, is a past president of the Arlington County Medical Society, the Community Chest, Metropolitan Washington TB Conference, Virginia Trudeau Society, and the Swanson Parent-Teacher Association. During World War II he served as chief of the tuberculosis division, U. S. Public Health Service Hospital, Staten Island, N. Y.

Conference on Obstetrics and Gynecology.—The University of Virginia School of Medicine, Charlottesville, will have a Conference on Obstetrics and Gynecology Sept. 28. Guest speakers include Dr. Charles H. Mauzy, associate professor of obstetrics and gynecology, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C.; Dr. Robert A. Kimbrough Jr., chairman, department of obstetrics and gynecology, University of Pennsylvania Graduate School of Medicine, Philadelphia; and Dr. Andrew A. Marchetti, professor of obstetrics and gynecology, Georgetown University School of Medicine, Washington, D. C.

WASHINGTON

Symposium on Heart Disease.—The eighth annual Symposium on Heart Disease will be presented Sept. 28-29 at the University of Washington Medical School Auditorium in Seattle by the Washington State Heart Association and the Washington State Department of Health. The themes of the symposium, "Peripheral Vascular Disease" and "Congenital Heart Disease," will be developed in papers, panel sessions, and question periods by the following speakers: Drs. Frederic H. Bentley, Portland, Ore., S. Gilbert Blount Jr., Denver; Denton A. Cooley, Houston, Texas, C. Walton Lillehei, Minneapolis; and J. Lowell Orbison, Rochester, N. Y. The symposium is in category I of the Academy of General Practice; credit can be earned hour for hour for attendance. There will be no registration fee. The Minnesota football game will be played at the University of Washington on Saturday.

WEST VIRGINIA

Hospital News.—Dr. Robert G. Blackwelder, Marion, Va., has been appointed superintendent of the Andrew S. Rowan Memorial Home at Sweet Springs, succeeding Dr. Edward E. Rose, formerly of Huntington, who resigned because of ill health. Dr. Blackwelder served as a member of the staff at Huntington State Hospital in Huntington from 1933 until 1939. Since October, 1954, he has been clinical director of the Southwestern State Hospital at Marion. He has also served as superintendent of the State Hospital at Raleigh, N. C., and of the Eastern Shore State Hospital at Cambridge, Md.

Society News.—Mr. Oliver Matthews, Kingwood, was recently elected president of the West Virginia Public Health Association, Dr. Bruce H. Pollock, Huntington, first vice-president, Mrs. Oletta M. Riffe, second vice-president; and Mrs. Katherine L. Brown, treasurer.——At the annual meeting of the West Virginia chapter of the American College of Surgeons Dr. Charles M. Scott, Bluefield, was elected president; Dr. Charles D. Hershey, Wheeling, vice-president; and Dr. Kenneth G. MacDonald, Charleston, secretary-treasurer.——The annual regional meeting of the West Virginia chapter of the American College of Physicians will be held at the Daniel Boone Hotel in Charleston, Sept. 29. The scientific session will open with "Acryoglobulin with Unusual Characteristics Associated with a Rare Hematological Disorder" by Dr. Edgar L. Crumpacker, Mary L. Petermann, Ph.D., and Dr. W. D. Irvine, the Greenbrier Clinic, White Sulphur Springs. It will close with "Coal Workers' Pneumoconiosis" by Dr. Peter P. Ladewig, pathologist, Laird Memorial Hospital, Montgomery. A cocktail party at 6 p. m. will precede dinner, 7 p. m., at the Edgewood Country Club. The guest speaker will be an officer of the American College of Physicians.

GENERAL

Conference on Occupational Therapy.—The 1956 conference of the American Occupational Therapy Association will be held Sept. 29–Oct. 5 at the Nicollet Hotel, Minneapolis. The theme of the conference will be "Time for Reflection," and the topics will include: Occupational Therapy in Relation to General Medicine and Surgery, Geriatrics, Pediatrics, Physical Disabilities, and Psychiatry.

Mid-Continent Psychiatric Association.—The Mid-Continent Psychiatric Association will hold its annual meeting at the Velda Rose Motel, Hot Springs, Ark., Sept. 21-23 under the presidency of Dr. Harold W. Sterling, North Little Rock, Ark. Members of the Arkansas Psychiatric Society will act as hosts. Speakers will include Dr. Nathan W. Ackerman, New York City, Dr Ewing H. Crawfis, Cleveland; Dr. Leopold N. Judah, North Little Rock, Ark.; Dr. Jules H. Masserman, Chicago, Dr. Richard C. Proctor, Winston-Salem, N. C.; Drs. William G. Reese, Terry C. Rodgers, and William P. Kolb, Little Rock, Ark.; Dr. Martin L. Towler, Galveston, Texas; Dr. Jack P. Whisnant, Rochester, Minn., and Dr. Charles D. Yobe, Hot Springs National Park, Ark.

Medical Writers Association Meeting in Chicago.—The American Medical Writers' Association will hold its 13th annual meeting at the Hotel Morrison, Chicago, Sept. 28 and its workshop

Sept. 29. Dr. Dwight H. Murray, Napa, Calif., President of the American Medical Association, will address the evening meeting, which will be preceded by a social hour (compliments of the Schering Corporation). Other speakers will include:

Austin E. Smith, Chicago, Role of an Official Journal.
Johnson F. Hammond, Chicago, The Make-Up of the J. A. M. A.
Mr. Gilbert S. Cooper, Chicago, Tables and Illustrations.
Mr. L. B. Murdock, Chicago, Problems of the Medical Manuscript Editor.
Morris Fishbein, Chicago, The Editorials of Medical Journals.
Harold Swanberg, Quincy, Ill., The A. M. W. A. Manuscript Editing Service.
Paul D. White, Boston, Experiences with Science Writers, Medical and Lay, and with the Press.
Alton Blakeslee, B.A., New York, Interpreting Medical Science for the Public.
Jonathan Forman, Columbus, Ohio, Workshops in Medical Writing for Medical Societies.
Sholom O. Waife, Indianapolis, Problems and Prospects in Specialty Journal Editing.
Jacques P. Gray, Detroit, The A. M. W. A. Visiting Lectureship.

Mississippi Valley Medical Meeting.—The 21st annual meeting of the Mississippi Valley Medical Society will convene at the Hotel Morrison, Chicago, Sept. 26-28 under the presidency of Dr. Frank R. Peterson, Cedar Rapids, Iowa. The principal banquet speaker will be Dr. Dwight H. Murray, Napa, Calif., President of the American Medical Association. Also scheduled as banquet speakers are Dr. Wendell L. Downing, LeMars, Iowa, president, Iowa State Medical Society; Dr. F. Lee Stone, Chicago, president, Illinois State Medical Society; and Dr. Lien O. Simenstad, Osceola, Wis.; president, Wisconsin State Medical Society. Dr. Martin A. Seidell, Urbana, Ill., winner of the 1956 Mississippi Valley Medical Society essay contest, will present "A Compendium for Fluid and Electrolyte Management with Ordinary and Extraordinary Laboratory Facilities." The following panels will be offered:

Osseous Trauma—Fractures: Modern Concepts of Treatment (Samuel W. Banks, Chicago, moderator).
Gynecology (J. P. Greenhill, Chicago, moderator).
Thyroid Diseases (Arnold S. Jackson, Madison, Wis., moderator).
Recent Advances in Diagnosis and Therapy (John F. Sheehan, Chicago, moderator).
Arthritis and Rheumatic Disease (Charles H. Slocumb, Rochester, Minn., moderator).
Coronary Thrombosis (Paul D. White, Boston, moderator).

A cocktail party (courtesy of Chas. Pfizer & Co.) will precede, and the president's reception will follow the informal banquet.

Pediatricians Meet in New York.—The American Academy of Pediatrics will hold its 25th annual meeting at the Hotel Statler, New York, Oct. 6-11 under the presidency of Dr. Harry Bakwin, New York. Ten seminars have been scheduled for Saturday and Sunday and 20 round-table discussions for Monday through Wednesday. The general session will open Monday at 9:30 a.m. with a panel on obesity, moderated by Dr. Harry H. Gordon, Baltimore. Dr. Edith H. M. Lincoln, New York, will serve as moderator for a symposium on tuberculosis at 2 p.m. A symposium on genetics and disease (Dr. Barton Childs, Baltimore, moderator) will open the Tuesday morning session. On Wednesday morning, Dr. Paul R. Swyer, Toronto, Canada, will speak on hiatus hernia and Seymour Heymann, M.B., Johannesburg, South Africa, on the medical treatment of congenital hypertrophic pyloric stenosis. A panel discussion on adolescence will be presented Thursday morning (Dr. Waldo E. Nelson, Philadelphia, moderator). Thursday afternoon will be devoted to clinical sessions at various hospitals. The price of admission, $1.00, will include bus transportation from the Hotel Statler to the hospitals and return. The committee on adoptions has announced that its panel on adoptions Monday evening will be open to everyone interested in this discussion. The social program includes a special symphony concert at Hunter College Auditorium, Tuesday, 8:30 p. m.; a reception and cocktail hour (courtesy of Mead Johnson & Company) preceding the banquet Wednesday, 8 p.m.; an International Food Festival (Courtesy of Beech-Nut Packing Company) Monday and Tuesday; a welcome hour (courtesy Ross Laboratories) Sunday, 6-7:30 p.m.; breakfast (courtesy Libby's Baby Foods) Tuesday, 7-8:45 a.m.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

Annual Clinical Conference.—The Kansas City Southwest Clinical Society will present its 34th annual Fall Clinical Conference Sept. 24-27 at the Municipal Auditorium, Kansas City, Mo. The fourth Edward Holman Skinner Memorial Lecture, "The Direction of Effort in Malignant Disease," will be delivered by Dr. Isidor S. Ravdin, Philadelphia, on the opening day. Other guest speakers and their first presentations include:

William A. D. Anderson, Miami, Fla., Tumors of Childhood.
B. Marden Black, Rochester, Minn., Continence-Preserving Procedures for Carcinoma of the Upper Rectum and R 'gmoid.
George Crile Jr., Cleveland, Carcin . 'reast—the Surgeon's Dilemma.

Urban H. Eversole, Boston, Safeguarding the Surgical Patient.
Edgar Hull, New Orleans, Emergency Use of Corticoids and Corticotropins.
Chevalier L. Jackson, Philadelphia, What Can the Broncho-Esophagologist Do for the General Practitioner?
Laurance W. Kinsell, Oakland, Calif., Observations on Use of the Insulin-Sparing Sulfonamides.
John M. Lyon, Denver, Diagnostic and Treatment Suggestions in Psychoneurotic Reactions.
Walter G. Maddock, Chicago, Differential Diagnosis of Jaundice
Carl V. Moore, St. Louis, Thrombocytopenic Purpura, Its Pathogenesis and Treatment.
LeRoy H. Sloan, Chicago, Bedside Neurology in Daily Practice.
E. Stewart Taylor, Denver, Cervical Carcinoma in Situ.
Don C. Weir, St. Louis, Accuracy and Limitations of Diagnostic Roentgenology.
Ben J. Wilson, Dallas, Texas, Treatment of Shock (Dangers and Complications of Nonspecific Therapy).

Panel discussions have been scheduled on Tumors of the Neck, Diagnosis and Management of Bone Disease. Recent Advances in Medicine and Surgery; Fluid and Electrolyte Balance, Common Types of Anemia; and Functional Gastrointestinal Disorders. Color television programs will be presented on Herniorrhaphy; Goiter Clinic; Caudal Anesthesia; Tracheotomy; Arthritis Clinic, Cesarean Section; Cholecystectomy; and Blood Transfusion. A clinical pathological conference is scheduled for Monday. Daily round-table luncheons have been scheduled with the distinguished guests. On Thursday Dr. Hubert M. Parker, Kansas City, Mo., will serve as moderator for a combined medical and surgical luncheon, closing with a panel discussion, "Recent Advances in Medicine and Surgery."

American Hospital Association.—The 58th annual convention of the American Hospital Association will be held at the International Amphitheatre in Chicago, Sept. 17–20. The Palmer House will be the headquarters hotel. The general sessions will open Monday afternoon with "What Are the Needs?" by Drs. Theodore G. Klumpp, New York, and Jack R. Ewalt, Boston. This presentation will be followed by "What Are the Resources?" by Dr. Lowell T. Coggeshall, special assistant for health and medical affairs to the Secretary of Health, Education, and Welfare, Washington, D. C., and Mr. George Bugbee, president, Health Information Foundation, New York. The president's reception and tea dance Monday, 6–9 p.m., will honor Dr. Albert W. Snoke, New Haven, Conn., president-elect. There is no charge, and everyone is welcome. At the federal luncheon Tuesday, 12:15 p.m., arranged for representatives of federal hospitals but open to all other convention registrants, the speaker will be Marion B. Folsom, Secretary, Department of Health, Education, and Welfare, Washington, D. C. Tickets are $3.50. The Conference on Hospital Planning Wednesday morning will be presented by the association in joint sponsorship with the American Association of Hospital Consultants, American Association for Hospital Planning, and American Institute of Architects. The general session Wednesday afternoon will be devoted to a program on "Meeting the Needs," which will have as participants Drs. Howard A. Rusk, New York, Joseph N. Schaefler, Peoria, Ill., Leonard O. Bradley, Winnipeg, Manitoba, Canada, and Daniel Blain, Washington, D. C. At the banquet Wednesday evening, presentation of the distinguished service award to Dr. Charles F. Wilinsky, Boston, will follow presentation of honorary memberships to Dr. George F. Lull, Secretary-General Manager, American Medical Association, Chicago, Dr. Theodore G. Klumpp, chairman, Hoover commission task force on medical services, and president, Winthrop Laboratories, New York, and Emory W. Morris, D.D.S., president and general director, W. K. Kellogg Foundation, Battle Creek, Mich. A session on planning for disaster will be held at the Stock Yard Inn Thursday morning. The general sessions will end Thursday afternoon with a program on Hospital Professional Relations at which Dr. Dwight H. Murray, Napa, Calif., President of the American Medical Association, will speak for the physician.

FOREIGN

Congress of the History of Medicine.—The 15th International Congress of the History of Medicine will hold its biennial meet- in Madrid and Salamanca in Spain, Sept. 21–28. The provisional program lists the following papers: "American Indian Medicine in North America," "Daniel Le Clerc's Histoire de la Medicine," and "Iconography of the Frontispiece to the Fabrica." Further information may be obtained from the Secretaria General, Instituto Arnaldo de Villanova, Duque de Medinaceli, 4, Madrid, Spain.

CORRECTION

Diagnosis of Islet-Cell Tumors of Pancreas.—The last word in the second line of the second paragraph of the abstract on diagnosis of islet-cell tumors of the pancreas, in The Journal, July 28, page 1328, should have been "hypoglycemia" rather than "hyperglycemia."

EXAMINATIONS AND LICENSURE

American Board of Anesthesiology: *Part I* Various locations, July 19 Final date for filing application is Jan. 19. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Dermatology: *Oral* St. Louis, Oct 12-15 Final date for filing applications was April 1. Sec., Dr. B. M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine *Written* Oct. 15, 1956 Final date for filing application was May 1. *Oral* New York City, Sept 21-25 Final date for filing application was May 1. Exec. Sec., Dr. William A Werrell, 1 West Main St., Madison 3, Wis.

Subspecialties Cardiovascular Disease Chicago, Nov. 30. Final date for filing application was June 1. *Gastroenterology* Philadelphia, April 5-6 Final date for filing application is March 1.

American Board of Neurological Surgery Examination given twice annually, in the spring and fall In order to be eligible a candidate must have his application filed at least six months before the examination time Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St Louis 10.

American Board of Obstretics and Gynecology *Part I* Various communities throughout the United States and Canada, Feb. 1. Candidates must submit case reports to the Office of the Secretary within 30 days of being notified of their eligibility to Part I. *Part II* Chicago, May 16-25 Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland

American Board of Ophthalmology. *Oral* St. Louis, Oct 20-24 *Written* Jan. 21. Final date for filing application was July 1. *Oral* New York, May 23-27; Chicago, Oct. 7-11. Sec., Dr Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral Part II* Chicago, January 1957. Final date for filing application was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3

American Board of Otolaryngology. *Written and Oral.* Chicago, Oct 8-11. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology. *Written for Pathological Anatomy and Clinical Pathology*, Oct. 4-6. Final date for filing application was Sept. 1. Sec., Dr. Edward B. Smith, 1040-1232 W. Michigan St, Indianapolis 7.

American Board of Pediatrics. *Oral. Part II.* New York City, Oct 12-14, and San Francisco, Dec. 7-9. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation *Parts I and II.* New York City, June 8-9. Final date for filing application is March 1. Sec., Dr. Earl C. Elkins, 200 First St, S W., Rochester, Minn

American Board of Plastic Surgery. Miami, Oct. 17-19. Corres Sec, Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8

American Board of Preventive Medicine. *Oral and Written Public Health.* Philadelphia, Nov. 8-10. Sec., Dr. Ernest L. Stebbins, 615 N Wolfe St., Baltimore, Md.

American Board of Proctology *Oral and Written* Philadelphia, Sept 29. Final date for filing application was Sept 1. Sec, Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology. *Oral* New York, Dec 10-11 and New Orleans, Mar. 18-19 Final date for filing application is Sept 10. Sec, Dr. David A. Boyd, Jr., 102-110 Second Ave, S W, Rochester, Minn.

American Board of Radiology. Los Angeles, Sept 30-Oct. 4 Final date for filing application was June 1. Tampa, April 1-6 Final date for filing application is Jan 1. Washington, Sept. 23-28 Final date for filing application was June 1. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg, Rochester, Minn.

American Board of Surgery *Part I.* Various Centers Throughout the United States and in Certain Military Centers Abroad, Oct. 31 *Part II* Buffalo, Sept. 24-25, Chicago, Oct. 15-16, New Haven, Nov 19-20, Kansas City, Kan, Dec. 10-11, Los Angeles, Jan 14-15, San Francisco, Jan 17-18, Houston, Feb 18-19, Nashville, Mar. 11-12, Boston, April 8-9, and New York, June 10-11.

American Board of Urology. February 1957. Sec., Dr. William Niles Wishard, 1711 N. Capital Ave., Indianapolis 7.

Board of Thoracic Surgery *Written* Various centers throughout the country, Sept. 7. Final date for filing applications was July 1 A subsequent written examination will be held in February 1957, and the closing date for registration is Dec. 1, 1956. Sec., Dr. William M Tuttle, 1151 Taylor Ave., Detroit 2.

DEATHS

Russell, Nelson Gorham ⊕ Buffalo; born in New Market, Ontario, Canada, Aug. 26, 1872; University of Buffalo School of Medicine, 1895; joined the faculty of his alma mater as assistant in pathology, becoming assistant in medicine, professor clinical medicine, and professor of medicine; retired in 1937, on reaching his 65th birthday, and was named professor of medicine emeritus; specialist certified by the American Board of Internal Medicine; member of the American Association of Pathologists and Bacteriologists, American Clinical and Climatological Association, American Heart Association, American Association of the History of Medicine, American Trudeau Society, Society of Experimental Biology and Medicine, and the Buffalo Academy of Medicine; fellow and ex-governor of the American College of Physicians; veteran of the Spanish-American War; cited by General Pershing for "exceptionally meritorious and conspicuous services" during World War I; formerly chairman of the advisory health board; the Chancellor's medal of the University of Buffalo was presented to him on Feb. 22, 1945; in September, 1951, the annual bishop's award of the Episcopal Diocese of Western New York was presented to him for "outstanding service to the church"; the following year, at the annual dinner of the university's alumni board, received the Samuel P. Capen award for outstanding service to the university; consultant in medicine at the J. M. Adam Memorial Hospital in Perrysburg, Buffalo Columbus Hospital, and the Edward J. Meyer Memorial Hospital, where he formerly served as chairman of the board of managers; consulting physician and honorary vice-president and member of the board of trustees at the Buffalo General Hospital; died June 4, aged 83, of coronary occlusion.

Shepherd, Clara Sargent, Middleboro, Mass.; born in Valdosta, Ga., in 1889; University of Michigan Medical School, Ann Arbor, 1915; worked in the diabetic department at the Battle Creek (Mich.) Sanitarium; in 1919 went to China as the first woman physician to serve in the field of public health; worked with the National Council on Health Education, which was jointly sponsored by the Y. M. C. A. and the Y. W. C. A., and was on the faculty of the Women's College of Physical Education in Shanghai, which later became a department of Ginling Women's College in Nanking; for 20 years served as physician and public health director in the American Board of Missions at Shaowu and Foochow in Fukien; for a brief period was school physician at the Kuling American School; was evacuated from China just previous to Pearl Harbor, became health physician for the schools of Lansing, Mich., and later served as a physician on the staff of the outpatient department of Herman Kiefer Hospital in Detroit; retired from medical practice in 1952; assisted in writing textbooks on health for Chinese government schools and, with Dr. W. W. Peter, promoted public health campaigns in China's major coastal cities; died in St. Luke's Hospital July 1, aged 67, of cancer.

Davis, George G. ⊕ Anchorage, Alaska; born in Chicago in 1879; Rush Medical College, Chicago, 1904; at one time associate professor of surgery at the University of the Philippines College of Medicine in Manila; served on the faculty of his alma mater and the University of Illinois College of Medicine in Chicago; during World War I served as honorary lieutenant colonel with the Royal Army Medical Corps and chief of staff of surgical service in the Third General Hospital in France; after the war practiced surgery in Chicago until 1943, when he went to Anchorage as chief of staff of the Alaska Railroad Hospital from 1943 to 1945; served as medical officer of the Alaska Native Service from 1945 to 1955; chief surgeon of the Carnegie-Illinois Steel Corporation in the Chicago area from 1919 to 1937; member of the House of Delegates of the American Medical Association in 1950; member of the founders group of the American Board of Surgery; member of the Western Surgical Association and the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; on the staff of the Providence Hospital in Anchorage; died April 21, aged 77, of cerebral hemorrhage.

Cooke, Jean Valjean, St. Louis; born in Brownsville, Pa., June 19, 1883; Johns Hopkins University School of Medicine, Baltimore, 1908; instructor of pathology at the University and Bellevue Hospital Medical College in New York City from 1908 to 1910; instructor in pathology at the Tulane University School of Medicine, New Orleans, 1911-1912; from 1912 to 1917 associate in pathology and director of the laboratory at the University of California School of Medicine in San Francisco; professor emeritus of pediatrics at the Washington University School of Medicine, where he joined the faculty as assistant professor of pediatrics, later became associate professor and professor; specialist certified by the American Board of Pediatrics; during World War I served as consultant on epidemic diseases to the Secretary of War; member of the American Pediatric Society, which he served as president, and the Missouri State Medical Association; on the staffs of the St. Louis Maternity, St. Louis City, and St. Louis Children's hospitals; died in the Barnes Hospital June 29, aged 73, of lymphosarcoma.

Weld, Edward Howland ⊕ Rockford, Ill.; born in Stillman Valley March 5, 1881; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1907; entered the Mayo Foundation in Rochester, Minn., in February, 1916, and left June 1, 1919; member of the House of Delegates of the American Medical Association 1947, 1948, and 1949; for 12 years councilor of the first district of the Illinois State Medical Society, which he later served as president; past-president and vice-president of the Winnebago County Medical Society; charter member of the American Geriatric Society; member of the American Urological Society and the Industrial Medical Association; on the staffs of the Rockford Memorial and St. Anthony hospitals; died in Mayo Clinic, Rochester, Minn., July 6, aged 75, of leukemia.

Greenman, Lawrence ⊕ Pittsburgh; born in Brooklyn, N. Y., March 23, 1921; Yale University School of Medicine, New Haven, Conn., 1944; Renziehausen assistant professor of research medicine at the University of Pittsburgh School of Medicine; at one time on the faculty of his alma mater and Washington University School of Medicine in St. Louis; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; interned at the Grace-New Haven Community Hospital in New Haven, Conn.; served a residency at the Barnes Hospital in St. Louis, Grace-New Haven Community Hospital in New Haven, Conn., and the Presbyterian Hospital; on the staffs of the Children's Hospital, Presbyterian Hospital, and Woman's Hospital; died June 20, aged 35, of brain tumor.

Guedel, Arthur Ernest, Los Angeles; born in Cambridge City, Ind., June 13, 1883; Indiana University School of Medicine, Indianapolis, 1908; emeritus associate clinical professor of surgery (anesthesiology) at the University of Southern California

---

⊕ Indicates Member of the American Medical Association.

School of Medicine; specialist certified by the American Board of Anesthesiology; member of the American Society of Anesthesiologists; veteran of World War I; from 1920 to 1928 lecturer on anesthesiology at his alma mater; for many years on the staffs of the Indianapolis General, St. Vincent's, and Protestant Deaconess hospitals in Indianapolis; served on the staffs of the Cedars of Lebanon, Queen of Angels, and California hospitals, and the Methodist Hospital of Southern California; died June 10, aged 72, of arteriosclerotic heart disease.

Wear, Thomas Ralph ⊕ Tuscaloosa, Ala.; born in Haleyville, Feb. 23, 1917; Washington University School of Medicine, St. Louis, 1942; interned at the Employees' Hospital of the Tennessee Coal, Iron and Railroad Company in Fairfield, Ala.; formerly a resident at the Regional Hospital (U. S. Army) Aviation Cadet Center, San Antonio, Texas; veteran of World War II; practiced in Hamilton, where he was vice-president of the Marion County Medical Society, trustee of the local school board, and county health officer; on the staff of the Bryce Hospital; member of the American Academy of General Practice; died in the Wilson Hospital in Haleyville June 23, aged 39, of lymphocytic leukemia.

Capell, Clarence Swift ⊕ Kansas City, Mo.; born in Marietta, Ohio, Nov. 14, 1874; John A. Creighton Medical College, Omaha, 1902; specialist certified by the American Board of Urology; member of the American Urological Association and the Kansas City Southwest Clinical Society; past-president of the Jackson County Medical Society; president of the Kansas City Urological Society, 1951-1955; veteran of World War I; served as chief and president of the staff, St. Mary's and St. Joseph hospitals; for many years director and chief of the urologic service, Kansas City General Hospital; died June 24, aged 81, of coronary arteriosclerosis.

Hammond, Robert Bertine, Bradenton, Fla.; born in Amenia, N. Y., Feb. 3, 1883; Long Island College Hospital, Brooklyn, N. Y., 1908; member of the Medical Society of the State of New York and the American Society of Anesthesiologists; fellow of the American College of Anesthesiology, of which he was a founder; past-president of the American Regional Society of Anesthesiologists, New York Society of Anesthetists, and the Eastern Society of Anesthesiologists; an associate member of the American Medical Association; specialist certified by the American Board of Anesthesiology; for many years practiced in White Plains, N. Y.; served on the staffs of the Grasslands Hospital in Valhalla, N. Y., the St. Agnes Hospital in White Plains, N. Y., and the White Plains (N. Y.) Hospital, where he died May 31, aged 73, of arteriosclerosis.

Neilson, John Land ⊕ Captain, U. S. Navy, retired, Washington, D. C.; born July 31, 1880, Harvard Medical School, Boston, 1902; appointed assistant surgeon in the Navy in 1902; during his career of 43 years, served as commanding officer of naval hospitals in Guam, San Diego, Pearl Harbor, and Mare Island; served in the Philippines and Guam, at the Naval Training Station at Newport, R. I., at Mare Island, and aboard the USS Buffalo; served in the office of the Navy surgeon general, as flag surgeon of the U. S. Pacific Fleet, Destroyer Force, and aboard the USS California, and as a member of the Navy Retirement Board in Washington; retired Jan. 1, 1943; fellow of the American College of Surgeons; died June 14, aged 75, of myocardial infarction.

Kaufman, Charles J. ⊕ Castle Point, N. Y.; born in Brooklyn, N. Y., Jan. 29, 1897; Cornell University Medical College, New York City, 1921; served on the faculty of his alma mater; formerly associate professor of medicine (tuberculosis) at the University of Colorado School of Medicine in Denver; member of the American College of Chest Physicians and the American Trudeau Society; at one time medical director of the National Jewish Hospital in Denver and on the staffs of the Sea View Hospital in Staten Island and the Metropolitan Hospital in New York City; chief, tuberculosis service, Veterans Administration Hospital; died in the Presbyterian Hospital, New York City, June 15, aged 59, following a prostatectomy.

Singer, Karl ⊕ Chicago; Medizinische Fakultät der Universität, Vienna, Austria, 1927; specialist certified by the American Board of Internal Medicine; member of the Association of American Physicians; fellow of the American College of Physicians; at one time associate in physiology at his alma mater; served on the faculty of Tufts College Medical School in Boston, where he was a research fellow at the Beth Israel and Joseph H. Pratt Diagnostic hospitals; since 1947 director of the hematology department at the Michael Reese Hospital, where he died July 12, aged 54, of bronchopneumonia and carcinoma of the lung.

Abner, John W., Atchison, Kan.; Eclectic Medical University, Kansas City, Mo., 1914; died June 8, aged 88, of chronic aortitis.

Amos, William Frederick, Portland, Ore.; Willamette University Medical Department, Salem, 1890; Columbia University College of Physicians and Surgeons, New York City, 1892; at one time on the faculty of the University of Oregon Medical School; served as secretary of the Oregon State Medical Society; at one time an associate editor of Medical Sentinel; died June 25, aged 86.

Anderson, Raymond Ravenel, Jersey City, N. J.; Howard University College of Medicine, Washington, D. C., 1930, died in the Jersey City Medical Center June 22, aged 54.

Anderson, Richard Speight ⊕ Whitakers, N. C.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1924; veteran of World War II; for many years on the staff of the Rocky Mount (N. C.) Sanitarium; died in the Edgecombe General Hospital, Tarboro, June 6, aged 57.

Anrode, Ralph Austen ⊕ Davenport, Iowa; Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn, Prussia, Germany, 1920; on the staffs of the Mercy Hospital and the St. Luke's Hospital, where he died June 29, aged 65, of coronary occlusion.

Armstrong, Frederic Clinton ⊕ Cascade, Iowa; John A. Creighton Medical College, Omaha, 1920; member of the American Academy of General Practice; veteran of World War I; died in the Veterans Administration Hospital, Iowa City, June 30, aged 61, of carcinoma of the lung with metastasis to the kidney.

Avery, Hiram Henry, Omaha; Kansas City (Mo.) Hahnemann Medical College, 1914; veteran of World Wars I and II; died in the Veterans Administration Hospital May 17, aged 65, of ruptured aortic aneurysm.

Bailey, Thomas B., Marshall, Texas; Baylor University College of Medicine, Dallas, 1916; died in the Kahn Memorial Hospital June 22, aged 71.

Bang, Sarah Allen, Havertown, Pa.; Temple University School of Medicine, Philadelphia, 1906; died in the Doctors Hospital, Philadelphia, June 15, aged 86, of ovarian tumor.

Barber, Edna Mabel, Alameda, Calif.; Oakland (Calif.) College of Medicine and Surgery, 1914; an associate member of the American Medical Association; died June 20, aged 71, of melanotic carcinoma with metastases.

Barber, William Jefferson ⊕ Butler, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1929; member of the American Academy of General Practice; medical superintendent and owner of the Barber Hospital; died in the Jefferson-Hillman University Hospital, Birmingham, June 11, aged 49, of obstructive jaundice and pancreatitis.

Barnes, Robert Wallace, Dallas, Texas (licensed in Texas under the Act of 1907); died June 19, aged 87.

Barnett, Thomas Rowland ⊕ Hillsboro, Texas; Baylor University College of Medicine, Dallas, 1926; member of the American Academy of General Practice; part owner of the Hillsboro Clinic-Hospital, where he was director of the staff, and where he died June 21, aged 57, of coronary occlusion.

Beare, John William ⊕ Chester, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1907; member of the board of health of Chester; on the staffs of St. Clement's Hospital in Red Bud and St. Andrew's Hospital in Murphysboro; died June 23, aged 75, of arteriosclerotic heart disease with coronary thrombosis.

Berke, Samuel David ⊕ Indio, Calif.; Dalhousie University Faculty of Medicine, Halifax, Nova Scotia, Canada, 1926; veteran of World War II; on the staffs of the Casita and Coachella Valley hospitals; died in the Veterans Administration Hospital, Los Angeles, June 5, aged 52, of bronchiectasis and cor pulmonale.

Berry, Joseph Alonzo ⊕ Tuskegee, Ala.; Rush Medical College, Chicago, 1925; fellow of the International College of Surgeons; member of the American Society for Surgery of the Hand; on the staff of the Veterans Administration Hospital; died in New York City June 13, aged 60, of aortic aneurysm.

Bilstad, Gunerius Ellsworth, Cambridge, Wis.; Northwestern University Medical School, Chicago, 1898; died June 26, aged 82, of arteriosclerotic heart disease.

Binder, Israel ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1911; member of the American Academy of Pediatrics; on the staff of the St. Luke's and Children's Medical Center and the Olney Hospital and Lawncrest Diagnostic Clinic; died in Panama City, Fla., June 11, aged 65.

Blackburn, Cecil Howell ⊕ Conyers, Ga.: Washington University School of Medicine, St. Louis, 1941; member of the Medical Association of the State of Alabama: died June 4, aged 46.

Bostick, John Benton ⊕ Lieut. Commander, U. S. Navy, retired, Fresno, Calif.: College of Physicians and Surgeons of San Francisco, 1913; entered the U. S. Navy July 20, 1921; retired Sept. 1, 1939: veteran of the Spanish-American and World Wars; died June 6, aged 80, of cerebral vascular thrombosis.

Boswell, Harry Dillman ⊕ Henryetta, Okla.: Northwestern University Medical School, Chicago, 1912, died in the Haynes Hospital July 4, aged 73, of pneumonia and heart disease.

Breitenbach, Lawrence Prell, Detroit; Detroit College of Medicine, 1911; formerly on the faculty of his alma mater; served on the staff of St. Mary's Hospital; died June 12, aged 74, of arteriosclerosis.

Briggs, George Abiel ⊕ Sacramento, Calif.; Medical Department of the University of California, San Francisco, 1905; served overseas during World War I; past-president of the Sacramento Society for Medical Improvement; fellow of the American College of Surgeons; one of the founders, member of senior staff, and for many years secretary-treasurer of the board of trustees of the Sutter General Hospital, where he died June 10, aged 75, of carcinoma of the prostate with metastases.

Brown, John Charles, New York City; Albany (N. Y.) Medical College, 1892; died in St. Luke's Hospital June 14, aged 85, of pneumonia.

Bryan, William Juel, Jr. ⊕ Tulsa, Okla.; Baylor University College of Medicine, Dallas, Texas, 1921; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Diabetes Association; on the visiting staff of the St. John's Hospital; on the staff of the Hillcrest Medical Center, where he served on the governing board and later was named honorary board member; died July 4, aged 60, of cancer.

Bryant, Arthur Ralph, Beatrice, Neb.; Rush Medical College, Chicago, 1930; an associate member of the American Medical Association; past-president of the Gage County Medical Society; veteran of World War II; on the staffs of the Mennonite Deaconess Home and Hospital and the Lutheran Hospital, where he died June 15, aged 52, of pinealoma.

Budaeff, Ivan Titus ⊕ Daly City, Calif.; University of Oregon Medical School, Portland, 1930; member of the American Academy of General Practice; died June 12, aged 60, of carcinoma of the lung with metastasis.

Bussey, Benjamin Peyton, Cairo, Ga.; Medical College of Georgia, Augusta, 1954; interned at the Charity Hospital of Louisiana in New Orleans, where he served a residency; killed June 29, aged 28, in a plane crash.

Butler, Henry Anderson ⊕ Liberty, Miss.; University of Tennessee College of Medicine, Memphis, 1934; died July 4, aged 57, of heart disease.

Byrd, Emmett Earl ⊕ Jonesboro, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1912; veteran of World War II; served as director of the Washington County Health Department; retired from the Veterans Administration May 31, 1950; died in the Memorial Hospital, Johnson City, April 23, aged 65, of coronary disease.

Campbell, Clarence G., New York City: Bellevue Hospital Medical College, New York City, 1890; died June 16, aged 88, of bronchopneumonia, arteriosclerotic heart disease, and generalized arteriosclerosis.

Clarke, James Cunningham ⊕ La Grange. Ill.: Rush Medical College, Chicago, 1913: fellow of the American College of Surgeons: on the staffs of the Community Memorial General Hospital and the Hinsdale (Ill.) Sanitarium and Hospital, where he died July 12, aged 70, of a heart attack.

Cooper, Jesse Robert ⊕ New Castle, Pa.: Western Pennsylvania Medical College, Pittsburgh, 1894; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, Radiological Society of North America, and the American College of Radiology: veteran of World War I; on the staff of the New Castle Hospital; died in the Jameson Memorial Hospital June 14, aged 84, of cerebral hemorrhage.

Darrah, John Russell ⊕ Colonel, U. S. Army, retired, Amarillo, Texas; University of Nebraska College of Medicine, Omaha, 1935; certified by the National Board of Medical Examiners; veteran of World War II; retired from the regular Army June 18, 1955; died June 6, aged 48.

Douglass, Henry Francis, Washington, D. C.; Howard University College of Medicine, Washington, D. C., 1938; interned at the Freedmen's Hospital, where he served a residency; died suddenly June 7, aged 42, of a heart attack.

Engel, Henry ⊕ Dover, Ohio; Ludwig-Maximilians-Universität Medizinische Fakultät, Munchen, Bavaria, Germany, 1907: died in the Mercy Hospital, Canton, June 5, aged 74, of infection following prostatic operation.

Farley, William Chase ⊕ Methuen, Mass.; Medical School of Maine, Portland, 1893; Hahnemann Medical College and Hospital of Philadelphia, 1894; on the courtesy staff of the Lawrence (Mass.) General Hospital; died June 14, aged 86, of intestinal and gastric carcinoma.

Freedman, Theodore Raphael, Far Rockaway, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York City, 1929; member of the Medical Society of the State of New York; died in St. Joseph's Hospital, New York City, June 18, aged 52, of pulmonary embolism and infarction, myocardial infarction, and coronary sclerosis.

French, William Oscar ⊕ Honolulu, Hawaii; Stanford University School of Medicine, San Francisco, 1926; served in France during World War I; in 1924-1925 was in the U. S. Army Reserve, from 1926 to 1928 in the regular Army, and from 1928 to 1932 in the National Guard; died April 11, aged 60.

Frey, Joseph Louis Edward ⊕ New York City; Georgetown University School of Medicine, Washington, D. C., 1907; died July 6, aged 71, of general and coronary arteriosclerosis.

Hankey, Stacy Marlin ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1903; specialist certified by the American Board of Urology; member of the American Urological Association; on the staffs of the Veterans Administration Hospital and the Passavant Hospital, where he died June 21, aged 82, of carcinoma of the stomach.

Hester, William Lee ⊕ Lubbock, Texas; Southern Methodist University Medical Department, Dallas, 1914; associated with the Regional Veterans Administration; died in St. Mary of the Plains Hospital in Lubbock May 30, aged 65, of bronchogenic carcinoma with cerebral metastasis.

Heyman, Ernest Fred ⊕ Red Bank, N. J.; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1923; died in the Monmouth Memorial Hospital, Long Branch, May 7, aged 55, of carcinoma of the prostate.

Hildebrand, William Owen ⊕ Topeka, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1905; died in the Elkhart (Ind.) General Hospital June 1, aged 80, of acute coronary occlusion.

Jenkins, Bertha Elizabeth, Oakland, Calif.; Oakland College of Medicine and Surgery, 1919; an associate member of the American Medical Association; died May 22, aged 70.

Kirkland, Benjamin Franklin, Long Beach, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; formerly member of the city council; died May 24, aged 86.

Komisar, Paul Stanislaw ⊕ Erie, Pa.; Tufts College Medical School, Boston, 1928; member of the American Academy of General Practice; served during World War II; on the staffs of the Hamot Hospital, where he interned, and St. Vincent's Hospital; died May 29, aged 57, of coronary thrombosis.

LeComte, John Radway, Albuquerque, N. M.; Columbia University College of Physicians and Surgeons, New York City, 1903; veteran of World War I; died in the Veterans Administration Hospital May 15, aged 76, of heart disease.

Laing, Stanley Glen ⊕ Kansas City, Kan.; St. Louis University School of Medicine, 1940; on the staffs of St. Margaret's Hospital, where he interned, and Providence and Bethany hospitals; died in Lakeview, Ark., May 26, aged 55, of acute coronary occlusion.

Lane, Louis Perpignan, Jr. ⊕ Brooklyn, N. Y.; Long Island College Hospital, Brooklyn, 1913; served during World War I; on the staffs of Coney Island, Victory Memorial, and Harbor hospitals; died May 30, aged 68, of arteriosclerotic heart disease.

Levi, Albert Abraham ⊕ Minneapolis; Julius-Maximilians Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1908; member of the Illinois State Medical Society; died in Mount Sinai Hospital May 3, aged 72, of coronary thrombosis and hemiplegia.

Lhevine, Morris Boise, Tulsa, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1917; an associate member of the American Medical Association; member of the Radiological Society of North America and the American College of Radiology; specialist certified by the American Board of Radiology; for many years secretary of the board of directors of the Hillcrest Medical Center, where he was director of radiology and where he died May 19, aged 70, of arteriosclerotic heart disease.

Lofton, Frederick A. ⊕ Chicago; Harvey Medical College, Chicago, 1901; served on the staff of St. Bernard's Hospital, where he died June 9, aged 82, of arteriosclerosis.

Lynch, William Joseph ⊕ Weimar, Calif.; National University of Ireland, 1919; member of the American Trudeau Society; for many years on the staff of the Weimar Joint Sanatorium, where he died May 21, aged 58.

McCarthy, Patrick Henry, Cambridge, Mass. (licensed in Massachusetts in 1900); died in Arlington May 15, aged 82, of cerebral vascular accident.

McCarty, James Joseph, Jr., Chicago; Harvard Medical School, Boston, 1910; died May 28, aged 71.

McClellan, Ernest Edward ⊕ Huntington, W. Va.; Medical College of Virginia, Richmond, 1933; on the staff of the Memorial Hospital; died July 4, aged 49, of a heart attack.

McCloskey, Edward William, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1911; an associate member of the American Medical Association; fellow of the American College of Physicians; veteran of World War I; served on the staff of the Chestnut Hill Hospital; died in the Lankenau Hospital June 16, aged 71, of myasthenia gravis.

McDowell, Charles Albert ⊕ Covina, Calif.; University of Pittsburgh School of Medicine, 1925; died May 14, aged 55.

McNamara, John Francis, Chicago; Loyola University School of Medicine, Chicago, 1921; served as senior surgeon at the Mercy Hospital; died May 29, aged 67, of bronchopneumonia.

Magill, H. Kelvin ⊕ Lexington, Mass.; University of Colorado School of Medicine, Denver, 1937; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served on the staffs of the Sancta Maria and Cambridge City hospitals in Cambridge, Boston City Hospital, Winchester (Mass.) Hospital, and the Brooks Hospital in Brookline; died in the Massachusetts General Hospital, Boston, May 14, aged 46, of coronary thrombosis.

Mahoney, Roy Bernard ⊕ Chicopee Falls, Mass.; Georgetown University School of Medicine, Washington, D. C., 1925; veteran of World War I; school physician; physician for the Fisk division of the U. S. Rubber Company; on the surgical staff of the Mercy Hospital in Springfield; died May 26, aged 59, of diabetes mellitus.

Main, George Chrysup, Denver; St. Louis University School of Medicine, 1924; veteran of World War I; on the staffs of the St. Anthony and Presbyterian hospitals; died May 18, aged 58, of coronary occlusion and paralysis agitans.

Martin, Mary K., Los Angeles; Hering Medical College, Chicago, 1894; died in Verdugo City, Calif., April 16, aged 87, of virus pneumonia.

Mawhinney, Harvey Norton ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1920; specialist certified by the American Board of Radiology; member of the Radiological Society of North America, fellow of the American College of Radiology; past-president of the Pennsylvania Radiological Society and the Pittsburgh Roentgen Society; on the staffs of the Sewickley (Pa.) Valley Hospital, Suburban General Hospital in Bellevue, and the Homestead (Pa.) Hospital, where he died June 17, aged 63, of injuries sustained in an automobile accident.

Meeks, John Alexander, Kite, Ga.; Hospital Medical College, Eclectic, Atlanta, 1911; died May 5, aged 73, of myocardial infarction.

Minshull, Harold Frederick, New Lexington, Ohio; Eclectic Medical College, Cincinnati, 1918; member of the Ohio State Medical Association; secretary of the Perry County Medical Society; county coroner; health commissioner of Perry and Morgan counties; on the staffs of the Bethesda and Good Samaritan hospitals in Zanesville; died May 21, aged 59, of coronary occlusion.

Mitchell, Edward Francis ⊕ Clinton, Mass.; Harvard Medical School, Boston, 1922; served on the staff of the Clinton Hospital; died May 23, aged 70, of coronary thrombosis.

Mitchener, William Claude, Okmulgee, Okla.; Memphis (Tenn.) Hospital Medical College, 1902; an associate member of the American Medical Association; served as mayor; formerly on the board of the Okmulgee City Hospital; died in Oklahoma City May 24, aged 80, of myocardial degeneration, bronchopneumonia, and uremia.

Monteverde, Whitten Cantwell ⊕ Brentwood, Calif.; St. Louis University School of Medicine, 1929; formerly practiced in Pittsburg, where he was a member of the city council; on the staff of the Pittsburg Community Hospital; died May 23, aged 53, of coronary thrombosis.

Moon, James P. ⊕ Winchester, Tenn.; University of Nashville Medical Department, 1908; past-president of the Williamson County Medical Association; director of the Coffee and Franklin County Health Departments; served on the staff of the Mid-State Baptist Hospital, Nashville, where he died May 28, aged 74, of uremia.

Morden, Lucetta, Brooklyn, N. Y.; Trinity Medical College, Toronto, Canada, 1904; died in the Greenpoint Hospital June 2, aged 75, of heart disease, bronchopneumonia, and cancer of the gastrointestinal tract.

Munson, Henry Orson ✠ Rushville, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1890; on the staff of the Phelps Hospital in Macomb; died in Jacksonville July 14, aged 88, of coronary thrombosis.

Murphy, Edward John, Rochester, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1904; during World War II was associated with the U. S. Public Health Service, assigned to the Bureau of Printing and Engraving, Washington, D. C.; served on the staffs of the Rockaway Beach (N. Y.) Hospital, St. Joseph Hospital in Far Rockaway, and St. Mary's Hospital in Brooklyn; died in the Genesee Hospital May 24, aged 76, of carcinoma of the stomach.

Newsome, Levi J., Topeka, Kan.; Meharry Medical College, Nashville, Tenn., 1907; died in the Stormont-Vail Hospitals June 23, aged 82, of cirrhosis of the liver.

Newton, Herman Christian ✠ Chicago; Northwestern University Medical School, Chicago, 1905; also a graduate in dentistry; died in the Wesley Memorial Hospital July 1, aged 80, of a heart attack.

Nihart, Orrin H., Edon, Ohio; Starling Medical College, Columbus, 1898; served as coroner and as state legislator; affiliated with the Cameron Hospitals, Bryan; died in the Mound Park Hospital, St. Petersburg, Fla., May 29, aged 84, of ruptured aneurysm of the abdominal aorta and general arteriosclerosis.

Niven, Joseph Dougal, Tucker, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; University of Nashville (Tenn.) Medical Department, 1894; died in Little Rock May 17, aged 88, of carcinoma of the kidney.

Obers, Samuel Joseph ✠ New York City; New York University College of Medicine, New York City, 1937; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; served on the staffs of the Stony Lodge Sanitarium in Ossining, and the Beth Israel and Lenox Hill hospitals; died May 12, aged 42.

Peterson, Ralph Otto ✠ Racine, Wis.; Marquette University School of Medicine, Milwaukee, 1916; fellow of the American College of Surgeons; on the staff of St. Mary's Hospital; died June 6, aged 68, of cerebral hemorrhage.

Rowley, Antinous Gilbert, Middleton, Wis.; Rush Medical College, Chicago, 1899; served as health officer; died May 24, aged 81, of carcinoma of the prostate and essential hypertension.

Runkle, George Darius ✠ Stockton, Ill.; Northwestern University Medical School, Chicago, 1903; died July 3, aged 77, of abdominal carcinoma.

Sawyer, Dwight M. ⊙ Glens Falls, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1911; past-president and secretary of the Warren County Medical Society; member of the Glens Falls Academy of Medicine; consulting physician for the Glens Falls Hospital, where he was past-president, vice-president, and secretary of the staff; an examining physician for the draft board during World Wars I and II; died May 7, aged 73, of aneurysm of the aorta.

Schrader, Merlin Arthur, Melbourne, Iowa; State University of Iowa College of Medicine, Iowa City, 1940; member of the American Society of Anesthesiologists; died in the Skiff Memorial Hospital, Newton, July 2, aged 42, of injuries received in an automobile accident.

Silliman, George Stephen ✠ Roanoke, Va.; Albany (N. Y.) Medical College, 1908; associated with the Veterans Administration; died in the Veterans Administration Hospital April 19, aged 73, of coronary thrombosis.

Smith, Alfred Nelson ✠ Glasgow, Mont.; Northwestern University Medical School, Chicago, 1911; on the staff of the Frances Mahon Deaconess Hospital; died in Havre June 22, aged 73, of peritonitis, following a ruptured diverticulum.

Smith, Nina Ream, Monterey Park, Calif.; Sioux City (Iowa) College of Medicine, 1900; an associate member of the American Medical Association; died in the Collis P. and Howard Huntington Memorial Hospital, Pasadena, June 2, aged 88, of coronary thrombosis.

Steinfeld, Julius ✠ Des Plaines, Ill.; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1920; member of the American Psychoanalytic Association and the American Psychiatric Association; medical director and owner of the Forest Sanitarium; died in Zurich, Switzerland, June 27, aged 60, of coronary occlusion.

Sturm, Ellis A., Atlanta, Ga.; Eclectic Medical Institute, Cincinnati, 1895; died April 30, aged 87, of arteriosclerosis and uremia.

Thewlis, Malford Wilcox ✠ Wakefield, R. I.; Medical School of Maine, Portland, 1911; founder and secretary of the American Geriatrics Society; author of "The Care of the Aged (Geriatrics)"; served as associate editor of *Medical Times;* on the staff of the South County Hospital, where he died June 3, aged 66.

Waugh, Fred Duvall, Riverside, Ill.; Northwestern University Medical School, Chicago, 1908; died in the Research and Educational Hospitals in Chicago March 4, aged 86.

Wells, George Marion ✠ Bowling Green, Ky.; Loyola University School of Medicine, Chicago, 1916; veteran of World Wars I and II; since 1931 director of the Warren County Health Department; from 1952 to 1956 medical advisor at the Western Kentucky State Teachers College; for many years practiced in Lafayette, Ind.; died recently, aged 68, of coronary thrombosis.

Whitledge, Herbert Edwin, Evansville, Ind.; University of Louisville (Ky.) Medical Department, 1897; veteran of World War I; served in the U. S. Public Health Service Reserve and the Veterans Bureau; at one time associated with the Veterans hospitals in Camp Kearney, Calif., and Outwood, Ky.; died in St. Mary's Hospital May 5, aged 81.

Williams, Arthur Grady ✠ Florala, Ala.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1913; vice-president of the Bank of Florala; died May 16, aged 68, of coronary disease.

Wilson, Cas Pharaoh ✠ Sevierville, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1917; founder and medical director of the Wilson Hospital; died in the Fort Sanders Presbyterian Hospital, Knoxville, May 29, aged 64.

York, Marion Nicholas, Hawthorne, Calif.; University of Arkansas School of Medicine, Little Rock, 1920; died April 12, aged 63.

Young, Glyndon Angus, Minden, Nev.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1900; formerly practiced in Ponca, Neb., where he served as mayor and county health officer; served overseas during World War I; died June 28, aged 80, of carcinoma of the prostate.

Young, Lawrence Randolph, Mandeville, La.; Kentucky School of Medicine, Louisville, 1906; died June 18, aged 73.

Zaborowski, Francis Leo ✠ Philadelphia; Temple University School of Medicine, Philadelphia, 1926; fellow of the American College of Surgeons; an instructor in surgery at his alma mater; on the staffs of the Northeastern and Temple University hospitals; died in Fort Washington, Pa., June 6, aged 55.

Zawislak, Joseph John ✠ Lawrence, Mass.; Middlesex College of Medicine and Surgery, Waltham, 1936; served overseas during World War II; formerly physician for the social disease clinic of the Municipal Health Department; school physician; on the staffs of the Lawrence (Mass.) General Hospital and the Bon Secours Hospital in Methuen; died May 10, aged 47, of coronary thrombosis.

Zenner, Philip ✠ Cincinnati; Miami Medical College, Cincinnati, 1875; professor emeritus of neurology at the University of Cincinnati College of Medicine; member of the American Neurological Association; oldest retired staff member of the Jewish Hospital; died June 25, aged 104.

FOREIGN LETTERS

AUSTRIA

Meeting of Gynecologists.—The fourth Congress of Austrian Gynecologists met in Bad Ischl in June.

Uterine Prolapse.—Dr. T. Antoine of Vienna stated that in uterine prolapse operation should be performed, provided there are no general contraindications. Treatment with a pessary may be considered only in exceptional cases. The operative methods vary greatly and the choice depends on the preference of the operator, the degree of the prolapse, the patient's marital status, and the presence or absence of urinary incontinence. The simplest operation is colporrhaphy, by which satisfactory results are obtained in patients with moderate prolapse, when the operation is combined with restoration of the position of the bladder and the construction of a high perineum. Interposition is still an effective method in women of advanced age with large cystoceles. Its use is now greatly reduced by the Manchester operation, which also yields excellent results. Lifting up or fixation of the cervix may be obtained also by other operations such as Kjelland's or by shortening or fixation of the sacro-uterine ligaments at the cervix. Hysterectomy should be performed only exceptionally in patients with a normal uterus. Halban's operation, which consists of amputation of the cervix and obliteration of the vesico-uterine excavation with subsequent colporrhaphy, proved to be valuable in patients with lesser degrees of prolapse. In women of advanced age, one may perform a vaginal obliteration, with or without obliteration of the vulva, or simple obliteration of the vulva. The Spalding-Richardson operation consists of amputation of the body of the uterus and of the cervix, and in this operation only the supravaginal portion of the cervix is spared. It is supposed to provide better support to the vagina by preserving the cardinal ligaments. Other recent techniques include the cutaneous transplantation (Ruiz-Arce), the interposition-like technique (Thiessen), the insertion of tongues of cartilage into the interior vaginal wall (Gallo), and the sagittal gathering up of the vagina (Lorbeer). Only in rare cases is it necessary to perform a laparotomy in the course of operation for prolapse.

Vaginal Operation for Prolapse.—O. Kiser of St. Gallen reported a series of 872 vaginal operations for prolapse and 3 exohysteropexies. Ten patients with prolapse and severe general disease were treated with the aid of a pessary. Twenty per cent of the women operated on were over 60 years of age, the oldest being 90. In 63% an anterior and posterior plastic operation was performed, and in most of these the cervix was amputated and the cardinal ligaments were gathered up. In 37% the uterus was extirpated by the vaginal route, either because of climacteric hemorrhages or fibromyoma or because of extensive or total prolapse in patients of advanced age. In nearly 33% various additional operations were performed. No operative deaths (for up to 30 postoperative days) occurred. The most important postoperative complications were pyuria (20%), a febrile course (12%), thromboses (2.5%), and embolism (1.3%). The number of thromboembolisms was markedly reduced by systematic physical and chemical prophylaxis, but the incidence of hemorrhages (4.4%) was increased. Follow-up observations of 64% of the patients were made, and recurrences were observed in 12 patients (in 3 of them after additional deliveries). Incontinence of urine had been present in more than 50% of the patients; in 90% of these a complete recovery resulted from the operation, 7.5% were improved, and 1.8% were therapeutic failures.

Uterine Prolapse in Women of Advanced Age.—S. Kolonja of Klagenfurt reported on an operative technique that consists of anterior colporrhaphy, extensive colpoperineal repair, and obliteration of the vulva with construction of a high muscular perineum that extends to the opening of the urethra. A fourfold supportive effect is thus obtained. The last act of the obliterating operation, the establishment of a muscular plate that is able to provide support and which is obtained with the aid of the levator ani, the bulbocavernous muscles, and deep and superficial perineal muscles, is essential for a lasting good result. Ninety-eight women were operated on by this method, and, of these, 80 had had total prolapse and 18 partial prolapse. The age of the patients ranged from 55 to 83 years. All the patients obtained a satisfactory plastic result and were free of symptoms when they were discharged. There were no postoperative deaths. There were no recurrences in the 91 patients who could be followed up. Because the anatomic and functional results were highly satisfactory in all patients, the speaker felt justified in recommending this technique.

Pain-Relieving Operations.—Dr. Kruger of Bad Ischl stated that operations for relief of pain should primarily be limited to thoracic or, even better, perhaps, to cervical chordotomy. The pain with which the gynecologist has to deal is primarily caused by irritation of the lumbosacral plexus and the cervical plexus. Complete relief of pain may be obtained with chordotomy in the form of sectioning the spinothalamic tract. With correct technique, impairment of the pyramidal tracts and of the anterior spinal artery can be prevented. The results with high cervical chordotomy are generally excellent. A presumptive survival time of about three months must be required for considering this operation as indicated. The speaker advises against prefrontal leukotomy for relief of pain, because of the great psychic changes associated with its use and because the patients with pain are not as a rule mental patients. In patients who are expected to die within a few months, morphine is still the drug of choice.

Puerperal Mastitis.—P. Elsner and W. Thewanger, of Vienna, believe that the increased incidence of mastitis is related to the increasing and often ill-advised use of chemotherapeutic agents and particularly of antibiotics. Certain criteria, such as comparison of the total duration of the preoperative and that of the postoperative course and the rate of recurrences, suggest that treatment by conservative means (application of heat and withdrawal of milk by a breast pump) is to be preferred to the additional use of chemotherapeutic agents. These observations are supported by determinations of bacterial resistance and culture studies. In 93% of the patients Micrococcus pyogenes var. aureus was found to be the pathogen, and in 84% it was resistant to penicillin.

Metrorrhagia.—H. Zacherl of Vienna said the observation that the first hemorrhage associated with placenta previa is almost never fatal and that the same applies to subsequent hemorrhages, provided the hemoglobin level is normal, seems to suggest expectant treatment for patients in whom pregnancy has not yet progressed to full term. This procedure, however, depends on the existence of a well-organized blood bank and complete preparedness for surgical treatment. Thus, the high mortality rate among immature infants when the mother has placenta previa can be greatly reduced without endangering the life of the mother. Acquired hemorrhagic diathesis may be associated with certain complications such as ablatio placentae, severe toxicosis, missed labor, extensive Rh immunization, and amniotic fluid embolism. Such hemorrhages, which may be uncontrollable, depend on a fibrinogen deficiency, which is a rare occurrence. The mechanism of their production warrants the conclusion that a too active obstetric management may favor such hemorrhagic diathesis, and it should therefore be avoided.

Retention of the Placenta.—E. Leinzinger of Graz stated that, by filling the placenta through the umbilical vein with 70% iodopyracet injection, it has been possible for the first time to elucidate roentgenologically the causes of the placental retention in situ. In addition to abnormal structure and abnormal insertion of the placenta, mechanical impediments may also be responsible for

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

the retention of the partially detached placenta or for the incarceration of the detached placenta. Retention of the placenta is rare if methylergonovine tartrate is used as soon as the indications are clear. In one patient expression of the placenta was not performed at the optimal time, and incarceration of the placenta, recognizable in the roentgenogram, resulted.

Diabetes and Pregnancy.—G. Mestwerdt of Halle stated that the fertility of diabetic women can now be greatly increased (from 2 to 28%) and the mortality of mothers and infants could be decreased from 50 to about 1%. Early diagnosis and differentiation of pancreatic diabetes and hypophyseal diabetes are essential. It is difficult to influence the course of the latter form, which is responsible for infant death rates up to 50%. Since glycosuria is observed frequently in pregnant women, the diagnosis may be established only by an increased blood sugar level. Latent diabetes may frequently become manifest for the first time in pregnancy. A history of preceding stillbirth, malformations, and gigantic infants presents certain indications. Toxicosis is a frequent complication (30% more frequent when associated with diabetes). The incidence of malformed infants is about 10%. Pregnancy makes every patient with diabetes worse by disturbing the hypophyseal regulatory mechanism. While some stabilization may occur in the middle of the gestational period, the onset and the end of pregnancy are associated with great lability of the blood sugar level. Metabolic relationships between mother and fetus increase this lability. There is a changed responsiveness to insulin that frequently results in hyperglycemia. The hyperglycemic blood of the mother stimulates formation of insulin in the fetus. This does not pass the placenta but exerts an increased absorption effect on the sugar by a reduction of the fetal sugar in the blood. With too large a dose of insulin, hypoglycemia results in mother and infant, and the fetus may die. Strict and constant control is, therefore, essential. In the infants, control of the blood sugar level is of less importance, since it is highly labile even under normal conditions. Administration of glucose by mouth is indicated. Increase in weight occurs slowly in most patients because of the slow reduction of the edema. Birth trauma occurs frequently, and, therefore, cesarean section seems to be the best form of delivery, preferably in the 36th week of pregnancy. Extremely early section was abandoned because of increased mortality of the infants. The indications for cesarean section in these patients are: toxicosis, characteristic complications such as gigantic fetus, signs of fetal maturation despite short gestation (roentgenographic measurements of the fetal length), threatened psychoses of the mother at the end of pregnancy with risk of shock and coma, advanced age of primiparas, and history of several stillbirths.

Radioactive Isotopes.—E. Schwach of Vienna injected radioactive gold (Au^{198}) directly into the tumors of patients with still limited recurrences in the pelvic wall after hysterectomy for carcinoma of the uterus. In patients in whom intratumoral application was impossible, a strip saturated with the remaining portion of the isotope was placed on the carcinomatous focus, which had been made accessible by laparotomy. Temporary fixation was performed in order to obtain an optimum local irradiation effect. From 120 to 200 curies was applied per treatment. Despite the large dose, neither a carcinolytic irradiation effect in the recurrent tumor nor a growth-inhibiting effect on the carcinomatous spread was observed. The Au^{198} is distributed too rapidly within the body, and thus a low-dose local irradiation effect may be obtained, which causes temporary relief of pain in most cases. Appreciable rests of the isotope could still be demonstrated with the Geiger counter in the patient's body after two months, and they were stored in higher concentration in the spleen than in the injected pelvic organs. Because of these observations, the speaker refrained from further therapeutic application of Au^{198} in treating recurrent pelvic tumors.

Embryopathy Without Manifest Disease of the Mother.—E. Engelhart of Graz said embryopathies may be classified as viral, deficiency, toxic, and those caused by irradiation. An atypical form has also been observed. In contrast to the typical viral embryopathy, this was a viral embryopathy with no sign of infectious disease of the mother during early pregnancy. The patients had had the viral disease in their childhood and had acquired immunity. The malformations in their infants were caused by a viral disease of a child who lived in close contact with the pregnant woman during her early pregnancy. The woman during her early pregnancy acts as a carrier of the virus and transmits it to the embryo. The first case was that of a malformation and premature birth resulting from the mother's exposure, early in pregnancy, to German measles in an older child. There was no simultaneous disease in the mother, who had acquired immunity at the age of 3 years. The second case was one of intra-uterine fetal death and abortion after several children had had whooping cough without simultaneous disease of the mother during the early pregnancy. This mother had had whooping cough when she was 3 years old and was reexposed to the infection in the 20th week of her pregnancy. Miscarriage of the infant, who had died in utero, occurred after 25 weeks. In the third case the mother was in her fifth week of pregnancy when her first-born child got scarlet fever. She attended this child during the entire infectious period, and the fetus developed a severe cardiac malformation. It was concluded that this type of viral embryopathy will be the cause of malformations more frequently than that caused by German measles, because most women have acquired immunity to this disease in childhood. Furthermore, some of the unknown causes of congenital malformation, which cause to about 42% of the total, can be explained in this way. Protection can be obtained only by effective prophylactic treatment, which consists of separation of the mother in early pregnancy from her children with virus disease.

Thrombopenia During Treatment with Reserpine.—At the meeting of the Society of Physicians of Vienna on June 29, Dr. K. Schmidt reported the case of a 56-year-old patient in whom a hemorrhagic diathesis with thrombopenia developed during treatment with reserpine. There was an increase in thrombocytes and a disappearance of hemorrhagic diathesis after corticotropin was given in place of reserpine. The decrease in thrombocytes was by crisis, and hemorrhagic diathesis recurred after a small test dose of reserpine was given, symptoms being demonstrable after six hours. There was no retraction of the blood clot when reserpine was added in vitro to the patient's blood, and the retraction of the clot was poor without the addition of the drug. These manifestations disappeared after treatment with corticotropin, but the thrombocytes again decreased when treatment with corticotropin was discontinued, even though no more reserpine was given.

Eczema Herpetiforme.—At the same meeting, Drs. W. Lindemayr and C. Eberhartinger reported a series of nine patients with eczema herpetiforme. This disease is produced by the infection of the eczematous skin with the virus of herpes simplex and must be distinguished from similar lesions, particularly from eczema vaccinatum. The virus of herpes simplex could be demonstrated in all of the seven patients so tested. Three patients showed involvement of the cornea or the eyelids. The course was benign in all of the patients. To what extent this was the result of the use of the chlortetracycline given cannot be said because the condition tends to heal spontaneously.

Sudden Pressure Changes.—At the same meeting, H. Kolder reported experiments on explosive decompression carried out on rats in a glass the shape of a truncated cone. The immediate results of explosive decompression were investigated with pressures of 0.1 kg. per square centimeter and a pressure difference from 0.4 to 0.9 kg. per square centimeter with pressure equalization times of 1.3 to 15 milliseconds. Immediately after the decompression, respiration ceases and the electrocardiogram shows a decrease in frequency. Animals that had been subjected to vagotomy continued to breathe after the decompression, but after from 15 to 20 seconds even the vagotomized animals showed bradycardia together with electrocardiographic signs of a cardiac disorder induced by hypoxia. The instantaneous arrest of respiration and the bradycardia are caused by stimulation of the vagus nerve, which in turn is produced by the expansion of air in the dilated lung as the result of the decompression. The changes observed in the electrocardiogram after from 15 to 20 seconds, even in the vagotomized animals, are caused by arterial air embolism. Air bubbles can be demonstrated in the heart.

Artificial pneumothorax protects against the results of explosive decompression, that is, the arterial air embolism cannot have been caused by the liberation of gases in the blood. With the aid of high-speed photography, it was possible to follow the course of the expansion of the thorax after decompression. There was a noticeable outflow of air from the mouth after 3 milliseconds, and after 5 milliseconds the expansion of the thorax begins. This expansion is maximal at the end of 20 milliseconds, and, after from 60 to 70 milliseconds, the thorax again commences its contraction. The results of decompression depend on the outflow of the air that has expanded in accordance with the pressure decrease in the lung, and on the concurrent expansion of the thorax as a result of the decrease in pressure around the body. Exact values can be given for the pressure difference and decompression time that are just bearable. In the presence of a pressure difference of 0.9 kg. per square centimeter, for instance, the decompression time must be longer than 40 milliseconds in order to avoid the afore-mentioned results. Functional manifestations and autopsy findings indicate that the same process takes place during explosive decompression and in injuries produced by air blast.

Evaluation of Clinical Findings.—At the same meeting, E. Bukovics and F. X. Wohlzogen said that statistical analysis is difficult or impossible when clinical findings are not expressed in definite figures. This is particularly the case in the evaluation of a patient who is being treated with a new drug, the efficacy of which is unknown. In such cases there are only three criteria that can be applied to the evaluation: improved, unchanged, or made worse. The question arises whether it is possible to deduce the therapeutic efficacy from the number of improved patients in a group of patients who have received the same treatment. This problem was solved as follows. In accordance with the clinical findings, each patient was given a numerical factor, thus, +1 stood for improved, 0 for unimproved, −1 for made worse. These figures were added. A spot check of the factor n (number of patients) thus receives a certain value z (sum of evaluations). Assuming that, without the administration of the therapeutic substances to be tested, an equal number of patients would be improved, unimproved, or made worse (z=0), it is possible to compute exactly the probability of every fortuitous deviation of the value of z from 0.

ITALY

Infant Death Rate.—Recent statistical reports indicate that the deaths in the first year of life in Italy have decreased from 58.4 to 52.8 per 1,000. This is attributed to improved medical care, the use of new drugs, and improved living conditions. The number of accidental deaths due to such things as falls, drownings, and road accidents exceeds that due to disease.

Hereditary Tumors.—At the meeting of the Medical Academy of Pistoia in April, Professor Cianferrari stated that hereditary predisposition to formation of tumors exists in some persons. This is especially true in tumors of the stomach and breast. Those of the uterine cervix and of the bladder appear not to be hereditary, and tumors of the uterine fundus and of the prostate may or may not be inherited. The speaker emphasized the fact that, even though tumors may be considered biologically hereditary, the probability that such a tumor will develop in any given person is not much greater than the probability of formation of tumors in the general public.

PERU

Treponematosis.—Further evidence that treponematosis originated in the Americas is presented by Prof. Pedro Weiss (*Ginecologia y Obstetricia*, volume 2, number 1, 1956), who found in pre-Colombian cemeteries adults' bones with lesions identical to those now known to be caused by syphilis. There is further evidence that, of the three treponematoses (syphilis, yaws, and pinta), pinta arose first. Syphilis is an urban disease and does not need an insect vector, while yaws and pinta are rural diseases and are transmitted by insects. Since yaws and pinta have epidemiological features that render them likely to arise under the conditions found in the tropical jungle, they may be as old as the jungle, whereas syphilis requires concentrations of population such as were not found until agricultural cultures were formed many thousands of years later.

President-Elect of Peruvian Federation.—Dr. Froilán Villamón, president-elect of the Peruvian Medical Federation, in an address before the federation said that one of the most important problems in medical education is the creation of a code of medical ethics. There is also a great need to place medical research on a firmer scientific basis. Dr. Villamón pledged himself to fight for free choice of physician and clinic by beneficiaries of the social insurance agency.

The Menopause.—In *Ginecologia y Obstetricia* (volume 2, number 1, 1956), Dr. Normando Arenas and co-workers state that, in a series of 1,000 women in the menopause, the average age at menarche was 13 years 9 months and the average age at menopause was 48 years 8 months, giving an average of 34 years 11 months of potential child bearing. The fact that this figure is slightly less in women of European origin is explained by environmental rather than racial factors.

UNITED KINGDOM

BCG Vaccine.—Since 1949, when BCG vaccine began to be used on a large scale in the United Kingdom, the standard liquid BCG vaccine manufactured by the State Serum Institute of Copenhagen has been used. Although this vaccine has given a conversion rate of practically 100% within six to eight weeks, it has become clear that liquid BCG suspensions have certain disadvantages. These include the necessity for using them fairly soon after preparation, a tendency to the production of unsightly scars, and the inability to test them for their content of viable organisms because of the fact that the vaccine is released for use soon after preparation. A freeze-dried vaccine is now available in the United Kingdom, and Lorber and co-workers (*Tubercle* 37:187, 1956) have investigated its use in 276 newborn infants in Sheffield. They report that six weeks after vaccination the reaction to tuberculin was positive in only 80% of the vaccinated infants, but 12 weeks after vaccination it was positive in 94%. The local lesions produced by the freeze-dried vaccine were much smaller than those produced by the Danish vaccine and were neither painful nor disfiguring. They usually disappeared by 12 weeks after vaccination. Enlargement of the axillary lymph nodes was infrequent, and the nodes never discharged or suppurated. On the other hand, in 11 of the 106 infants vaccinated with the liquid vaccine, a large papule with a large central ulcer developed, axillary lymph-node enlargement was common; and the large lesions took many months to heal. The freeze-dried vaccines were kept at room temperature for 19 to 28 weeks without apparent loss of antigenicity.

Incidence of Circumcision, Tonsillectomy, and Appendectomy in Recruits.—The incidence of circumcision, tonsillectomy, and appendectomy among 1,434 Royal Air Force recruits, aged 17 to 24 years, was investigated by Stuart Carne (*Brit. M. J.* 2:19, 1956). Circumcision had been performed in 34.4% (less than 1.5% of the recruits were Jewish). The incidence was higher in those from "public" schools (41.9%) than in those from "elementary" schools (32.8%). The most striking difference, however, was the much lower incidence (25.5%) among the 137 recruits who came from Scotland. Tonsillectomy had been performed in 31.9% of the recruits, and nearly 67% of the operations had been performed when the subject was in the 4-to-8-year age group. There were no national differences, but the incidence was significantly higher among recruits from grammar and public schools (37%) than among those from elementary schools (28.9%). Appendectomy had been performed in 8.4% of the recruits.

Annual B. M. A. Meeting.—The annual representative meeting of the British Medical Association, held in Brighton, was enlivened by an introductory debate as to whether members should be allowed to smoke while the meeting was in session. Convinced that not only lung cancer but also coronary thrombosis and bronchitis are undoubtedly brought on by smoking, the meeting agreed that smoking should not be allowed during the meetings. A statement in its annual report that the council believes the National Health Service likely from time to time to be the subject of political controversy led to much discussion. One member said that if the health service were divorced from politics it need not annually cost 1.12 billion dollars. In his opinion the council could have called a conference of the political parties, approached the Prime Minister and the leader of the opposition, and informed the public that the profession was tired of being the football of the two political parties. A member of the council admitted that it was a bad thing that medicine should be to some extent bedeviled by politics, but so far the council had been unable to find any practical solution to the problem.

In a motion expressing alarm at the continued influx of immigrants found to be suffering from communicable diseases and recommending that appropriate action be taken, a member said that persons with tuberculosis were entering the country in far greater numbers than the Ministry of Health was willing to admit. At one clinic in London, of 78 beds provided for the treatment of pulmonary tuberculosis, 26 were permanently occupied by Irish immigrants. There appeared to be no effective statutory power to prevent the entry into the country of persons suffering from active pulmonary tuberculosis. Britain was almost alone in the Commonwealth in not requiring an examination and certificate of fitness from prospective immigrants before leaving the country of origin. Another member of the council said that all that stood between this resolution and its implementation was the ever-open-door policy to immigrants from practically all over the world to Britain.

The Oxford division moved that access to the National Health Service should not be available to foreign tourists in Britain except in the case of nationals of countries with which there are reciprocal arrangements. This motion did not apply to foreigners who were resident for a long period or who were studying in Britain. Another member stated that about 18 months ago six American women were taken into Southampton Hospital with fractured femurs due to a rough crossing of the Atlantic. Although one of them was fit enough to go home after an eight-weeks' stay in the hospital, she said she could not afford the treatment in the United States and remained in the hospital six more weeks. Other members took pride in being allowed to offer hospitality to those who come to Britain for any purpose. The motion was rejected by a vote of 155 to 135.

The meeting carried a motion expressing chagrin at the refusal of the Home Secretary to legalize the administration of morphine by competent nurses in serious industrial accidents. It was reported that some time ago a deputation from the Royal College of Nursing and the British Medical Association went to see the Home Secretary to request an amendment to provide that competent nurses employed in industry should be allowed to administer morphine in cases in which there was likely to be delay in getting a physician to the scene. The Home Secretary refused to agree to this, pointing out that the proper way to provide for a serious accident was to ensure that there were arrangements for securing the early attendance of a physician. In opposing the motion, a member from the Durham coalfield said that he did not consider it fair to put this extra responsibility on nurses. A patient in shock requires intravenous administration of morphine in many cases, and that is not a procedure for a nurse to carry out.

The Burst Abdomen.—At the annual meeting of the B. M. A., Mr. Harold Park reported that, in 10,166 laparotomies performed at three general hospitals in Brighton over a five-year period, wound dehiscence occurred in 140, or 1.3%. When appendectomies were excluded, the figure was 2.1%. Most bursts occurred about the fifth or sixth day, and upper abdominal incisions were more prone to rupture than those of the lower abdomen. The case fatality rate was about 30%. He distinguished two types. One occurred in debilitated patients, in whom the wound never showed any signs of healing. The other, and more important, type occurred in patients in good condition and was preceded by a serosanguineous discharge from the wound. This type occurred usually in patients in the fifth, sixth, and seventh decades, and more than a third were in patients with malignant disease. Catgut had been used in 72% of the bursts. A precipitating factor was always increased abdominal pressure, usually due to coughing, vomiting, or ileus. Mr. Selwyn Taylor, in discussing this second type, made a plea for a study of the bacterial flora of the serosanguineous discharge, which could appear as early as 24 hours after operation. It did not appear to matter what type of suture material was used. In experimental wounds the introduction of antibiotics had improved the tensile strength of sutures, which suggested that asepsis was important. The speaker could find no record of a burst following a transverse abdominal wound.

Cost of Health Service.—The Minister of Health stated that the cost of the health service per capita of civilian population in England and Wales, exclusive of that met by payments by persons using the services, was estimated for 1956-1957 to be nearly $34 for all services provided as part of the health service. The estimated total cost to the health service in the current fiscal year resulting from increases in the prices of food and other hospital purchases is about $10,920,000. The cost to the Ministry of Health of a full years' supply of welfare milk to an individual child was $23.37; but this increased to $25.53 on July 1, when the price of liquid milk was increased.

New Poliomyelitis-like Disease.—After reviewing several mysterious outbreaks of an illness akin to poliomyelitis, the *Lancet* of May 26 concludes that a new disease involving the central nervous system has made its appearance. It is characterized by symptoms and signs of damage to the brain and spinal cord, protracted muscle pain, and emotional disturbances in convalescence, but it has a relatively benign outcome. One outbreak occurred in northwest London last summer, the second involved young British soldiers stationed in Berlin, and a third occurred in Iceland.

National Versus White Flour.—The independent panel appointed by the government to study the nutritive values of flour supported the industry against the government's medical and scientific advisers. Millers and bakers had claimed that nutritional differences in composition between national flour of 80% extraction (produced when 100 parts by weight of uncleaned wheat have been milled to give 80 parts by weight of flour) and the prewar flour of 70 to 72% extraction, when the latter was enriched with vitamins and iron, were insignificant. The government's medical and scientific advisers and the Medical Research Council claimed that, if the extraction rate were lowered to 70%, and even if thiamine, nicotinic acid, and iron were restored by enrichment, a reduced intake of other vitamins might in some circumstances cause nutritional deficiences. Flour of 80% extraction is, however, unpopular with millers, because it tends to be grey. The panel was impressed by the evidence for the demand for white flour and white bread. The professional pride of the miller in producing as clean and white a flour as possible is one reason for this preference. The bakers prefer a low extraction flour because it is easier to handle and from it they can produce more appetizing bread, rolls, cakes, and biscuits. Even the public prefers bread and cake made with the whiter grades of flour. The scientific arguments by the experts and advisers were not disproved but merely gave way to a popular demand.

Twins Born Twelve Days Apart.—Twins have been born 12 days apart at the Bearsted Jewish Memorial Hospital, Stoke Newington. The mother went into the hospital on May 17, and the first of the twins, both boys, was born on May 18. The second arrived on May 30. Mother and twins are well. This is the longest gap between twin births in the history of the hospital.

the aid of high-speed photography, it was possible to follow the course of the expansion of the thorax after decompression. There was a noticeable outflow of air from the mouth after 3 milliseconds, and after 5 milliseconds the expansion of the thorax begins. This expansion is maximal at the end of 20 milliseconds, and, after from 60 to 70 milliseconds, the thorax again commences its contraction. The results of decompression depend on the outflow of the air that has expanded in accordance with the pressure decrease in the lung, and on the concurrent expansion of the thorax as a result of the decrease in pressure around the body. Exact values can be given for the pressure difference and decompression time that are just bearable. In the presence of a pressure difference of 0.9 kg. per square centimeter, for instance, the decompression time must be longer than 40 milliseconds in order to avoid the afore-mentioned results. Functional manifestations and autopsy findings indicate that the same process takes place during explosive decompression and in injuries produced by air blast.

Evaluation of Clinical Findings.—At the same meeting, E. Bukovics and F. X. Wohlzogen said that statistical analysis is difficult or impossible when clinical findings are not expressed in definite figures. This is particularly the case in the evaluation of a patient who is being treated with a new drug, the efficacy of which is unknown. In such cases there are only three criteria that can be applied to the evaluation: improved, unchanged, or made worse. The question arises whether it is possible to deduce the therapeutic efficacy from the number of improved patients in a group of patients who have received the same treatment. This problem was solved as follows. In accordance with the clinical findings, each patient was given a numerical factor; thus, +1 stood for improved, 0 for unimproved, −1 for made worse. These figures were added. A spot check of the factor n (number of patients) thus receives a certain value z (sum of evaluations). Assuming that, without the administration of the therapeutic substances to be tested, an equal number of patients would be improved, unimproved, or made worse ($z=0$), it is possible to compute exactly the probability of every fortuitous deviation of the value of z from 0.

ITALY

Infant Death Rate.—Recent statistical reports indicate that the deaths in the first year of life in Italy have decreased from 58.4 to 52.8 per 1,000. This is attributed to improved medical care, the use of new drugs, and improved living conditions. The number of accidental deaths due to such things as falls, drownings, and road accidents exceeds that due to disease.

Hereditary Tumors.—At the meeting of the Medical Academy of Pistoia in April, Professor Cianferrari stated that hereditary predisposition to formation of tumors exists in some persons. This is especially true in tumors of the stomach and breast. Those of the uterine cervix and of the bladder appear not to be hereditary, and tumors of the uterine fundus and of the prostate may or may not be inherited. The speaker emphasized the fact that, even though tumors may be considered biologically hereditary, the probability that such a tumor will develop in any given person is not much greater than the probability of formation of tumors in the general public.

PERU

Treponematosis.—Further evidence that treponematosis originated in the Americas is presented by Prof. Pedro Weiss (*Ginecologia y Obstetricia*, volume 2, number 1, 1956), who found in pre-Colombian cemeteries adults' bones with lesions identical to those now known to be caused by syphilis. There is further evidence that, of the three treponematoses (syphilis, yaws, and pinta), pinta arose first. Syphilis is an urban disease and does not need an insect vector, while yaws and pinta are rural diseases and are transmitted by insects. Since yaws and pinta have epidemiological features that render them likely to arise under the conditions found in the tropical jungle, they may be as old as the jungle, whereas syphilis requires concentrations of population such as were not found until agricultural cultures were formed many thousands of years later.

President-Elect of Peruvian Federation.—Dr. Froilán Villamón, president-elect of the Peruvian Medical Federation, in an address before the federation said that one of the most important problems in medical education is the creation of a code of medical ethics. There is also a great need to place medical research on a firmer scientific basis. Dr. Villamón pledged himself to fight for free choice of physician and clinic by beneficiaries of the social insurance agency.

The Menopause.—In *Ginecologia y Obstetricia* (volume 2, number 1, 1956), Dr. Normando Arenas and co-workers state that, in a series of 1,000 women in the menopause, the average age at menarche was 13 years 9 months and the average age at menopause was 48 years 8 months, giving an average of 34 years 11 months of potential child bearing. The fact that this figure is slightly less in women of European origin is explained by environmental rather than racial factors.

UNITED KINGDOM

BCG Vaccine.—Since 1949, when BCG vaccine began to be used on a large scale in the United Kingdom, the standard liquid BCG vaccine manufactured by the State Serum Institute of Copenhagen has been used. Although this vaccine has given a conversion rate of practically 100% within six to eight weeks, it has become clear that liquid BCG suspensions have certain disadvantages. These include the necessity for using them fairly soon after preparation, a tendency to the production of unsightly scars, and the inability to test them for their content of viable organisms because of the fact that the vaccine is released for use soon after preparation. A freeze-dried vaccine is now available in the United Kingdom, and Lorber and co-workers (*Tubercle* 37:187, 1956) have investigated its use in 276 newborn infants in Sheffield. They report that six weeks after vaccination the reaction to tuberculin was positive in only 80% of the vaccinated infants, but 12 weeks after vaccination it was positive in 94%. The local lesions produced by the freeze-dried vaccine were much smaller than those produced by the Danish vaccine and were neither painful nor disfiguring. They usually disappeared by 12 weeks after vaccination. Enlargement of the axillary lymph nodes was infrequent, and the nodes never discharged or suppurated. On the other hand, in 11 of the 106 infants vaccinated with the liquid vaccine, a large papule with a large central ulcer developed, axillary lymph-node enlargement was common; and the large lesions took many months to heal. The freeze-dried vaccines were kept at room temperature for 19 to 28 weeks without apparent loss of antigenicity.

Incidence of Circumcision, Tonsillectomy, and Appendectomy in Recruits.—The incidence of circumcision, tonsillectomy, and appendectomy among 1,434 Royal Air Force recruits, aged 17 to 24 years, was investigated by Stuart Carne (*Brit. M. J.* 2:19, 1956). Circumcision had been performed in 34.4% (less than 1.5% of the recruits were Jewish). The incidence was higher in those from "public" schools (41.9%) than in those from "elementary" schools (32.8%). The most striking difference, however, was the much lower incidence (25.5%) among the 137 recruits who came from Scotland. Tonsillectomy had been performed in 31.9% of the recruits, and nearly 67% of the operations had been performed when the subject was in the 4-to-8-year age group. There were no national differences, but the incidence was significantly higher among recruits from grammar and public schools (37%) than among those from elementary schools (28.9%). Appendectomy had been performed in 8.4% of the recruits.

Annual B. M. A. Meeting.—The annual representative meeting of the British Medical Association, held in Brighton, was enlivened by an introductory debate as to whether members should

Chiropody as Practice of Medicine and Surgery.—This is a declaratory judgment proceeding in which the plaintiff, Medical Care, Inc., seeks determination of the question whether it is required to pay, under its contracts, charges incurred by subscribers for treatments that they have received from certain practioners of chiropody. The trial court held that the plaintiff is obligated under its contracts with subscribers to pay for services rendered by chiropodists, provided such services consist of medical, mechanical, or surgical treatment of ailments of the human hand and foot with the use of local anesthetics. From this order the plaintiff appealed to the Supreme Court of Appeals of West Virginia.

The questions presented by the certificate of the circuit court, said the Supreme Court of Appeals, are (1) whether a chiropodist is a duly licensed physician within the meaning of the state's enabling act for medical care plans, and is eligible to participate in the medical service plan operated by the plaintiff, and (2) whether the plan operated by the plaintiff embraces within its scope or contracts treatment by a chiropodist and entitles him to payment by the plaintiff for such treatment according to its contracts with its subscribers and the schedule of payments provided in such contracts.

Under the contracts between the plaintiff and its subscribers, in consideration of certain dues paid by them, said the court, the plaintiff agrees to pay for certain medical and surgical treatment on the basis of a schedule of fees specified in the contracts for various medical and surgical services. A physician can become a participant in the plan by agreeing to comply with the specified schedule of fees. If the medical services are furnished to subscribers by a physician who does not participate, the plaintiff agrees to pay 75% of the fee specified in the schedule. The contracts do not expressly cover services furnished by chiropodists, and services by them were not taken into consideration when the rate of the dues required to be paid by subscribers was fixed by the plaintiff and approved by the insurance commissioner. The plaintiff asserts that if its plan should be extended to cover treatment by chiropodists it will be necessary to revise the rate of the dues in order to preserve the financial solvency of the plan as presently operated by it.

A consideration of the applicable statutes, said the court, indicates clearly that a duly licensed physician or surgeon is authorized to treat any human ailment or infirmity by any method and that a duly licensed chiropodist, though authorized to treat medically, mechanically, and surgically without the use of anesthetics other than local, the ailments of the hand or foot, except the amputation of the foot, hand, toes, or fingers, and to fit and recommend appliances for correction or relief of minor foot ailments, is limited to those areas and those ailments in the practice of medicine and surgery. A duly licensed physician and surgeon is authorized to engage in the practice of chiropody, but a duly licensed chiropodist may not practice medicine and surgery except within the limits expressly imposed by the statute.

The statutes relating to the licensing of chiropodists exclude chiropodists from the category of duly licensed physicians and surgeons by forbidding chiropodists to use the title "doctor" except in connection with the word "chiropody or chiropodist." The statute broadly defining the practice of medicine and surgery as the treatment of any human ailment or infirmity by any method, expressly states that its provisions shall not apply to regularly licensed or registered chiropodists.

It is clear, concluded the Supreme Court of Appeals, that a duly licensed chiropodist is not a duly licensed physician within the meaning of the West Virginia statutes and is not eligible to participate in the plan of a medical service corporation for medical and surgical care furnished by duly licensed physicians to its subscribers under the terms of their contracts with such corporation. A medical service corporation is authorized to contract with the public and duly licensed physicians only for such medical and surgical care as may be furnished by duly licensed physicians and for the payment for such service as may be specified in the contracts made by its subscribers with such corporation, and the exclusion from such contracts of any charge made by a duly licensed chiropodist for treatment which he has furnished to any of the subscribers of such corporation is proper. Accordingly the order of the trial court in favor of the defendants was reversed. *Medical Care, Inc. v. Chiropody Association of West Virginia et al.; 93 S. E. (2) 38 (W. Va., 1956).*

MISCELLANY

This is the first part of a two-part article. The second part will appear in a subsequent issue of The Journal.—Ed.

SOCIAL IN-SECURITY—THE TRAP AWAITING THE YOUNG M.D.

DON'T MISDIAGNOSE THIS SOCIAL DISEASE, IT'S CATCHING!

Richard C. Webster, M.D.
and
Richard J. Coffey, M.D., Brookline, Mass.

Is your wife attractive? Do you love your children? Are you unhappy about higher income taxes? If your answers are "Yes," then you should invest the time to read on. Some scraps of paper and a pencil will allow you to determine for yourself whether social security will be a good value for you—or just an expensive delusion.

The authors of this paper are young men, one 34 and the other 37 years old. We have tried to answer for ourselves the following questions: 1. Would social security be good for my wife? 2. Would social security be good for my children? 3. Would social security be good for me?

We have searched for, found, and put together the figures necessary to allow us to make our decisions. We think that the formulas that we employed can be used by other physicians in making their own decisions about the prices or costs for them of social security and the possible values of it in their family planning.

Table 1.—*Social Security Taxes with Tax-Base of $4,200*

3% of $4,200 each year from 1956 through 1959 (4 years) 0.03 × $4,200 $126 × 4	$504.00
3¾% of $4,200 each year from 1960 through 1964 (5 years) 0.0375 × $4,200 $157.50 × 5	$787.50
4½% of $4,200 each year from 1965 through 1969 (5 years) 0.45 × $4,200 $189 × 5	$945.00
5¼% of $4,200 each year from 1970 through 1974 (5 years) 0.0525 × $4,200 $220.50 × 5	$1,102.50
6% of $4,200 each year from 1975 on 0.06 × $4,200 $252 yearly	Variable amount depending on how many years you keep earning

Guaranteed Costs—Social Security Taxes

At the time of writing, Jan. 12, 1956 (it is necessary to state the date for accuracy's sake, because both the social security tax rate and the social security tax base can be raised any day by Congress), you, as a self-employed physician, if you came under social security, would pay 3% on the first $4,200 of your yearly income for your social security taxes.

The social security tax rate has been set by law as follows: 1956 through 1959, 3%; 1960 through 1964, 3¾%; 1965 through 1969, 4½%; 1970 through 1974, 5¼%; 1975 on, 6%. If the tax base figure stayed at $4,200, you would pay the amounts shown in table 1 in social security taxes.

There are some facts you must know about the social security taxes under the present laws if you are to make decisions based on knowledge rather than on hope or faith. You must report your earnings and pay your tax each year when you file your individual income tax return. The money you pay the federal government in social security taxes is not a deduction as far as your income tax is concerned. In other words, if your net income was $4,200, you would pay income tax on the $4,200 and you also would be required to pay your social security tax on the same amount. There are no deductions allowing you to reduce your social security taxes. As long as you earn over $400 a year, you must pay social security taxes. This applies even after you are 65 years old, even after you are 72.

Possible Costs—Probable Increases in *Social Security Tax Base* and Tax Rate

One fact that is not advanced with the claims by the advocates of extension of social security to include physicians *should* give you real cause for concern. The social security tax base figure has risen 40% in just five years. In 1950, the maximum earned income you paid social security taxes on was $3,000. By 1955 it was up to $4,200. A proposal now before Congress would raise it to $4,800 this year. Absolutely nothing in the laws prohibits Congress from raising this figure each year.

Each physician should ask himself the following questions: 1. If I were a politician anxious to please the largest number of voters, would *I* favor raising the social security tax base figure so that more benefits can be promised? 2. How many votes will I lose by antagonizing those with incomes over $4,200? Over $4,800? Over $6,000? Over $10,000? 3. If I can promise more benefits to the lower income groups, how many votes can I pick up? 4. Since well over half of the voters earn less than $4,200 a year, isn't my course of action as a politician perfectly clear? The answers to these questions, and recent history, give you the probable, not just possible, future trend of the social security tax base figures.

You have no guarantee that the social security tax rate will not increase beyond the figures provided by the present laws. In fact, the Cooper bill, which promises increased benefits and which shot through the House of Representatives in 1955 by a vote of 372 to 31, would change the social security tax rates as shown in table 2.

Put yourself in the politician's shoes. This year, 1956, is an important election year. You read in the American Federation of Labor's *American Federationist* that the first real political test for the newly merged CIO and AFL labor giant will come on H. R. 7225, the Cooper bill. How would you vote? Can you think of any good political reasons for not increasing the social security tax rates even beyond the Cooper bill changes?

TABLE 2.—*Social Security Tax Rates at Present and as Proposed in the Cooper Bill*

Present Law		Cooper Bill
Yr	Rate, %	Rate, %
1956-1959	3	3¾
1960-1964	3¾	4½
1965-1969	4½	5½
1970-1975	5¼	6
1975 on	6	6¾

We could not. Therefore, in our *determination* of social security costs for the physician, we came *to these conclusions:* 1. The present laws *guarantee that the* social security tax rate will increase. (It was revised upward as recently as 1954, by the way.) 2. The 40% rise in the social security tax base in the last five years sets the historical pattern for similar increases of the tax base in the future. 3. *Political* expediency *demands* further increases in both the social security tax rates and tax base figures. 4. We're goin' to get 'em, sure as shootin'!

How high will they go? Your guess is certainly as good as ours; but, on the basis of a $1,200 rise in five years, the tax base figure would be $9,000 by 1975. Six per cent of that would equal a social security tax of $540 per year. Six and three-quarters per cent of $9,000 would be $607.50 per year. If you figure a 40% rise from the previous social security tax base figure every five years, your tax base figure would be $22,588.61 by 1979. Six per cent of $22,588.61 would equal a social security tax of $1,355.32 per year. If the tax rate had risen to 10% by then, the tax would be $2,258.86 per year.

A third way to estimate future costs, based on recent social security history, would be to add $600 each year to the tax base figure. In 1954, the first $3,600 of income was taxed. In 1955, $600 was added. A *proposal* before Congress now would add another $600 in 1956. Using this progression, the tax base figure would be $7,200 in 1960, $10,200 in 1965, $13,200 in 1970, and $16,200 in 1975. Six per cent of $16,200 would equal a social security tax of $972.

We all should recognize that the taxes may not be as high as these figures indicate—or that they might be higher. What the figures do show beyond a question of a doubt is that you cannot make any plans based on costs. And no one in the world can be certain of more accuracy in predicting the future social security tax rates or tax base figures or what you will actually pay in social security taxes each year than you can right now!

It should be recognized that a radical change has taken place in political thinking in the last few years. What applied in the early history of social security no longer can be used as the basis for future thinking. What was originally set up as a plan to provide a minimum of protection for the poor is now being extended into all phases of our social and economic body. The guiding principle in the 1930's was that social security should furnish a basic floor of protection against want in old age or in the survivors in the case of premature death of the breadwinner. Today, an enormous number of people whose chances of benefiting from the social security plan are essentially nil are paying compulsory taxes into the plan, and its proponents wish to extend its purse power into many other fields. In 20 years, coverage has increased from 33 million to 70 million people. New groups are being added, new promises are being made, and new taxes are following.

Lest you say that the costs cannot reach dangerously high levels, think of these facts. The "Minimum Standards of Social Security" convention, adopted by the International Labor Organization several years ago with the support of the labor and government delegates from the United States, includes greater old-age and survivors' benefits than we now have, disability *benefits such as those proposed in the Cooper bill*, weekly benefits for unemployment for any reason, *benefits for maternity* leave from the job, lump-sum job separation pay, and—compulsory health insurance.

Estimates indicate that such a program in this country would cost a minimum of 30% and as much as 40% of payroll. What is 40% of your net income before income taxes? The rate is 35% of much of France's payroll now. Some South American countries that have adopted just parts of the International Labor Organization's program have taxes running as high as 25% today.

It can happen here!

Possible Value of Social Security for the Younger Physician

Social security benefits have been touted to us, the younger men, in glowing terms. We have been told, "You can't buy cheaper *life insurance*," "*Everybody else is on* the gravy train, why shouldn't we hop on?" "*Those old fogies in the* A. M. A made their bundles when they could salt it away; now they're the ones who are keeping us out." If ever physicians missed the boat on a diagnosis, we believe that this is it.

We think you will sense the injustice to our older colleagues as you read on. First, however, we must break the benefits into two main categories. You pay taxes toward both; but you or your family, in essence, can only collect one kind. For simplicity's sake, allow us to call them survivors' benefits and retirement benefits.

Survivors' Benefits—Are You Sure This "Cheap Life Insurance" Is Inexpensive?

We have heard repeatedly that, when we join the social security club, we get almost $37,000 of life insurance coverage Perhaps you have been told the same thing. Were you also told that, to qualify for this maximum family coverage with the least expense, you first must pay maximum social security taxes for 18 months? The next day your wife must give birth to twins and you must die. Even the shock of twins is unlikely to cause this sudden demise on your part, but let us pretend that it does.

Your widow and twins would be paid survivors' benefits of $200 per month for 18 years, or $36,920. Unfortunately, there is some fine print. Your widow has to apply for the survivors' benefits. She may be attractive enough to remarry; but, if she does, she becomes ineligible to receive benefits. If either child marries, he gets no benefits. As soon as your twins become 18 years old, all benefits to them and to your widow stop. She gets nothing, then, until the age of 65, when she might become eligible to receive $81 per month.

If either child or your widow earns more than $1,200 per year, maximum benefits drop. If she or either of the twins earns $2,080.01 or more per year, no survivors' benefits will be paid to the earner. If any one of the three earns over $400, he must pay social security taxes, though. Some other limiting "clauses" will be mentioned later, but let us get on with a cost comparison.

Most self-employed physicians earn at least $5,000 per year. *Therefore, it is quite likely that you would have paid the maximum social security taxes for the 18 months before you died and the twins arrived.* Using present figures and pretending that you came under social security at the beginning of 1956, you would pay $126 in 1956 and half of $126, or $63, in the first half of 1957. This would mean a "premium" paid of $126 plus $63, or $189, before your family could become eligible to receive any survivors' benefits. If the tax base figure is raised to $4,800 and the tax rate to 3¾%, as is likely to happen this year, your "premium" would be $4,800 × 0.0375 = $180 for 1956 and half of $180, or $90, for the first half of 1957, a total of $270.

As a young physician, you can buy much better, guaranteed coverage for your family from private insurance companies. This you can do by purchasing decreasing term insurance (family income rider) without any other life insurance to guarantee your family $200 per month for 18 years. This maximum coverage goes into effect with the payment of your first premium. The yearly premiums would be $92 if you are 25 years old, $120 if you are 30 years old, and $164 if you are 35 years old.

An editorial in the Nov. 26, 1955, issue of The Journal of the American Medical Association cites premiums even lower than the figure we obtained. Their figures follow: $65 if you are 25 years old, $85 if you are 30 years old, and $115 if you are 35 years old. These figures from The Journal are the yearly premiums to establish monthly benefits of $200 for 20 years, 2 years more than the best that social security could do for your widow and twins. Here, these premiums would be in addition to those paid on a $20,000 ordinary life insurance policy. So few fathers are over 40 years of age when the last child is born that "a more realistic counterpart to the survivorship benefits for a widow with minor children" would be a 10-year "family income" clause for a physician 40 years old. The annual premium would be about $60. For a 45-year-old, the yearly premium would be only $83.

Thus, the twins that are born the day you die and your widow can qualify for maximum survivors' benefits if you have paid a minimum of $189 in social security taxes. Take your age and see what you would have to pay as your first premium for better coverage with private insurance companies. Should you really envy those already "lucky enough" to be in the compulsory social security plan?

Suppose, under either plan, social security or private insurance, you live until the twins reach age 18—and then you die. Unless your wife is 65 or over by that time, neither your wife nor your children would receive any payments in return for the money you have put in. How much would you have paid into the two systems during the period that they did have theoretical coverage?

Giving every possible benefit of the doubt to social security, saying that there will be no increases in the tax rate or tax base beyond those already certain under the old law, let us see what 19½ years of social security taxes add up to. Pretend that in the middle of 1956 doctors come under the social security system on a compulsory basis. You will pay $63 for half of 1956, $126 from 1956-1959 (in 1958 you become eligible and your twins are born); $157.50 from 1960-1964; $189 from 1965-1969; $220.50 from 1970-1974; and $252 in 1975. If you die at the beginning of 1976, your absolute minimum social security tax will have been $3,528.

With private insurance, according to our figures, which are less favorable than those cited in The Journal, your costs would be 18 × $92, or $1,656, if you became 25 years old the day the twins were born, 18 × $120, or $2,160, if you became 30 years old on that day, and 18 × $164, or $2,952, if you became 35 years old on that day. Note that the younger you are the less you pay.

According to the figures given in the editorial in The Journal, your costs, according to your age the day the twins were born, for 20 years of guaranteed coverage of $200 per month (2 years or $4,800 more coverage than social security offers) would be 20 × $65, or $1,300, if you were 25 years old the day the twins were born; 20 × $85, or $1,700, if you were 30; 20 × $115, or $2,300, if you were 35; and 20 × $166, or $3,320, if you were 40. Compare these figures with the $3,528 you know you would have to pay under social security (remember that this is the absolute minimum, not the much more likely higher figures). Does social security "insurance" sound so inexpensive now?

Before we leave this "twin situation," please let us indicate the further cost of one of the hidden factors in social security. Bear in mind that the private insurance costs end 18 or 20 years after the twins are born. It is crucially important to remember that your social security taxes continue each year that you earn over $400. *Since only one doctor out of seven between the ages of 65 and 75 is retired, it is unlikely that you will retire.* In fact, as you will see later, it may be impossible for the younger physician to retire. If you earn over $2,080, you can get no retirement benefits until you are 72 years old. So let us take the case of the *young physician* who had the twins and who lives to age 72, and then dies. He has a 6/7 chance of having earned until he dies and hence a 6/7 chance of paying social security taxes until then.

Again using the unlikely but most favorable social security figures without the *expected rise in tax rate or tax base figures beyond those of the present law, let us see what his social security taxes would be.*

Pretend that the twins were born at the beginning of 1958 and that the physician has been paying taxes into social security for 18 months. This year of 1958 is picked to slant the figures in favor of social security, *since the taxes are lower in the earlier years.*

If he were 25 years old the day the twins were born, he would have paid a total of $3,528 plus $7,308, or $10,836, in social security taxes. For that amount of money, he could have bought over six times as much private insurance *for his wife and twins,* or over $1,200 per month guaranteed income for them. These amounts are arrived at using our figures for the insurance premiums, not the more favorable ones from The Journal.

If the physician were 30 years old the day the twins were born, he would pay social security taxes of $3,528 plus $6,048, or $9,576. With that he could have bought four times as much private insurance coverage for his wife and twins, or over $800 per month of guaranteed income for them for 18 years. The figures for age 35 are $3,528 plus $4,788, or $8,316. With that he could have bought over two and one-half times as much coverage, or over $500 per month of guaranteed family income.

On the basis of the figures from The Journal for the insurance premiums, the physician, age 25, would pay $1,170 in 18 years. *He could have stopped his payments at the end of 18 years.* Under the social security system, he would have been taxed a minimum of $10,836 by the time he was 72. For that amount he could have bought over nine times as much coverage for his family.

According to premium figures in The Journal again, the physician, aged 40 at the time the twins were born, would pay $2,988 for 18 years of family income protection. At age 72 he would have paid, under the social security system, $7,056. He could have bought two times as much protection for his family *using available private insurance plans.*

We have spent all this time comparing private insurance premium costs and social security tax costs for the unlikely twin situation because it is only under these conditions that you could get the maximum coverage from social security. This is the bonanza that seems so attractive to many of the younger doctors.

From a practical point of view, there is almost no chance for your family to collect the theoretical maximum benefits described so far. Your chances of dying just 18 months after you begin paying social security taxes and of your wife's having twins on that same day are about nil. It is time now to get into the realm of the more likely situations. How, then, would you determine comparable costs and possible values of the two systems under your own, actual, personal family circumstances?

No matter what your family circumstances, *once you come* under compulsory social security, you pay the taxes. Pretend that the starting day was the beginning of the second half of 1956. You will pay the taxes, as mentioned previously, until the beginning of 1958 before you become eligible for survivors' benefits. If you have paid and continue to pay maximum social security taxes, your youngest child, your next-to-the-youngest child, and your widow might be paid $200 a month of survivors' benefits until your next-to-the-youngest child reaches age 18. The social security maximum coverage per dollar put in by you that they could get would be paid if you died at the beginning of 1958. Determine for yourself the age of your next-to-the-youngest child at the beginning of 1958. Subtract that age from 18. This will give you the number of years of possible $200 monthly payments.

Now determine the age of your youngest child at the beginning of 1958. Subtract this age from the age of your next-to-the-youngest child at the *beginning of 1958*. This figure will tell you the number of years that your widow and youngest child might be paid a maximum of $162.80 per month after your next-to-the-youngest child became age 18 and the $200 monthly payments stopped.

You now have the means of determining what your maximum family coverage might be. Take the number of years of $200 monthly payments and multiply this figure by 12 times 200. Now add the number of years of $162.80 monthly payments by 12 times 162.80. The sum is the maximum family coverage that you can hope for from social security.

Divide this figure by the number of years that would elapse between the beginning of 1958 and the time when your youngest child becomes 18. This will tell you what your family might receive per year until your youngest child becomes 18. Divide this figure by 12 and you will have their possible *monthly income* from social security survivors' benefits, should you die at the beginning of 1958. Now call your insurance man and ask him what comparable private insurance coverage under a family income rider would cost you. We think you will be *pleasantly* surprised.

You can get a rough idea if you know the following: For 18 years of private guaranteed coverage for your family, your yearly premiums per $1,000 of initial coverage beginning at age 25 would be $2.50. At age 30, your yearly premium per $1,000 of coverage would be $3.25. If you started with this 18-year plan at age 35, you would pay $4.43 per $1,000 of coverage. At age 40 you would pay $6.40 per $1,000 of coverage. You do not have to have any other life insurance to get these premium figures.

Obviously, most of you will find that you will not want 18 years of coverage or, at least, that social security would not give you 18 years of coverage, because your youngest child would be older than one day at the beginning of 1958.

The figures cited in THE JOURNAL indicate that, to get $200 coverage a month, a physician beginning a 10-year family income clause at age 40 would pay an annual premium of $60. At age 45, a 10-year guaranteed $200 monthly income for your family would cost $83 per year. Thus, for $24,000 of initial coverage beginning in these age groups, the yearly premiums would be $60 and $83 respectively. The yearly premium per $1,000 coverage would be $2.50 for the 40-year-old physician. For the 45-year-old physician, it would be $3.46.

Having derived a rough estimate of your yearly premium, or an exact one from your insurance man, compare your premium *costs with your costs in the* social security scheme (the tax figures mentioned earlier in this article). The observation is apparent immediately that the younger you are, the more you have to lose by being forced into the compulsory social security system!

Hidden Hookers in Social Security Survivors' Benefits

You must die in either the private insurance plan or the social security survivors' benefits plan for your family to collect any benefits. But in most respects, the resemblances end here. We have mentioned that your wife cannot remarry. Your children cannot get married before age 18. As soon as the youngest child becomes 18 years old, all payments under social security stop. Your widow would not get anything until age 65, when she might become eligible to receive $81.40 per month. None of the three can earn more than $1,200 per year without a drop in the maximum benefits. No one can earn over $2,080 if he or she is to receive any survivors' benefits.

Keep in mind that a compulsory social security system for physicians *would force* all physicians to pay social security taxes. The taxes would be the same whether you had any dependents or not. If you are unmarried, a dependent parent aged 65 or over could receive social security survivors' benefit payments after your death. The maximum monthly payment to a dependent parent, age 65 or over, is $81.40. If your wife survives you and you have no children, she is entitled to no survivors' benefits until she reaches age 65. Some doctors' wives have careers of their own. If so, they are probably ineligible for survivors' benefits; and, in fact, they almost certainly would continue paying social security taxes. In brief, you would pay the social security taxes whether you had any chance to benefit from the payments or not. No matter how your family circumstances change, you still pay the compulsory tax.

It should be noted that these are just some of the limitations. There are others, but you need to be a lawyer to dig them all out. The benefits are not paid automatically on your death. The beneficiary must know he is a beneficiary and must apply for benefits. It is interesting to note that many possible beneficiaries never get around to applying for the benefits.

The amount of the benefit payment is determined in each case by various formulas. For those who earn something, the following directions are printed in a social security booklet "simplifying" the laws for the layman: "There is no single rule for determining whether a person is performing substantial services in self-employment. There are many factors to be considered for different kinds of trades and businesses. The social security administration will make decisions based on the particular facts in each case." Does this sound exact enough for you to bank on in planing your family security? What does your widow do when she runs into the "fine print"?

Retirement Benefits—What They Are and How You Become Eligible for Them

If you retire at age 65 or thereafter and are eligible, you and your wife may be paid retirement benefits. You must survive to collect. If you are eligible, alive, retired, age 65 or over, and have paid maximum social security taxes long enough, you can receive $108.50 per month under the old-age benefits. You and your wife, if she is alive and age 65 or over, can receive $162.80 per month. If your wife survives you, and she is age 65 or over, she can be paid $81.60 per month. These are the maximum figures.

To become eligible, you must fit into any one of these three categories: 1. You must have worked under social security and paid taxes for a total of at least 10 years. 2. All the months that you have worked under social security at any time, when added together, must equal at least half the time between Jan. 1, 1951, and the date you reach age 65. 3. You must have worked steadily under social security through every quarter from Jan. 1, 1955, to the date you reach age 65.

For most young physicians, the requirement of import would be that they work under social security for a total of at least 10 years. However, if compulsory social security for physicians began in the middle of 1956, obviously most would work a good many more than 10 years under social security before reaching age 65. In fact, most who survive to the "golden age" will continue working. If they earn over $2,080, they will not be eligible to receive retirement benefits until age 72. Then, whether they retire or not, they are eligible to receive the benefits. But, if they continue earning over $400 a year beyond age 72, they pay social security taxes on their earnings.

Retirement Benefits—What Is the Young Doctor's Chance of Collecting?

The young doctor's chance of collecting retirement benefits is very poor!

You must survive to age 65. To collect maximum monthly retirement benefits, you and your wife both must survive and you must both be 65 or over. To collect any retirement benefits, you must earn less than $2,080.01 a year—at least until you reach age 72. To collect maximum retirement benefits, you must earn less than $1,200 a year until age 72.

How likely are you to survive to age 65? If you are 20 years old now, your chance of surviving to age 65 is 61%. If you are 25, your chance is 62%. If you are 30, your chance is 63%. If you are 35, your chance of surviving to age 65 is 64%. If you are 40, the figure is 65%. If you are 45, your chance is 68%.

Thus, the odds are that, of three younger physicians (under 45 years of age), one will never reach 65. Your wife's chances are about the same. But the chances are much less than two to three that you and your wife will both reach 65. In fact, they are less than 50%.

The younger you are, the less chance you have. Again, we see that the older physicians have less to lose or more to gain than the younger man. A man age 55 has a 77% chance of reaching 65. A man age 60 has an 85% chance of reaching 65. Have our older colleagues really been misleading us? So far, the figures do not bear out the charges.

Now, let us pretend that you are in the lucky two-thirds. You reach age 65. The most recent figures show that only one doctor in seven in the age group 65-75 is retired.

If you are willing to accept these figures, you have about 2/3 x 1/7, or 2/21, or less than a 10% chance of collecting any retirement benefits from social security before age 72. To collect the maximum retirement benefits of $162.80 per month, both you and your wife must survive. You and your wife have about 2/3 x 2/3 x 1/7, or 4/63, or less than a 7% chance of collecting the maximum monthly benefit.

You could say that the number of doctors retired today has no bearing on the percentage that will retire in the future. However, the chances are that, the younger you are now, the more difficult it will be for you to retire in the future, even if you wanted to retire at age 65. The younger you are, the longer your training has taken. The younger you are, the more dollars your training has cost. We all know the history of income and other taxes. How do you, the young physician, get enough money put aside to retire on? Can you say that $162.80 per month will suffice to keep you and your wife comfortable 40 years from now (if you are age 25 now), 20 years from now (if you are age 45 now)? Remember that one dollar 20 years ago is today worth only about 50 cents. What will $162.80 be worth 20 years from now? Forty years from now? If $162.80 per month is not enough to keep you and your wife comfortable when you reach age 65, you may have to stay in practice. How do you, in practice, keep your earnings under $2,080 per year? If you don't, you won't get any social security retirement benefits.

Almost every indication is that, with increasing lengths of time required in training, the physician's earning years will be shorter in the future. Thus he will have to earn more per year. If he earns more, graduated income taxes take bigger bites. If the income tax rates rise, and there are reasons, as you will see later, to suspect that they will, then the tax bite will be greater still. If living costs rise, money left over for the future retirement will be harder to come by. If the dollar continues losing its value (inflation), any money you can manage to put aside will purchase less at retirement age. With these factors in mind, what do you think about your chances for retirement? Will they be greater or less than those of the physicians age 65 or over today?

If you do not retire, you will be paying the social security taxes, whatever they might be by then, long after most formerly employed people in other occupations have stopped paying them and have started collecting their retirement benefits.

In essence, that part of your social security tax dollar going toward retirement benefits, with today's figures (favorable to social security), would be split about like this: over 90 cents of it is likely to go to pay for other peoples' retirement benefits; you are likely to get back less than 10 cents.

Costs for Retirement Benefit Coverage

Earlier in this article we indicated the tax costs of social security coverage. These figures apply to retirement benefits, also. Again we find that, the younger the physician, the higher the costs are likely to be. The doctor, age 55 at the beginning of a compulsory social security system for physicians, would only have to pay the social security taxes for 10 years before reaching age 65. The younger you are at the beginning of a compulsory system, the more social security tax years you face before you reach age 65. The present laws guarantee a rise of the social security tax rates and of the tax base figures. We have indicated that the known figures are likely to be raised well beyond the presently known rates of increase. If you will look at the earlier figures, you will find that they support these statements. Suffice it here to say that the greatest costs will be inflicted on the younger physicians.

To be realistic, in comparing costs of social security and of private retirement plans, you, as a young doctor, should decide what your chances for actually retiring are. We believe your chances of retiring are less than one in seven, for reasons just mentioned. However, let us pretend that they are one in seven. Since private plans guarantee payments whether you are retired or not, they are seven times more valuable to you; or, said another way, social security is one-seventh as valuable as far as retirement benefits go. Now let us look for costs of a private plan that would pay benefits equaling one-seventh of the theoretical maximum social security retirement benefits. To get the maximum social security retirement benefits, both you and your wife must be age 65 or over. Therefore, in deriving the figures to be listed for the private plan, let us assume that you and your wife are the same age.

Annual premium payments for a private annuity deferred to age 65 providing a monthly income of one-seventh of $162.80 while both you and your wife are living, one-seventh of $108.50 per month while you alone live, and one-seventh of $81.50 per month while only your wife lives would be $60.52 if you are 25 years old at the start, $74.05 if you are 30, $92.59 if you are 35, $119.24 if you are 40, $160.27 if you are 45, and $230.29 if you are 50.

The one-in-seven thinking no longer applies after age 72. Then, if you have made maximum contributions to social security for the required time, you and your wife, both age 72, can collect maximum social security retirement benefits. A telephone call to your insurance man will get you the annual premium figures for you and your wife at your own present ages for an annuity deferred to age 72 paying benefits comparable to those that social security promises. Believe us when we say that this premium figure will be less than seven times the annual premium figures mentioned just before. Yet for six-sevenths of the doctors this is the cost figure that should be of most interest in comparing real values of the two systems. This is the figure that should be compared with what you guess your total social security taxes will amount to in the years ahead until you reach age 72. This is the time to go back to the earlier figures relating to social security taxes and the observations connected with them.

While we are still on the subject of taxes, you might be interested in knowing that once under compulsory social security, the physician and his wife could only arrange a maximum tax-free yearly income, after age 65, of $5,503.59. As long as you can stay out of the social security system, you and your wife can arrange a maximum yearly tax-free retirement income, after age 65, of $18,148.48. This you can do with retirement income policies and stocks paying dividends.

Retirement Benefits Versus Survivors' Benefits—One at the Expense of the Other

While you still have a choice about compulsory inclusion of physicians under social security, it behooves you to think clearly about costs and values. If you are an insurable younger physician, you probably are much more interested in getting protection for your wife and children in case of your early death than you are in the retirement benefit parts of social security.

We have shown previously that you can buy much more insurance for family protection from private insurance companies than you can get from social security for the same amount of dollars contributed in the form of social security taxes. Remember, you have no cash value to tap for family or personal emergencies in social security as you do with many kinds of insurance. Since so much of your social security tax dollar goes toward retirement benefits, your goal of family protection becomes harder to achieve, not easier.

You might justify this in your mind by saying that part of your family goal is to arrange things so that you and your wife will not be dependent on your children in your old age. With such a small chance that the money you are putting into social security will ever be used for your retirement, with a greater than 90% chance that it will be used for other peoples' retirements, are you really looking out for your family properly?

Remember, you cannot collect both survivors' benefits and retirement benefits. It's one or the other—and because you are a physician, it is likely to be neither!

1101 Beacon St. (46) (Dr. Webster).

THE LEISURE CORNER

THE DOCTOR WRITES A LETTER

Although doctors have at all times incurred the abuse of nonmedical people, they have also received almost extravagant praise. Much truth has been said in jest—and much untruth as well. Still, no other group of professional men and women can show a greater personal sacrifice, a greater devotion to duty, and a sounder consideration for the welfare of humanity. Throughout the centuries, evidence of this has been expressed in personal letters written by doctors to their colleagues, their patients, and to organizations with which they have been affiliated, whether professional, social, or political. Many well-known doctors, whose medical achievements are unrivaled during a busy professional life, often fail to contribute their experiences to the general medical literature. However, they do sometimes sit down and write to a colleague a revealing letter, the kind that makes medical history. In this connection, the first mention of the use of the stethoscope by Rene Laënnec was made in a letter to his cousin. "My cylinder is a real find," he wrote. "Too bad it wasn't hit upon by certain people who would have known how to make a lot of money out of it. As for me, I'm only a fool in such matters, and I will not get more out of it than a little smoke which, to my further detriment, I will not estimate for more than it is really worth." Twenty years later Laënnec was acclaimed for his contribution to medicine.

The decision of a doctor to retire from medical practice has much to do with the state of his physical and mental powers as well as with his individual needs and circumstances. To set an age limit for retirement may seem a little absurd in view of the past accomplishments of older men and women in the practice of medicine. There is no doubt that for originality and vigor younger physicians hold an advantage, but for wisdom and judgment, mature age often holds a distinct advantage. When a doctor reaches the age of retirement, he, like others, would like a feeling of security, with the knowledge that many of the pressing difficulties of life have been overcome. Despite this objective, it may be difficult to know precisely when to reach a decision for voluntary retirement. On the other hand, it is painful and somewhat tragic to witness the slow disintegration of those who have hung on too long in medical practice. Harvey Cushing, the great brain surgeon, once wrote a letter to his friend Dr. Henry Christian of the Peter Bent Brigham Hospital, Boston, expressing some thought on the subject of retirement among doctors.

"Why not put the surgical age of retirement for the attending surgeon at sixty, and the physician at sixty-three or sixty-five, as you think best? I have an idea that the surgeon's fingers are apt to get a little stiff and thus make him less competent before the physician's cerebral vessels do. . . . Then, of course, many of us get, vascularly speaking, a little inelastic well on the side of sixty, or may remain in this respect as youthful at seventy as others are at fifty. This is all a lottery of inheritance and habits, and I shall be very glad, for one, to have legislated to stop active work at sixty."

While many doctors carry on a medical practice at the age of 70, they usually do so on a limited scale. They are philosophical about their semiretirement, knowing there is little point to cracking hazel nuts with dentures. Semiretired physicians do not dislike the world they live in, nor do they assume an attitude of indifference. This point of view was effectively stated in a letter written by Dr. Frederic C. Sharpless to the editor of THE JOURNAL of the American Medical Association a number of years ago: "It is my impression that few doctors retire voluntarily, and, of those who do, few live happily ever after. The usual pattern is that the doctor, if he lives long enough, does not give up his patients; the patients give up their doctor. . . . At the same time he must be aware of the let-down that will come when he is deprived of the daily interest and sense of importance that medical life so abundantly provides."

If doctors have interests outside of the field of medicine and if, through necessity or training, they are able to apply their talents as did Anton Chekhov in his brilliant literary accomplishments, it is always of great interest to learn just what started them off in the new fields of endeavor. Anton Chekhov loved to write letters to his friends. In fact, many of them, aware of his great literary talent, urged him to give up the practice of medicine and to devote all his time to literary work. Chekhov, however, realized that his medical background played an important role in making him an effective writer. He always liked to think that he had two professions at his command—medicine and literature. In a letter to a friend he stressed how important his medical background had been to him as a writer: "I have no doubt that the study of medicine has had an important influence on my literary work; it has considerably enlarged the sphere of my observation, has enriched me with knowledge the true value of which for me as a writer can only be understood by one who is himself a doctor. It has also had a guiding influence, and it is probably due to my close association with medicine that I have succeeded in avoiding many mistakes."

Among the factors that make some people turn away from intelligent physicians and place their trust in imposters is the delusion that physicians know everything and should effect cures immediately, like a magician. Again, some lay people hold that physicians should always use pleasant methods of treatment, procedures that are not at all times and in all cases possible. As patients are educated to obtain a reasonable understanding of disease, it has been the hope of most physicians that a better informed public would eventually grasp the essence of fake practices in medicine. Years ago Oliver Wendel Holmes wrote a letter to the New York Academy of Medicine about the intrusion of the quack into medical practice and the apparent willingness of some of the public to fall into his hands.

"The public is so ready, so eager to be deceived and the traders in deceptions are so willing, so hungry to deceive those who will listen to them that it needs a solid wall of resistance, a close united phalanx of men of recognized sense, knowledge and character to stand against them. . . . The Medical Profession will always have to fight against the claims of wrong-headed, and too often dishonest individuals and "schools" as they call themselves. . . . Long may it be before the wholesome barriers are weakened that separate the thoroughbred and truly scientific practitioner from the plausible pretender with his pseudopathy and his pseudotheraphy."

When a patient is sick and dispirited, a malignant disease is a very bitter pill to swallow. There have been several schools of thought as to whether patients should be told that they are suffering from an incurable disease. Times like these are also most difficult and trying for a physician. With respect to the problem, Dr. Johann Stieglitz, a highly respected German physician, wrote to a young medical friend in the early part of the 19th century:

"One can frequently hear people say that they do not fear death but are afraid of dying. . . . I have often thought it would be important to instruct physicians how to behave in cases of incurable disease, not so much to tell them what to do, but what not to do.

"I am often outraged when, in cases of large tumors, of carcinoma, of unquestionable protracted glaucoma and in innumerable instances, I see elaborate therapeutic plans being developed when no one can doubt that the disease is uncurable. . . . The patient often wishes to be told clearly whether he must be expected to die and whether death now be inevitable.

"Reasons are offered to show how important it would be to have this information and to prove with what fortitude and resignation he would be able to accept it. The physician may never take away all hope. . . . Man doesn't want others to inequivocally express even what is perfectly clear to him if it is of evil nature and affects him. He still wants to be able to believe that the contrary may be possible."

Many patients have been offered valuable medical advice in letters written to them by their doctors. Over a span of two and a half centuries, letters written by doctors have clearly reflected the existing status of medical practice. The complete evolution of medicine as known today can be traced through letters only because physicians enjoyed the personal pleasure of putting their experiences down on paper.

Letter sequences can be as exciting as sonnet sequences and a great deal more revealing. By reading letters written by physicians, it is possible to trace both the medical annals of the past and medical history in the making. In their letters, physicians frequently reveal sources of deep emotions, hidden up to that time from the public eye. Actually, it is only in a personal letter that the hidden springs of conduct may be revealed. A doctor will live in his letters as only a doctor likes to think he can live—a life of challenge and a life of critical self-examination.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Treatment of Chronic Congestive Heart Failure with Neohydrin for from Eight to 65 Months. G. C. Griffith, S. P. Dimitroff and M. C. Thorner. Ann. Int. Med. 45:7-13 (July) 1956 [Lancaster, Pa.].

Chlormerodrin (Neohydrin) has been described as one of the most efficient organomercurial diuretics available for oral administration. The authors evaluate its effectiveness in patients who received the drug daily for periods of up to 65 months. In view of the widespread belief that the principal toxic effects of organomercurial diuretics appear in the kidney, special attention was directed to this organ for evidences of injury. Twenty-three patients who had had chronic congestive heart failure for from 7 months to 18 years were studied. They were seen in the adult outpatient cardiac clinics of the Los Angeles County Hospital and also in private practice. More than half were over 60 years old. Arteriosclerotic heart disease was the most common entity, although a significant number had inactive rheumatic heart disease. Hypertension and cor pulmonale were also represented. The patients were given Neohydrin tablets, each containing the equivalent of 10 mg. of organic mercury. The daily dose varied from one to three tablets. Other indicated medication, such as digitalis preparations, low-sodium diet, and, occasionally, aminophylline, was included in the therapeutic regimen along with Neohydrin.

Observations on these patients confirmed the efficacy of the drug. Histological study of the kidneys was possible in one patient who initially had severe congestive heart failure with albuminuria and high nonprotein nitrogen values. He had received two tablets of Neohydrin daily for nine months. The congestive symptoms were controlled, and the renal abnormalities disappeared. He suddenly died of acute right heart failure. Postmortem examination showed normal kidneys except for passive congestion. There was no tubular damage. Thus albuminuria and high nonprotein nitrogen values are not necessarily a contraindication to treatment with this oral organomercurial diuretic. Neohydrin, however, is definitely contraindicated in the presence of primary renal disease. Active digestive tract disease and allergy are the other contraindications. The authors conclude that patients without primary renal disease but with albuminuria and high nonprotein nitrogen due to congestive circulatory changes can be adequately and safely treated with Neohydrin for long periods of time.

The Effectiveness of an Oral Vitamin K_1 in Controlling Excessive Hypoprothrombinemia During Anticoagulant Therapy. S. W. Cosgriff. Ann. Int. Med. 45:14-22 (July) 1956 [Lancaster, Pa.].

During the last year Vitamin K_1 in tablet form has become available for oral use. This drug, in doses of 2.5 to 20 mg., was administered to 75 patients in whom excessively elevated prothrombin-time values were produced by anticoagulant therapy. The coumarin or indandione drugs must be used in sufficient amounts to prolong the prothrombin time into the therapeutic range wherein an antithrombosing effect is produced but in which there is little risk of hemorrhagic complications, i. e., "safe but adequate" anticoagulation. At the laboratory of the author the therapeutic range for treatment of a patient with an acute thromboembolic problem is considered a prothrombin time between 22 and 35 seconds. It has been demonstrated that no further beneficial antithrombosing influence accrues when the prothrombin time rises above 35 seconds. Moreover, the majority of hemorrhagic complications occur in association with prothrombin-time values above this level. Consequently, it seems advisable to reduce a prothrombin time that has been elevated above 35 seconds as soon as possible to the safe therapeutic level, even though no bleeding has occurred. It has been customary at the author's clinic to administer water-soluble vitamin K parenterally or vitamin K_1 orally whenever the prothrombin time rises above 35 seconds.

In 63 of the 75 patients who were given vitamin K_1 in tablet form, the prothrombin time returned to the safe range (35 seconds or less) within 12 hours after oral administration and in all but 2 of the patients within 24 hours. The prothrombin time fell below the lower therapeutic level of adequate anticoagulation in 11 of the patients at 12 hours after the administration of vitamin K_1. Under such circumstances the administration of heparin ensured a continuing antithrombotic effect until subsequent doses of a coumarin or indandione agent again produced an adequate hypoprothrombinemia. Vitamin K_1 tablets for oral use provide an additional safeguard in coumarin and indandione therapy.

Postcardiotomy Syndrome in Patients with Rheumatic Heart Disease: Cortisone as a Prophylactic and Therapeutic Agent. D. T. Dresdale, C. B. Ripstein, S. V. Guzman and M. A. Greene. Am. J. Med. 21:57-74 (July) 1956 [New York].

In 33 (39%) of 84 patients with rheumatic heart disease who underwent cardiac surgery, a syndrome developed that was characterized by fever and, in descending order of frequency, chest pain of a pleuropericardial nature, congestive heart failure, pleural effusion, polyarthritis, arrhythmia, abdominal pain, and subcutaneous nodules. Laboratory evidence indicative of a nonspecific inflammatory process was frequently present. This increased the immediate postoperative morbidity and also that at a later date, at which time it usually incapacitated the patient. Death occurred in two patients; one died shortly after the intravenous administration of morphine, and the immediate cause of death was not clear. Autopsy did not reveal any evidence of rheumatic activity. Florid rheumatic myocarditis was revealed by autopsy in the other patient. Terms such as postcommissurotomy syndrome, reactivation of rheumatic fever following mitral commissurotomy, and postvalvulotomy syndrome have been used by other workers to describe this syndrome, but the authors prefer the designation "postcardiotomy syndrome in patients with rheumatic heart disease" because they observed the syndrome in a patient in whom only cardiotomy was performed and mitral valve surgery was omitted because of technical difficulties. It seems, therefore, that mitral commissurotomy is not necessary for the development of the syndrome. It is suggested that the postcardiotomy syndrome occurs in patients with rheumatic heart disease because of trauma to the heart or pericardium, which was the site of rehumatic activity at some time in the past.

For the purpose of studying the prophylactic use of cortisone postoperatively, the 84 patients were divided into two groups. Fifty-eight patients received cortisone within the first two postoperative days and were maintained on cortisone for from three to eight weeks thereafter. Doses of cortisone ranged from 150 to 300 mg. daily for the first two weeks and from 75 to 150 mg. for the next one to six weeks. The remaining 26 patients were not given cortisone postoperatively and served as controls. Cortisone had a definitely suppressive effect on the postcardiotomy syndrome. Eight (31%) of the 26 patients who did not receive cortisone prophylactically during the immediate postoperative period had the postcardiotomy syndrome during the initial three to eight weeks after the surgical intervention. In only 4 (7%) of the 58 patients who received cortisone prophylactically did the syndrome develop during a similar period while they were taking cortisone. The incidence of the postcardiotomy syndrome, however, was similar in both groups (8 [31%] of the 26 patients, and 17 [29%] of the 58 patients) after the initial postoperative

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

period of from three to eight weeks, when cortisone was withdrawn in the 58 patients. The immediate postoperative course of patients who received cortisone prophylactically was less stormy than that of those who did not. As a therapeutic agent, cortisone was superior to salicylates, aminopyrine, and antibiotics, none of which had a favorable effect on the clinical manifestations of the postcardiotomy syndrome. Cortisone in doses varying from 50 to 300 mg. daily, depending on the individual patient, caused a dramatic remission of symptoms and fever in the postcardiotomy syndrome. Because of the decreased immediate postoperative morbidity when cortisone was given prophylatically, and because corticotropin (ACTH) had an effect similar to that of cortisone on the symptoms of the postcardiotomy syndrome, the authors recommend that corticotropin (ACTH) be given prophylactically for two days preoperatively and for 8 or 10 days postoperatively to patients with rheumatic heart disease who are undergoing mitral valvulotomy.

Early Diagnosis of Bronchial Carcinoma. H. W. Knipping, E. Liese and A. Schmutte. Munchen. med. Wchnschr. 98:937-941 (July 13) 1956 (In German) [Munich, Germany].

The authors, who reported in 1951 on early signs of bronchial cancer in 150 patients, present here observations on 180 additional patients. Early recognition is the crucial point in bronchial cancer, because long-term therapeutic results have remained unsatisfactory despite the great advances in thoracic surgery. A series of special examinations must be carried out whenever there is even the slightest suspicion of bronchial cancer. These examinations include bronchoscopy, bronchography, cytological tests, and exploratory thoracotomy. However, suspicious signs are frequent in persons of certain age groups, and those who have them often regard them as trifling and refuse to submit to the rather exhausting examinations; at any rate, they are not inclined to submit to them repeatedly, the less so since only a small proportion of those who exhibit the early suspicious signs actually have bronchial cancer. For this reason, methods are required that can be carried out without causing too much inconvenience, so that the patient will submit to them repeatedly. In patients in whom bronchial cancer seems highly probable and in whom a surgical intervention is planned, bronchoscopy and bronchography should always be employed.

The authors feel that the most important method of preliminary examination is body-section roentgenography (tomography), particularly with the improvements they have introduced. The newest form of this body-section roentgenography is simultaneous multilayer tomography, which is explained with the aid of a diagram. This improved method can now be employed for routine examinations. Other diagnostic methods are bronchography with the aid of either radioactive iodine-alkyl or with radioactive xenon. These methods have proved useful in routine clinical work. Another important development in the early diagnosis of bronchial carcinoma is bronchography on the basis of the visualization of the distribution of radioactive xenon in the blood vessels and air passages. This method also enabled the authors to accomplish a direct demonstration of the moving heart (in situ and in vivo) without the aid of the roentgen apparatus (angiocardiography with the aid of isotopes). They also describe further improvements and developments aimed at the development of isotope bronchography. The use of isotopes, particularly of radioactive xenon, as employed by the authors in the diagnosis of cardiac and pulmonary disorders involves no inconveniences for the patients.

The Early Diagnosis and Natural History of Chronic Lymphatic Leukemia. C. Hougie. Ann. Int. Med. 45:39-55 (July) 1956 [Lancaster, Pa.]

Chronic lymphatic leukemia may run a long and practically asymptomatic course. The classic picture of splenomegaly, lymphadenopathy, anemia, and a very high leukocyte count is probably only a late phase in its natural history. The nine patients with chronic lymphatic leukemia described here were all first seen with presenting symptoms not attributable to leukemia and are of interest because of the light they throw on the natural history of the disease. Three of these patients died from causes unrelated to the leukemia shortly after the diagnosis of chronic lymphatic leukemia was established. Autopsies were performed on two of these. The lymph nodes in both patients showed no histological changes suggestive of leukemia, although well-marked lymphocytic infiltration of the portal tracts of the livers and extensive lymphocytic infiltration of the bone marrows were present. The spleen was not enlarged and showed no abnormal histological changes apart from congestion. Lymph node biopsy was performed at a relatively early stage of the disease in three of the remaining patients; these nodes showed no leukemic changes, while a splenic biopsy performed in one of the patients showed no leukemic changes. Lymph node biopsy is apparently of no value in the diagnosis of early chronic lymphatic leukemia. The leukocyte counts were below 45,000 per cubic millimeter in all but one of these patients. From other early cases described in the literature it appears that the leukocyte count usually remains low for several years and that anemia and thrombocytopenia are late manifestations of chronic lymphatic leukemia.

It is postulated that there are no signs or symptoms in the first stages of chronic lymphatic leukemia and that this "silent" phase of the disease lasts many years. It is succeeded by a phase, also of many years' duration, in which there are signs of the disease but no symptoms. The classic picture of the disease, with anemia, gross splenomegaly, lymphadenopathy, thrombocytopenia, and a very high white cell count, is considered to be only the terminal phase of a disease that usually runs a course lasting from 10 to 20 years.

Which Nodular Goiters Should Be Removed? M. Perlmutter and S. L. Slater. New England J. Med. 255:65-71 (July 12) 1956 [Boston].

The authors present a physiological plan for the diagnosis and treatment of nodular goiter. A review of the literature indicates that clinically palpable thyroid nodules are present in from 4 to 12% of the population of the United States. The incidence of cancer in unselected nodular goiters may be as high as 2 to 5%; in surgically treated multinodular goiter it is 3 to 10% and in uninodular goiter 9 to 33%. Most evidence indicates that benign thyroid nodules rarely undergo malignant transformation, and therefore surgical therapy as a prophylaxis against carcinoma is not indicated. Excisional therapy is indicated for nodules that are considered likely to be carcinomatous. Evaluation of thyroid nodules for malignancy or benigancy is performed on patients of the endocrine clinic of the Maimonides Hospital who have nodules that are clinically benign by means of laboratory determination of the total 24-hour uptake of radioactive iodine (I^{131}) by the thyroid gland. In patients with uninodular goiters (and those with masses restricted to one lobe), directional counts are made over the various parts of the gland, and the uptake over the nodular area is compared with that over the presumably normal parts of the gland. By definition, a "hot" (very probably benign) nodule is one that concentrates at least 125% as much I^{131} as the non-nodular portion of the gland. A nodule that concentrates less than 125% is considered "cold" (possibly malignant). In a multinodular gland with predominant nodules, directional counting is also done. Whereas 23% of the physiologically hypoactive nodules have been found to be malignant, the hyperactive nodules are uniformly benign. These nodules may successfully be treated medically.

The Prognosis of Patients with Intermittent Claudication. W. B Spaulding. Canad. M. A. J. 75:105-111 (July 15) 1956 [Toronto, Canada].

One hundred one men and seven women with intermittent claudication were studied in an attempt to learn what facts are of aid in making a prognosis concerning the patient's life as well as the affected extremities. Thirteen patients died within three years of the onset of the disease and 22 died within five years, but not all the patients were followed up for this length of time. Patients in whom the onset of the disease occurred early in life lived longer, on the average, than patients with a later onset. Normotensive patients had a better prognosis regarding life than those with hypertension. The group with unilateral claudication had a somewhat lower mortality rate than the group with pain in both lower extremities. Manifestations of cardiovascular disease were common in the patients during their lifetime, and atherosclerosis played a striking role in causing death. The incidence of cardiovascular disease was higher in patients with hypertension than in normotensive patients. Amputations were performed in 27 patients (25%). The first amputation was usually carried out within five years of the onset of intermittent claudication. Amputation was performed more often in patients with unilateral claudication than in those with bilateral claudication, but it was required less frequently in those with hypertension than in those with normal blood pressure because ischemic complications occurred less frequently in hypertensive than in normotensive legs.

Portal Hypertension Due to Chronic Occlusion of the Extrahepatic Portion of the Portal Vein: Its Relation to Ascites. A. H. Baggenstoss and E. E. Wollaeger. Am. J. Med. 21:16-25 (July) 1956 [New York].

From 215 autopsy patients with the anatomic diagnosis of occlusion of the portal vein the authors excluded all those with ascites in whom any coexistent lesion, such as concomitant cirrhosis of the liver, peritoneal carcinomatosis, chronic peritonitis, renal disease, congestive heart failure, obstruction of hepatic veins, Meigs' syndrome, myxedema, or obstruction of the inferior vena cava above the liver, which might by itself have been responsible for ascites, was found. This method of selection uncovered 15 cases of ancient thrombosis of the portal vein uncomplicated by any other condition that might cause ascites. In 10 of these cases no ascites was present; in 5 ascites was present and was of long standing. In addition to the pathological findings, the clinical findings and the course of the disease were studied in these 15 cases. In the group with portal obstruction without ascites there were five men and five women and their average age was 30 years. In the group of portal obstruction with ascites there were two men and three women and their average age was 45 years. Clinical and pathological evidence of portal hypertension was found in all 15 cases. Attempts to produce ascites in experimental animals by obstruction of the portal vein alone have for the most part been unsuccessful. Contrary to the results of these experiments, the authors' observations in five cases of chronic occlusion of the portal vein in which ascites could be attributed solely to this lesion emphasize the role of portal hypertension *per se* as an important contributing factor in the pathogenesis of ascites, even in the absence of hypertension of the intrahepatic portal system.

Comparison of the two groups of patients, those in whom ascites was present and those in whom it was absent, revealed that in the group without ascites the mean age was lower, the occurrence of better-developed accessory portal veins (hepatopetal circulation) was more frequent, and the degrees of enlargement of the spleen and of atrophy of the liver were less. Although no great significance can be ascribed to these differences because of the small number of cases in the two groups, these findings suggest that inadequate development of the hepatopetal collateral circulation may be a determining factor in the development of ascites in some cases of chronic occlusion of the portal vein.

Treatment of Addison's Disease. K. Emerson Jr. A.M.A. Arch. Int. Med. 98:100-105 (July) 1956 [Chicago].

When the diagnosis of adrenal insufficiency is made in a patient who is critically ill with the vascular collapse characteristic of an Addisonian crisis, a continuous intravenous infusion of from 2,000 to 3,000 ml. of 5% dextrose in isotonic sodium chloride solution containing 100 mg. of dihydrocorticosterone per liter should be started at once. The total volume of fluid must depend on the degree of shock and dehydration and the state of the cardiovascular system. The amount of hormone given should never be less than 200 mg. in the first 24 hours. Intravenous therapy should usually be continuous during the first 24 hours, because the patient may relapse into shock within 4 to 6 hours after its discontinuance unless he is supported by oral or intramuscular administration of hormone. Oral therapy is preferable to intramuscular because absorption is faster by the oral route and higher blood levels are obtained. Another 1,000 to 2,000 ml. of 5% dextrose in saline containing a total of 100 mg. of dihydrocorticosterone should be given on the second day over an 8-to-12-hour period. Frequent feedings with a bland high-carbohydrate diet may be started unless contraindicated by the condition precipitating the Addisonian crisis, such as a surgical operation. At least six hours before the end of this infusion, oral therapy with 25 mg. of cortisone every six hours should be begun. Most patients, by the third day, will be able to consume a normal diet and be maintained on cortisone given orally in doses of 25 mg. every six hours. This dose can be reduced subsequently by 25 mg. each day to the final maintenance level of 12.5 mg. twice daily by the end of a week.

When the diagnosis of Addison's disease has been established by the appropriate diagnostic procedures in a patient in whom the onset of symptoms has been gradual and who is not critically ill, oral therapy may be started at once according to the following regimen: 25 mg. of cortisone or 20 mg. of hydrocortisone is given on arising and again after 6 to 12 hours for one week or until distinct improvement in strength, appetite, and sense of well-being is observed. The dose is then reduced to 12.5 mg. of cortisone or 10 mg. of hydrocortisone given twice daily. The introduction of fludrocortisone, a potent hormone capable of supplying adequate salt retention in doses varying from 0.1 to 0.2 mg. per day, has simplified the management of patients with Addison's disease. Although it is necessary to continue the use of cortisone or hydrocortisone in combination with the fluorine-containing compound, it is becoming apparent that in some cases adequate maintenance can be achieved with only one-half of the previously indicated quantity of the glucocorticoids, namely, 12.5 mg. of cortisone or 10 mg. of hydrocortisone once daily. In a certain proportion of patients, especially those with relatively long-standing adrenal insufficiency, a period of several months may elapse before the full beneficial effect of replacement therapy will become evident. Eventually, however, by the proper adjustment of dosage, the patients with Addison's disease can be restored to normal health and activity.

Cortisone Test in Adrenal Hyperplasia and Adrenal Tumor. S. Wais. Medicina 16:1-10 (Feb.) 1956 (In Spanish) [Buenos Aires, Argentina].

The cortisone test for differentiating adrenal hyperplasia from adrenal tumor was performed in eight women ranging in age from 17 to 46 years. The group included three patients with bilateral adrenal hyperplasia, three with Cushing's syndrome, and two normal women. The Cushing's syndrome was due to bilateral adrenal hyperplasia in one patient and to unilateral adrenal tumor (adenoma and carcinoma respectively) in two patients. The test was made by Jailer's technique, which involves determination of the urinary 17-ketosteroids before and during administration of cortisone intramuscularly in daily doses of 200 mg. for three or four consecutive days up to a total of 600 or 800 mg. The urinary 17-ketosteroids greatly diminished by the end of the treatment in all four patients with bilateral adrenal hyperplasia, whereas the figures did not change after the treatment in the two patients with adrenal tumors. In the patient with carcinoma the urinary 17-ketosteroids increased during the administration of the hormone. In the two normal women, the urinary 17-ketosteroids diminished after administration of the hormone. The test is reliable for differentiating adrenal hyperplasia from adrenal tumor.

Smallpox in France: Recent Epidemiological Data. R. Crosnier. Semaine hôp. Paris 32:2198-2203 (June 22) 1956 (In French) [Paris, France].

One of the epidemics of smallpox in France during the period 1954-1955 occurred in the Morbihan department. There were 73 cases and 16 deaths. Special reference is made to the pulmonary forms presenting noninfectious labile infiltrate and to the pure febrile forms. Mass inoculation has occasioned skin conditions similar to those encountered during the epidemic at Marseilles in 1952. There is a close relation between vaccinal ectodermotrope virus and other equally ectodermic viruses. If dermatosis appears, it will occur generally between the 8th and the 13th day at the time of the maturity or at the beginning of the decline of the vaccinal lesion. After 15 days the complication will not appear.

The increasing role of allergy is discussed. Jennerian vaccination can reveal allergic processes that are homologous or foreign, unsuspected or latent, and confer on certain substances an accidental skin tropism in making them true reactogens. Their clinical consequences are frequently dependent on the character and degree of the vaccinal reaction. Whatever the criticism, Jennerian vaccination never proved ineffective in the contaminated area. Antivariolic vaccination has been regarded as a factor in the genesis of acute coronary thrombosis (eight cases with five deaths between the 7th and the 14th day). Contraindications to antismallpox vaccination are very limited, although some of them are absolute and permanent, for example, leukemias and diabetic states. In many circumstances allergy in a large and general sense plays an undeniable part in contraindication. In addition, although observed clinical conditions have until now seemed to result only from the infectious disease process, at present the allergic phenomenon must also be considered in the course of the development of certain smallpoxes. A late vaccination that is given after smallpox contagion and is therefore not inhibitive of the disease may produce allergic phenomena in certain cases. These phenomena should be investigated and dissociated from the true disease state. Contraindications must not be carelessly multiplied. There are certain cases where precautions and preventive measures are necessary with regard to Jennerian vaccination. However, in spite of possible but rare untoward side-effects or late effects, Jennerian vaccination remains indisputably the one irreplaceable and efficient prophylactic weapon against smallpox. Performance of mass vaccinations and revaccinations should be carried out without delay, not only locally but also in surrounding areas, in the event of an outbreak. Every certain or possible contact demands immediate vaccination.

Clinical Diseases of Adults Associated with Sporadic Infections by APC Viruses. E. Jawetz, L. Hanna, S. J. Kimura and P. Thygeson. A.M.A. Arch. Int. Med. 98: 71-79 (July) 1956 [Chicago].

Adenoidal-pharyngeal-conjunctival (APC) viruses are widely accepted at present as important causative agents of epidemic respiratory disease in military recruits and in children. An attempt was made by the authors to throw light on the role of these pathogenic agents in the causation of sporadic illness in adults. Five cases are described in men between the ages of 26 and 50 years, illustrating infection with adenoidal-pharyngeal-conjunctival viruses of types 2, 3, 6, 7, and 8. The illnesses ranged from simple mononuclear conjunctivitis without fever or respiratory symptoms to a severe influenza-like systemic disease, necessitating prolonged hospitalization. Types 2, 3, 6, and 8 of the APC viruses were isolated from the eyes in 9 of 22 patients whose clinical picture strongly suggested causation by these pathogenic agents. Involvement of the eye was observed by the authors in most of the proved sporadic APC virus infections in adults. In some the eye was the only site of manifest viral activity; in others it was associated with systemic or respiratory symptoms. The constancy of eye involvement suggests the role of the eye as a probable portal of entry and a site of major manifestations of APC virus infection.

The Use of Corticosteroids in Combination with Isonicotinic Acid Hydrazide in the Treatment of Advanced Bilateral Progressive Cavitary Pulmonary Tuberculosis. A. E. Handley. South African M. J. 30:605-606 (June 30) 1956 [Cape Town].

This is a preliminary report on a three months' trial of prednisone (Meticorten) and isoniazid (isonicotinic acid hydrazide) in the treatment of 23 Bantu females varying in age from 12 to 45 years. All had bilateral, advanced, progressive pulmonary tuberculosis with cavitation and with gross secondary pulmonary sepsis; they had had at least six months' hospital treatment (some had had previous admissions dating back to 5 or 6 years); their conditions were deteriorating under routine treatment; they were gravely ill with prognoses varying from poor to extremely bad; and they were obviously unsuitable for any form of operative procedure. Isoniazid was given in daily doses of 15 mg. per kilogram of body weight, as the only antituberculous drug. Antibiotics and sulfonamides were given in accordance with the response of secondary organisms cultured from the sputums. Complications such as amebiasis were treated as indicated at weekly examinations. The hospital diet was supplemented with extra protein in the form of a broth of protein hydrolysate, vitamin-B complex concentrate, and vitamins C and D. Hemopoietic substances and blood transfusions were given as indicated by blood investigations. Up to this point, treatment consisted of what might have been given under routine hospital procedure.

Prednisone (Meticorten) was given in daily quantities of 15 mg., subdivided in three doses, regardless of the weight of the patient. At the end of three months this dose was gradually reduced, while corticotropin was administered in increasing dosage as an adrenocortical stimulant. No patient died during this therapeutic trial, although a fatal outcome would have been anticipated in the majority of cases of this type. All patients exhibited marked clinical improvement. All but one showed satisfactory weight gains. On independent radiological assessment no patient showed further deterioration and five actually showed slight improvement; however, tubercle bacilli were always present in the sputum.

Oral Treatment of Diabetes Mellitus with Invenol: Indications and Contraindications; Insulin-Resistant and Invenol-Resistant Diabetes: Factors Causing a Renal Effect. J. Bloch and A. Lenhardt. Wien. med. Wchnschr. 106:594-598 (July 7) 1956 (In German) [Vienna, Austria].

Highly satisfactory results were obtained with Invenol, a proprietary preparation of carbutamide, in 400 patients with diabetes mellitus. Treatment was started with a daily dose of 4 or 3 gm. After a few days the dose of the drug was reduced to 2, 1, or 0.5 gm., and that was used as the maintenance dose. Undesirable side-effects consisted of anorexia, stomach-ache, and heart-burn in 2 patients and of a toxic morbilliform or urticarious rash in 10. The rash subsided within a few days after withdrawal of the drug. The drug did not cause any damage to the liver, kidneys, nervous system, or morphological elements of the blood, particularly the leukocytes.

Carbutamide therapy is indicated in patients with diabetes mellitus who are sthenic in type, with a tendency to obesity, and of middle or advanced age, i. e., in patients with "diabetes with insulin resistance." Carbutamide therapy is contraindicated in hyposthenic patients with "insulin-deficiency diabetes," i. e., diabetes with resistance to carbutamide. It is contraindicated in children and adolescents with diabetes mellitus, in pregnant women at least during the last months of pregnancy, in patients with intercurrent disease, and in those with acidosis. Surgical intervention or the preoperative period are contraindications to carbutamide therapy. From one-third to one-half of the patients with diabetes mellitus may be treated successfully with carbutamide. Insulin remains fully effective after the withdrawal of carbutamide. The positive effect of carbutamide can be reproduced at any time. Carbutamide is not a substitute for insulin but it either stimulates the beta cells or increases, by enzymatic action, the effect of the endogenously produced insulin. Two observations were made that suggest that the mechanism of action of carbutamide differs from that of insulin. Old insulin frequently causes a rapid decrease in the excreted amount of urine, whereas carbutamide causes polyuria. Insulin causes a simultaneous decrease in the blood sugar level and in the amount of sugar excreted in the urine. Glycemia may be restored to normal by carbutamide, but increased glycosuria may persist. It is suggested that carbutamide exerts an influence on the tubular reabsorption of water and sodium and perhaps also on that of sugar.

The Problem of Chronic Liver Disease in Young Women. A. G. Bearn, H. G. Kunkel and R. J. Slater. Am. J. Med. 21:3-15 (July) 1956 [New York].

This report deals with 26 young adult patients with cirrhosis of the liver whose symptoms and signs differed from those of patients with the more comon type of cirrhosis. The predominance of women in this group was striking, since only 3 of the 26 patients were men. The average age of the patients at the onset of the disease was 15 years. Delayed menstruation or amenorrhea before or coincident with the onset of symptoms related to liver disease occurred in 15 of the 23 women. In four patients acne, hirsutism, pigmented striae, obesity, and moon facies were also noted before the recognition of liver disease. In some patients transient rashes similar to those seen in erythema multiforme were observed early in the course of the disease. The well-nourished and relatively healthy appearance of these patients belied the seriousness of their disease. As the disease progressed, the classic signs of hepatic cirrhosis became increasingly apparent. The spleen was usually considerably enlarged and was frequently palpable at the earliest recognizable stage of the disease. Spider angiomas and liver palms developed in most of the patients. Clinical ascites, in sharp contrast to the findings in many patients with Laennec's cirrhosis, was relatively uncommon in these patients in the early stages of the disease. In 10 patients obscure febrile episodes sometimes associated with respiratory or cardiac symptoms occurred at some time in the course of the disease. Numerous blood cultures were performed in an attempt to isolate a causative agent, but in none of the patients was a positive blood culture obtained. Eleven patients (42%) complained of joint pains of varying degree. These symptoms usually occurred early in the course of the illness and in some patients were accompanied by an acute non bacterial febrile attack associated with a temporary exacerbation of the liver disease.

Twelve patients died as a direct result of the disease process, of either esophageal hemorrhage or progressive hepatic coma. The average duration of the disease in these patients was about seven years. The mean duration of the disease in those still living is five and a half years. Striking improvement followed the use of cortisone in some patients. Continued use of small doses of cortisone may be of some value but there is as yet no conclusive evidence that cortisone has modified the disease process or that it will alter the eventual outcome. Laboratory studies in the acute stages of the disease usually revealed an extremely high serum gamma globulin level and an increase in the plasma cells of the liver. The possibility that specific endocrine influences, present in young women, may modify the usual course of infectious hepatitis has been discussed. In most of the patients the causation of the disease process was uncertain.

SURGERY

Complications of First Rib Fracture, Including One Case Each of Tracheoesophageal Fistula and Aortic Arch Aneurysm. T. W. Holmes Jr. and R. E. Netterville. J. Thoracic Surg. 32:74-91 (July) 1956 [St. Louis].

Seventeen (10%) of 170 patients who were hospitalized between Jan. 1, 1947, and Dec. 31, 1954, with a diagnosis of fractured ribs, had fractures of one or both first ribs, isolated or in addition to other rib fractures. All of these fractures, with the exception of those in one patient, were produced by closed chest trauma, in most cases by sudden deceleration in an automobile accident in which the chest sharply struck the steering wheel. Severe mediastinal complications occurred in 2 of the 17 patients with first-rib fracture; in one patient an esophageal diverticulum with tracheoesophageal fistula was diagnosed six months after the injury, and in the other patient a fusiform aneurysm of the aortic arch was diagnosed more than two years after the injury. The tracheoesophageal fistula was successfully repaired by direct division and suture. The aneurysm, which was entirely asymptomatic, was covered with reactive polyethylene and responded well to this conservative surgical treatment. Other complications in the patients with first-rib fracture included injury to the brachial plexus and stellate ganglion and an unusual obstruction of both subclavian veins from the pressure of excessive callus about the healing bilateral fractures. Remaining complications in this group of patients were the common sequelae of pleural puncture by the rib fragments.

As a result of their experience and a survey of the world literature concerning first-rib fractures, traumatic tracheoesophageal fistula, and traumatic aneurysm, the authors state that trauma sufficient to produce fracture of a first rib by indirect force is capable of causing injury to mediastinal soft parts. Lesions of lesser magnitude than complete disruption of the tracheobronchial tree or great vessels may be considerably delayed in development or in producing diagnostic symptoms or signs. In patients with closed thoracic injuries, especially those produced by high-speed automotive accidents, one must search carefully for evidence of first-rib fracture, which may be easily overlooked before callus formation begins. Patients with such fractures without early manifestations of mediastinal lesions must be thoroughly examined at frequent intervals for at least two years after the injury. Each examination should include a roentgenogram of the chest. Widening of the superior mediastinal shadow in the vicinity of the aortic arch following chest injury should be considered a sign of possible incomplete rupture of the aorta or other great vessel from which an aneurysm may develop.

The Physiologic Effects of Fibrothorax and the Functional Results of Surgical Treatment. A. A. Siebens, C. F. Storey, M. M. Newman, and others. J. Thoracic Surg. 32:53-73 (July) 1956 [St. Louis].

Eleven patients, 10 of whom were men less than 35 years old, required pleural decortication of either a tuberculous or a nontuberculous pleural peel. The right side of the chest was the site of the disorder in five patients and the left side in six. The duration of the disorder varied from 2 months to 13 years. The patients were evaluated from a respiratory point of view both before and after the operation. The tests performed pertained to unilateral and bilateral ventilation and total lung volumes, intrapulmonary mixing of respiratory gases, ventilation-perfusion relationships, and relative dimensions of the diffusing surface (maximum diffusing capacity).

The preoperative deficit usually consisted of impaired ventilation, diminished lung volumes, and a reduction in the dimensions of the alveolar capillary bed. Defects in the mixing of gases within the lung and in the relationship between ventilation and perfusion were uncommon. Pleural decortication was usually followed by improved ventilation, increased lung volumes, and restoration of alveolar-capillary units. Among the most constant effects of the operation in these patients was an increase in residual volume, a change that could be attributed to the removal of a noncommunicating intrathoracic mass and to the release of retracted parietes. Associated roentgenographic findings were the elimination of density between the lungs and thoracic wall and the widening of the intercostal spaces, which was frequently seen postoperatively. This increase in residual volume, either absolute or relative to the total lung capacity, should not be identified with "overdistention" and construed as detrimental to function. The functional residual capacity was also commonly augmented by the operation, and the reasons for this increase paralleled those cited for the changes in residual volume. Comparison of tuberculous and nontuberculous groups indicated no striking differences with respect to the patients' postoperative respiratory status. Duration of disease, parenchymal involvement, postoperative complications, and the degree of preoperative functional impairment were factors contributing to the extent of recovery. Protracted disease did not preclude improvement.

Despite postoperative improvement, no patient was fully restored to normal by operation. The period of convalescence before the postoperative study was three months or less in most of the patients. This short postoperative interval accounted in part for the limited recovery. No gross deficit occurred as the direct result of surgery. Consistently with the essentially mechanical nature of the impairment imposed on the lungs by pleural envelopment, the physiological abnormalities produced were reversible to varying degrees by surgical removal of the confining structures.

Surgery of Eventration of the Diaphragm. E. F. Chin and R. B. Lynn. J. Thoracic Surg. 32:6-14 (July) 1956 [St. Louis].

Eventration of the diaphragm, a congenital, abnormally high position of the intact diaphragm, was observed in 18 male and 19 female patients between the ages of 13 and 72 years. Five of the 38 patients were treated successfully by surgery. Four of these patients had symptoms, including epigastric pain, flatulence, belching, and severe melena, that required surgical treatment. The fifth patient, a 13-year-old boy, had no symptoms, but it was felt that the extensive defect warranted repair. A careful dissection around the chest wall and the pericardium is imperative, mobilizing the muscular portion of the diaphragm to its fullest extent. This muscular portion is often well hidden and appears almost to be covered by its own membrane. Once it is fully mobilized, the affected portion of the diaphragm can be resected and muscle-to-muscle suture performed. In none of the patients was it difficult to obtain muscular apposition, and postoperative roentgenologic examination showed an intact diaphragm with limited but normal movement on respiration. No reinforcement, such as tantalum mesh or fascia lata grafts, was necessary.

The Nonoperative Treatment of Traumatic Chylothorax. J. V. Maloney Jr. and F. C. Spencer. Surgery 40:121-128 (July) 1956 [St. Louis].

The increasing number and scope of intrathoracic surgical procedures has been accompanied by a rise in the incidence of chylothorax, and the mortality rate of this surgical complication has been found to be as high as 50%, although this rate has shown a progressive decrease during the last 10 years. The trend toward the early surgical treatment of chylothorax by ligation of the thoracic duct is now well established. The purpose of the present discussion is to temper the current enthusiasm for early operative intervention. Thirteen patients with chylothorax were treated without morbidity or mortality. Eleven of these responded to the simple expedient of multiple thoracenteses. Two patients were subjected to a second operation, but on the basis of their present knowledge the authors feel that in these patients closed catheter drainage could have been tried before operation. They are convinced that persistence with nonoperative treatment by thoracenteses or closed catheter drainage will be rewarded with a high degree of success.

Esophageal Dystonia. R. H. Schug. West. J. Surg. 64:391-393 (July) 1956 [Portland, Ore.].

Esophageal dystonia is the author's choice of the four terms that have been applied to a noninflammatory, non-neoplastic constriction of the lower esophagus. The other three terms are cardiospasm, achalasia, or megaesophagus, the latter term referring to the enlarged esophagus proximal to the constriction. The condition is due to a localized defect in autonomic innervation. Several medical and surgical treatments have given poor long-term results. The author describes a surgical method that neither produces a sliding hernia nor damages the diaphragmatic crura. A transthoracic approach is used, and, if a sling type of hernia exists, it can be visualized and repaired.

After the chest is opened through the bed of the eighth rib, the phrenic nerve is anesthetized and a radial incision is made in the dome of the diaphragm at a distance from the esophageal hiatus, care being taken not to interfere with the sphincter action of this hiatus. Through the opening in the diaphragm a high gastrotomy is carried out, and the index finger is inserted through it into the esophagus. With the finger in this position and under direct vision, the pleura over the esophagus is incised and an anterior, extramucosal myotomy is carried out. The incision is made long enough to open the entire constricted area, but does not extend more than 2 cm. beyond it at either end. The esophagus is not dissected from its bed and is disturbed as little as possible. After the myotomy, a Levin tube previously introduced into the dilated portion of the esophagus is threaded through into the stomach. The tube may be removed and fluids and food may be given as early as 48 hours after the operation. Two illustrative case histories are presented. An extramucosal esophageal myotomy is a safe and simple method that will produce cure. The procedure minimizes the possibility of postoperative regurgitation. Severe esophageal dystonia requires prompt surgical treatment.

Pulmonary Resection as an Adjunct in the Treatment of Pulmonary Tuberculosis. J. W. Gale, H. Dickie, J. Rankin and A. R. Curreri. Am. Rev. Tuberc. 74:29-41 (July) 1956 [New York].

The authors present observations on 1,165 patients in whom resection was carried out as an adjunct to the treatment of pulmonary tuberculosis during the 10-year period ending in May, 1954. There was a sharp increase in resections after 1950, because under the influence of long-term chemotherapy surgical resection became possible at a better than reasonable cost in terms of operative mortality and postoperative complications. The general goal of drug therapy was the attainment of maximal resolution of reversible disease and the closure or eradication of open lesions. Persistent necrotic lesions, which often harbored viable bacilli, were then resected. In this way it was possible to restrict the extent of resections and preserve pulmonary tissue. The optimal time for surgical intervention varied considerably, depending on the extent and severity of the disease, the age of the patient, and the presence of complications such as endobronchitis. On the average, a patient received antimicrobial therapy for from 9 to 15 months prior to resection. Bronchoscopy was performed several days before resection in nearly all patients. If any evidence of endobronchitis was present, surgical intervention was delayed. In some instances the addition of oxytetracycline to the antimicrobial therapy cleared the minor endobronchitis. The greatest therapeutic challenge, however, was the patient with persistent cavitation and endobronchitis whose tubercle bacilli had lost susceptibility to streptomycin and isoniazid. Pulmonary resection in these patients was hazardous because of the greatly increased risk of bronchopleural fistula. Prevention of the development of resistance to drugs is of primary importance in these patients.

At present the tendency is to resect a cavitary lesion at an earlier period rather than to wait for reversal of infectiousness and cavitary closure to occur, if this has not been accomplished after a four-to-six-month period of treatment. If either streptomycin or isoniazid has not been used, it is added to the drug regimen. If surgery is regarded as feasible, the resection is planned within the four-to-six-week interval after the addition of the streptomycin or the isoniazid. However, if, in spite of roentgenographic evidence of residual cavitation, the sputum no longer contains tubercle bacilli on microscopy or culture, the period of preoperative chemotherapy may be extended if the extent of removable pulmonary tissue can thus be significantly decreased. The authors were able to obtain information on 1,115 patients who were followed for from 1 to 10 years. The operative mortality was 3%. An additional 3% of the patients have died in the intervening years from various causes, including active pulmonary tuberculosis. Two per cent of the patients still have active tuberculosis, but 1,015 (91%) of the 1,115 who could be traced are clinically well and are classified as having inactive tuberculosis.

Evaluation of Vagotomy and Pyloroplasty in the Treatment of Duodenal Ulcer. H. E. Dorton. J. Kentucky M. A. 54:602-609 (July) 1956 [Louisville, Ky.].

Dorton reports on vagotomy combined with a drainage procedure in 151 patients with duodenal ulcer. Early in their use of vagotomy they found that symptoms of mechanical pyloric obstruction would sometimes develop and be troublesome. A drainage procedure was added in order to overcome this difficulty. Pyloroplasty was done, because it would allow confirmation of the diagnosis, removal of the scarred area, and restoration of the anatomy to a more natural state.

At operation the diagnosis is first confirmed by inspection of the region or, if necessary, by opening of the pylorus and of the first part of the duodenum. Then subphrenic vagotomy is carried out, great care being taken that no branches of the nerve are overlooked. A complete vagotomy is more readily carried out if the esophagus is drawn well down into the abdomen so that the two main trunks of the nerve are reached rather than the arborization further down. Then attention is given to the drainage problem. In all but five of the 151 patients it was possible to perform a pyloroplasty. The simplest type, that of Judd or Mikulicz, was used 125 times. It consists of a linear incision of the pyloroduodenal junction so that two fingers can be inserted into the duodenum and up into the stomach. The ulcerated area is trimmed away and the opening is closed transversely. A neat closure is almost always followed by a smooth convalescence and a good result. Rough handling or inversion of too much tissue is likely to interfere with drainage and jeopardize the result. When the ulcer is located on the posterior-superior or the posterior-inferior duodenal wall, the area is wedged out. The resulting V-shaped defect is closed side-to-side and the remainder of the closure is the same as for simple anterior-pyloroplasty. This has been used 14 times in this group. These simple procedures are inadequate when the duodenum is greatly distorted or the ulcer is deeply embedded in the pancreas. In these patients, the author cuts across the duodenum just distal to the area and across the pylorus just proximal to the sphincter and discards the intervening unhealthy tissue. The stomach is then joined to the open end of the duodenum in a simple end-to-end anastomosis as in the Billroth I operation. This procedure was used seven times in this series.

A short-loop posterior gastroenterostomy was necessary in five of the patients. There were two deaths in the 151 patients; satisfactory results were obtained in 91% of the cases. The average hospital stay after surgery was a little over eight days. The effect of the procedure on the patient's weight was very encouraging. The author concludes that vagotomy and pyloroplasty is a satisfactory method for treating nearly all types of complicated duodenal ulcer. Bleeding ulcer is amenable to the same treatment provided the ulcer is removed. The ability to eliminate side-effects appeared to be directly proportional to the ability to restore the pyloroduodenal outlet to as nearly normal size and contour as possible. A patient who has obtained a good result usually remains well.

Colon Polyps and Unexplained Rectal Bleeding. G. C. Tyler. West. J. Surg. 64:374-376 (July) 1956 [Portland, Ore.].

In the absence of an obvious carcinoma, bleeding from the rectum that is not explained by anorectal lesions is frequently due to polyps of the colon and their sequels. Approximately 10% of patients over the age of 40 have adenomas or polyps of the colon. Bleeding occurs when these lesions reach a diameter of about one-half inch, so that the passage of feces causes ulceration. The clue therefore is bleeding. Diagnostic routine involves, in the order named, rectal examination and sigmoidoscopy; barium enema; air-contrast barium enema; and exploration of the abdomen and colposcopy. Forty-one cases are renewed. The presence of a polyp was verified by laparotomy in all 41 patients. The author stresses the fact that if in the presence of bleeding from the rectum a lesion cannot be found by repeated sigmoidoscopy and if repeated x-ray studies are inconclusive, then laparotomy and direct sigmoidoscopic visualization of the colon are imperative. Operative mortality and morbidity are so low as to be almost never a contraindication to laparotomy.

The Ulcerogenic Tumor of the Pancreas. E. H. Ellison. Surgery 40:147-170 (July) 1956 [St. Louis].

Ellison is concerned with a new clinical entity consisting of a fulminating and frequently fatal peptic ulceration associated with a non-insulin-producing islet cell tumor of the pancreas. A review of the clinical records and autopsy protocols of all patients admitted to the Ohio State University Medical Center during the past 10 years with the diagnosis of peptic ulceration and/or pancreatic tumor disclosed five patients with this disorder. These five cases bring the total of reported "ulcerogenic tumors" of the pancreatic islets to 24. Although 19 of the 24 islet adenomas were malignant, the rate of growth was slow and peptic ulceration remained the predominant manifestation in nearly all of the patients. Only 11 of the 19 malignant tumors had spread beyond the confines of the pancreas.

This new clinical entity is characterized by excessive gastric secretion and rapidly progressive, atypically located ulcers recurring despite adequate medical or surgical therapy. The associated tumor remained unrecognized until autopsy in nine patients, who underwent 23 operations for 35 primary and recurrent marginal ulcerations and who died of ulcer with an average survival time of 17 months. The tumor was removed at operation in 11 patients with complicated ulcer disease, and of these, 5 are living. Three patients died of ulcer, and in each instance overlooked islet tumors were found in the pancreatic remnant. The remaining three patients succumbed to recurrent tumor. The average survival time in the six fatal cases was 6.6 years, which represents a considerable improvement over results obtained in the patients in whom the pancreatic tumor was overlooked. Furthermore, the improved results indicate the importance of the tumors in the pathogenesis of this invariably fatal ulcer disease.

Documented observations of the return of gastric secretions to normal levels after resection of a non-insulin-producing islet cell tumor of the pancreas in a patient with hypersecretion and recurrent marginal ulcerations suggest that a hormonal or chemical factor arising in the pancreatic tumor is capable of stimulating the gastric glands to secrete and may be the causative agent of the ulcer disease. Until such time as better methods of diagnosis are available, it seems reasonable to suggest that a careful search of the pancreas should be made in all patients operated on for peptic ulcer. This is particularly important in patients with atypically located primary ulcer or those operated on for recurrent marginal ulceration. The surgical attack should include removal of the tumor, combined with some standard ulcer procedure designed to protect the patient in the event of recurrent or residual tumor. Finally, the difficulties encountered in palpating a small pancreatic adenoma suggest that resection of the body and tail of the pancreas may be advisable before subjecting a patient to total gastrectomy as a final heroic method of controlling the acid factor.

Carcinoid (Argentaffin) Tumors of the Gastrointestinal Tract. W. G. Diffenbaugh and R. E. Anderson. A. M. A. Arch. Surg. 73:21-37 (July) 1956 [Chicago].

Diffenbaugh and Anderson review the records of all patients with carcinoid tumors found in the files of St. Luke's Hospital. Chicago. Langhans described a carcinoid tumor as early as 1867, although he did not recognize it as such. Lubarsch in 1882 first used the term "little carcinomas," and Oberndorfer designated these tumors as "carcinoids" in 1907. The term "argentaffin" was first applied to them by Gosset and Masson, who found that cells within these tumors took a silver stain. It is now generally accepted that carcinoid tumors arise from the Kulchitsky cells of the crypts of Lieberkühn of the gastrointestinal tract. Carcinoid tumors have been reported as occurring in the stomach, gallbladder, duodenum, small intestine, Meckel's diverticulum, appendix, ileocecal valve, cecum, colon, rectum, and in the gastrointestinal components of teratomas of the ovary. Nearly 75% of the 51 carcinoid tumors in the files of St. Luke's Hospital were appendiceal in location.

Grossly, carcinoid tumors are light yellow in color, probably because of their high lipoid content. They are usually antimesenteric and submucosal in location in the intestinal wall. The typical cell is a small epithelial cell with an oval or round nucleus that has a well-defined nuclear membrane and a fine stippling of chromatin. The cytoplasm is palely acidophilic, small in amount, vacuolated or granular. The cells are in columns, nests, coils, or masses. Tumor cells in the metastatic foci may look benign by the usual histological criteria of malignancy. Frequently the cells in the metastatic deposit may take on an entirely different histological arrangement from that seen in the primary tumor. The carcinoids of the small intestine may manifest themselves by an acute obstruction due to intussuception of a polypoid tumor. This obstructive feature, as well as various other aspects of carcinoids of the small intestine, such as their multiplicity and their association with liver metastases, are illustrated on the basis of case histories. Liver metastases from carcinoid tumors of the small intestine may be associated with cyanosis, peripheral vasomotor symptoms, pulmonic stenosis, and tricuspid regurgitation without septal defects. The vascular lesions are presumably secondary to the prolonged action of serotonin, secreted by the tumor tissue. That carcinoid tumors may be functioning neurocrine tumors related to pheochromocytomas has been suggested in several reports.

Carcinoid tumors may appear anywhere along the gastrointestinal tract from the stomach to the anus. Histologically, the appendiceal carcinoids show frequent invasion of the muscle and serosal layers of the appendix, even though evidence of lymph-node metastases is infrequent. This type of tumor, wherever located, is malignant. The incidence of metastases of these tumors in various areas of the gastrointestinal tract usually parallels the stage in time at which the tumor is detected.

Treatment of Arteriosclerotic Occlusive Disease in 101 Lower Extremities by Arterial Homografts. E. S. Crawford, O. Creech Jr., D. A. Cooley and M. E. De Bakey. South. M. J. 49:665-670 (July) 1956 [Birmingham, Ala.].

Results from the conventional surgical therapy of arterial insufficiency in the lower extremities (sympathectomy and amputation) have been disappointing. In spite of sympathectomy, approximately one-third of these extremities ultimately required amputation. Fortunately, many arteriosclerotic occlusive lesions are segmental in character and an unobstructed distal segment is often satisfactory for anastomosis, permitting effective treatment with restoration of circulation distally. This paper is concerned with the use of lyophilized arterial homografts in the treatment of 101 extremities with arteriosclerotic occlusive lesions located distal to the level of the aortic bifurcation. The primary objective of operation is to restore normal pulsatile blood flow into the distal arterial bed and simultaneously to minimize the tendency to recurrence of the occlusive process and to impose minimal risk on the existing circulation in the event of failure. When arterial homografts were first used by the authors, the short, discrete, occlusive segment was completely excised and replaced by a homograft sutured end-to-end to the host artery; this was done on 26 extremities. More recently, however, no attempt has been made to excise the involved vessel, the occluded segment being by-passed by an arterial homograft sutured end-to-side into the artery proximal and distal to the block, as suggested by Kunlin. Thus, in 75 cases the by-pass procedure was used.

Restoration of circulation distal to the occlusion, as determined by arteriography or by the presence of pulses, was accomplished in 92 of the 101 extremities treated. Among 12 patients with femoral occlusion treated by excision and end-to-end grafting there were 3 unsuccessful results, but the same procedure was performed on 14 patients with iliac obstruction without a failure. Failures followed the by-pass procedure in 3 of 29 patients with femoral occlusion and in 3 of 46 with iliac occlusion. In general, failure occurred in borderline cases in which the distal segment was sclerotic and out-flow from the graft was poor. It is estimated that amputation was prevented in 18 cases.

Thyroidectomy and the Recurrent Laryngeal Nerves. A. D. Roy, R. H. Gardiner and W. M. Niblock. Lancet 1:988-990 (June 23) 1956 [London, England].

To ascertain the frequency, cause, and results of damage to the recurrent nerves during operations on the thyroid, Roy and associates examined the records of 300 patients operated on for nonmalignant conditions of the thyroid. All 40 patients showing damage to the recurrent nerve were followed up for at least a year. In 22 patients the right recurrent nerve was damaged, in 17 the left nerve, and in one patient both nerves were damaged. Complete recovery resulted in 18 of the patients, in 6 of whom the initial lesion was partial, manifesting itself as sluggishness and weakness in adduction of the vocal cord. Only two of these patients noticed any change in their voices. In 11 patients there was initially complete paralysis of a cord in the paramedian position midway between adduction and abduction, and in one patient the paralysis was partial within six days of operation and complete a month later. Movement of the vocal cord was not restored in 22 of the patients, including the one with bilateral lesions.

As regards the cause of damage to the recurrent nerves, in 19 patients difficulties were met with at operation. Emphasis is placed on the danger to the nerves at a low level in the neck in the presence of lower-lobe adenomas and in retrosternal prolongations. The nerves are also highly vulnerable where they are crossed by, or mingle with, the branches of the inferior thyroid artery. No operative difficulty was noted, and yet one of the nerves was damaged in 21 of the 40 patients. In 14 of these recovery resulted; presumably, the nerve was either stretched or caught in a hemostat in these patients. The prognosis of damage to the recurrent nerve is good. The recovery rate is high, and in patients in whom the nerve does not heal, compensation by the other vocal cord is usually good and functional recovery rapid and often complete. An accurate estimate of the frequency or extent of damage to the recurrent laryngeal nerves can only be obtained if the vocal cords are examined both preoperatively and postoperatively.

Late Results of Resections for Tuberculosis of the Upper Lobe. E. Hoffman. Thorax 11:160-162 (June) 1956 [London, England].

Hoffman reviewed the results of 100 resections for pulmonary tuberculosis of the upper lobe from one to six years after operation. The radiological appearances, sputum-conversion rate, complications, respiratory function, and working capacity were investigated. Serious postoperative complications (bronchopleural fistula, spread of disease) occur mainly in the first 12 months after the operation. There were no deaths in the late follow-up period. The majority of patients showed no clinical evidence of impaired respiratory function, and a large number were able to return to a normal working life. Primary resection of upper lobes was occasionally followed by poor results. This was the case in patients with large apical cavities and bilateral fibrocaseous disease, particularly when disease had at some time been present in the lower parts of the lung. Thoracoplasty still remains the procedure of choice for these patients. The reason for the decline in the popularity of this operation in some centers is the respiratory inefficiency that follows an extensive thoracoplasty. With present-day chemotherapy, the removal of more than five ribs should rarely be necessary. In extensive unilateral disease where the volume of the residual lung would not be sufficient to fill the space, thoracoplasty should be done as well as resection. This may be done either as a combined procedure or with the thoracoplasty as a preliminary operation. Resection has proved to be a satisfactory operation (1) in residual caseous foci, (2) in chronic fibrocaseous disease of segmental or lobar distribution, particularly if some degree of atelectasis is present, and (3) when thoracoplasty has failed.

The Surgical Treatment of Esophageal Stricture. L. D. MacLean and O. H. Wangensteen. Surg. Gynec. & Obst. 103:5-14 (July) 1956 [Chicago].

Eighteen patients with esophageal stricture have been treated by a surgical procedure designed to decrease acid-peptic irritation of the lower esophagus. Fifteen of them underwent subtotal gastrectomy, and in three hiatal-hernia repair accompanied by a Heineke-Mikulicz pyloroplasty was performed. In all 18 patients, complete disappearance (13 patients) or substantial improvement (5 patients) in dysphagia occurred. The period of observation after operation ranged from 4 months to 16 years. Gastric resection was carried out in one patient with an extensive corrosive stricture of the esophagus, with but slight improvement. An accompanying gastric or duodenal ulcer was observed in six patients; both duodenal ulcer and hiatal hernia were present in seven patients; both duodenal ulcer and hiatal hernia in one patient; and in four patients no concomitant anatomic abnormality was detected. Reestablishment of a fairly normal esophagogram after gastric resection was observed in even the most deformed and strictured esophagi in the follow-up roentgenograms, which were taken over a period of months. The esophageal lumen size, estimated by the size of the dilator that traverses the strictured area, increased markedly in the immediate and early postoperative period. Preliminary microscopic studies suggest that the depth of the esophageal lesion in acid-peptic esophageal stricture involves primarily the superficial layers of the esophageal wall (mucosa and submucosa) as contrasted with the stricture that results from the ingestion of corrosive caustic agents, in which the entire esophageal wall becomes involved in the fibrotic process. Gastric-acid production frequently is elevated in patients with esophageal stricture. Esophageal resection with intrathoracic or cervical esophagogastrostomy is recommended for lye or concentrated acid stricture. Two patients who were incapacitated and without lasting benefit from dilations have been restored to full health after resection of the esophageal stricture.

Carcinoma Associated with Ulcerative Colitis. R. H. Thorlakson Surg. Gynec. & Obst. 103:41-50 (July) 1956 [Chicago].

Twelve cases of carcinoma of the colon and rectum found in 182 consecutive colectomies performed for ulcerative colitis at St. Mark's Hospital in London, England, were reported. Eight of the 12 cases were diagnosed as malignant before operation Carcinoma associated with ulcerative colitis occurred from 10 to 15 years earlier than in the general population. The incidence of carcinoma in patients affected by ulcerative colitis for 10 years or more was much higher than in patients of the same age and sex who had not had it. The policy of earlier colectomy adopted in recent years has improved the prognosis of patients with ulcerative colitis who develop malignant growths in the colon or rectum. The presence of adenomatous polyps might well be added to the criteria to hasten the decision for radical surgery before the onset of malignant change. "Stricture" areas in chronic cases should be closely watched because strictures may prove to be the earliest evidence of malignant change. A carcinoma could easily be mistaken for an inflammatory stricture, and it is frequently difficult to distinguish the two. Multiple carcinomas are frequently found in cases of malignant tumor associated with chronic ulcerative colitis. Contrary to reports that cancerous tumors associated with the disease are frequently atypical, the characteristics of carcinoma in this series tended to take on the general pattern of ordinary carcinoma of the rectum and colon. Malignant changes often appeared first in the quiescent stage of ulcerative colitis, when clinically the patient seemed to have improved.

Analysis of Five Year Survival in Carcinoma of the Rectum and Rectosigmoid. C. W. Mayo and O. A. Fly. Surg. Gynec. & Obst. 103:94-100 (July) 1956 [Chicago].

A comparison of the survival rates of 1,146 patients with carcinoma of the rectum and rectosigmoid is presented, with emphasis on the three operative procedures (anterior resection, one-stage combined abdominoperineal resection, and posterior resection) with which they were treated at the Mayo Clinic. The results of these survival studies in the controversial groups, that is, patients whose lesions are located between 6 and 15 cm. from the dentate margin, indicate that a sphincter-preserving procedure, such as anterior resection, is as curative as is one-stage combined abdominoperineal resection or two-stage posterior resection. No criticism can be made of the selection of a sphincter-sacrificing technique for lesions in the region of the anus and in the distal 5 cm. of the rectum. The grade of malignancy of the lesion was not a significant factor in this analysis, as the distribution was essentially the same in each group studied. There was no significant variation in the number of patients with or without nodal metastasis in the various segments of the rectum and sigmoid studied. The level of the lesion in relation to the peritoneal reflection has little influence on the survival rates.

Congenital Arteriovenous Fistulas in the Extremities: An Analysis of Sixty-Nine Cases. G. Coursley, J. C. Ivins and N. W. Barker. Angiology 7:201-217 (June) 1956 [Baltimore].

The authors define an arteriovenous fistula as "a vascular abnormality in which there are one or more direct or indirect communications between an artery and a vein without any intervening capillary bed." Such fistulas may be classified as either "acquired" (traumatic) or "congenital" in origin. Congenital arteriovenous fistulas may be located in almost any part of the body, but they are found most commonly in the extremities. The present paper is concerned only with congenital arteriovenous fistulas of the extremities, the treatment of which is known to be difficult and generally unsatisfactory. The clinical, laboratory, and therapeutic aspects of congenital arteriovenous fistulas seen at the Mayo Clinic in 69 patients during a 19-year period were evaluated. The arteriovenous shunts, invariably multiple, may be localized or, more commonly, diffuse. Excision of localized fistulas often produces good results, whereas it is very difficult or even impossible to eradicate diffuse fistulas and still preserve the limb. Associated involvement of bone results in recurrences of the fistulas after surgical treatment and frequently necessitates a major amputation of the affected limb. Partial surgical excision may alter the local hemodynamics so that actual or potential arteriovenous shunts open up at a more proximal level, giving rise to a recurrence, which necessitates further surgical treatment and very frequently leads to loss of the limb because of inability to preserve function in the limb.

Results of Surgical Treatment of Peptic Ulcer in Municipal Hospital of San Juan. R. Arredondo. Bol. Asoc. méd. Puerto Rico 48:162-168 (April) 1956 (In Spanish) [San Juan, P. R.].

Two hundred fifty-one patients with peptic ulcer were observed in the Municipal Hospital of San Juan from 1946 to 1955. In 63 patients an exploratory laparotomy was performed within the first five hours after the perforation of a gastric ulcer. The operation consisted of gastrorrhaphy or duodenorrhaphy in 55 patients and of subtotal gastrectomy in 5. Antibiotics and intravenous fluid were administered. A recurrence took place in four patients during the first six months. The patients had either a gastrectomy or a gastrorrhaphy. Fatal complications occurred in one. Follow-up observations were made on 43 patients, of whom 24 had no symptoms and 19 required a more definitive operation after failure of the treatment. Gastrectomy was performed on 188 patients of an average age of 48 years. Roentgen examination and an exploratory laparotomy revealed a duodenal ulcer in 146 patients, pyloric ulcer in 17, and gastric ulcer in 25. Subtotal gastrectomy was performed in 174 patients, total gastrectomy in 10, tubular gastrectomy in one, and gastroenterostomy with vagotomy in 3. Blood transfusion, intravenous fluid, and antibiotics were given these patients. Immediate complications were leakage from the duodenal stump in two patients, postoperative hemorrhage in seven, subphrenic abscess in one, phlebitis in four, hypostatic pneumonia in nine, and obstruction of anastomosis in three. There were no deaths. Late complications were marginal ulcer in three patients and late obstruction in nine. There were no late deaths. A follow-up study was made in 136 cases. The results of the operation were satisfactory. The following complications were observed: dizziness, perspiration, and general debility, which were transient; hypochromic anemia, which appeared in 9 patients and was controlled by drugs; and urgent defecation within 30 minutes after ingestion of food, which appeared in 17 patients and spontaneously disappeared within four or six months without any treatment. The patients gained weight (between 2 and 7 kg. [4.5 and 15.5 lb.]) after the operation.

Thromboangiitis Obliterans in Women: Gangrene; Blood Vessel Graft. T. Hiertonn, F. Lund and J. Philipson. Angiology 7:233-242 (June) 1956 [Baltimore].

Thromboangiitis obliterans is very rare in women. While the literature contains reports on thousands of men with this disease, only about 60 women with this disease have been reported. This paper presents observations on a 43-year-old woman with symptoms considered typical of thromboangiitis obliterans. She had severe peripheral arterial insufficiency and necrosis of the toes of the right foot. Amputation above or possibly below the knee joint was considered. Arteriography revealed a 10-cm. arterial obstruction in the femoral popliteal artery. Local resection and reconstruction of the arterial pathway with a venous graft led to rapid regression of the severe signs of ischemia and healing of the ulcers. The formerly incapacitated woman was in very good condition three and one-half years after the operation. In order not to overlook the possibility of this type of surgical therapy, it is important that a careful analysis of the arterial network be made in cases of peripheral arterial insufficiency. The result in this case demonstrates the importance of reconstruction of the main artery even in the presence of areas of occlusion in medium-sized and small distal arteries.

Treatment of Low-Back and Sciatic Pain by the Injection of Hydrocortisone into Degenerated Intervertebral Discs. H. L. Feffer. J. Bone & Joint Surg. 38A:585-592 (June) 1956 [Boston].

The local anti-inflammatory action of hydrocortisone and its value in reversing or blocking the inflammatory process in degenerative joint disease, tendinitis, tenosynovitis, and related conditions having been verified, it was deduced that hydrocortisone should have a like beneficial effect when injected into the acutely swollen intervertebral disk, if the process had not become irreversible; that is, if complete rupture had not occurred. Only one injection was made. The hydrocortisone solution and an iodopyracet solution were combined so that a nucleogram could be made at the same time the therapeutic solution was injected. The nucleogram served a dual purpose; the immediate condition of the disk was determined and the nature of the ensuing clinical response to the hydrocortisone could be evaluated and related to the state of degeneration of the disk. The patient lies in the flexed position on his side on the x-ray table, and the disk under investigation is centered for a lateral roentgenogram. The disk is punctured by inserting a 4-in., 22-gauge regional block needle through an anesthetized area 1.5 cm. lateral to the upper margin of the spinous process of the subjacent vertebra. Entrance into the annulus fibrosus is accompanied by a sensation of rubbery resistance; after piercing the annulus, the needle is inserted about one more centimeter. The two lower lumbar disks are punctured routinely unless there is a definite reason for not puncturing one in particular and unless there is a reason for puncturing one at a higher level. With the needles in place, a lateral roentgenogram is made and the accuracy of the position of the needles for injection is verified. The material to be injected is made up in a syringe by mixing 3 cc. of a 35% solution of iodopyracet with 1 cc. of a solution containing 50 mg. of hydrocortisone. Each interspace is injected under moderate pressure, and the needles are withdrawn. Trunk movements are made to help diffusion of the solution.

The author presents the results obtained in the first 60 patients. The maximum follow-up period was eight months. Nucleograms of 55 patients demonstrated pathological lesions of the intervertebral disks. Thirty-seven patients experienced rapid remission of symptoms after injection of hydrocortisone; 18 failed to respond. Surgical exploration of the involved disks in 16 of the 18 failures demonstrated irreversible changes. These results suggest that the method not only permits rapid arrest of an acute intervertebral disk herniation but also demonstrates early which disks will require surgical intervention. This would prevent morbidity and economic loss.

The Osteogenetic Phases of Regeneration of Bone: A Historical and Experimental Study. W. Axhausen. J. Bone & Joint Surg. 38A:593-600 (June) 1956 [Boston].

During the early investigations of the regeneration of bone, there was a conflict between the osteoblastic theory and the induction theory. The work of Orell and Levander contributed evidence to both theories. In the experiments described in this paper, the osteogenetic significance of the soft-tissue components of bone—periosteum, marrow, and living cells of the bone canals—was established anew. Even in adults, the latent osteogenetic cells were brought to proliferation and function within several days by the activating influence of bone necrosis. In order to clarify the effect of the nonspecific connective tissue of bone substance, autogenous frozen-bone grafts covered with periosteum were transplanted into dogs. Up to the 14th day no evidence of bone formation could be found on histological examination. Histological evidence of necrosis of the periosteum is proof of the fact that the osteogenetic tissue was completely killed by freezing. Since new bone formation and delayed bone regeneration of the graft took place after some time (even up to 53 days), a transformation of the nonspecific connective tissue of the host into osteogenetic tissue must have taken place. Consequently, the osteoblastic and induction theories are combined into a unified concept. Bone regeneration occurs in two osteogenetic phases. The first and, physiologically, most important phase originates in the preexisting specific cells and begins after several days. The inception of the second phase, however, originating in the nonspecific connective tissue, requires several weeks. Both phases are stimulated by the activating influence of the bone necrosis.

Skeletal Cryptococcosis (Torulosis): Report of a Case and Review of the Literature. H. R. Gosling and W. S. Gilmer, Jr. J. Bone & Joint Surg. 38A:660-668 (June) 1956 [Boston].

The most common form of torulosis (cryptococcosis) in human beings is chronic meningoencephalitis with fatal termination. Infection of the skeletal system by this fungus is rare. The authors found records of 24 patients with the skeletal form of torulosis, but in 4 of these patients only the skull was infected and in 3 of these the involvement was secondary to the primary disease of the brain and meninges. Primary skeletal torulosis was confirmed in 18 patients. The authors report a new case of torulosis in a 10-year-old Negro boy who had injured his left knee in a fall from a bicycle two weeks before he was hospitalized. Greenish-yellow purulent material was repeatedly aspirated from the knee-joint. Penicillin, streptomycin, and hyaluronidase were injected locally. Several weeks later the patient began to complain of pain in the right elbow, and a swelling of the right sternoclavicular joint was noted. Roentgenographic examination revealed bone destruction in the medial end of the clavicle and an osteolytic lesion in the neck of the right radius. The diagnosis based on the pathological findings was chronic granulomatous osteomyelitis, probably torulosis (cryptococcosis). Cultures and animal inoculations corroborated this diagnosis. The boy recovered after surgical and antibiotic treatment of the bone lesions.

The authors gained the impression that the prognosis for patients in whom skeletal torulosis (cryptococcosis) is associated with "generalized" or meningeal involvement is poor. There have been no recorded survivals of such patients in spite of therapy. The prognosis for patients with localized bone lesions is good regardless of the therapy employed; however, surgical removal of the diseased bone will enhance healing and will lessen the possibility of dissemination of the disease.

Hypertension After Nephrectomy and After Intervention on the Extrarenal Urinary Region. G. Rallo. Clinica 16:165-175 (No 3) 1956 (In Italian) [Bologna, Italy].

The author believes that surgical intervention is indicated in hypertensive patients with kidney affections. The operation should be performed as soon as possible in order to avoid irreversible kidney lesions. Nephrectomy was performed in 50 patients with hypertension and kidney lesions. Fifteen had tuberculosis, 12 hydronephrosis, 12 neoplasia, and 11 kidney calculosis. Results were good in 16 patients, or 32%, fair in 6, or 12%; and negative in 28, or 56%. The age and sex of the patient have no effect on the hypotensive results of nephrectomy. A drop in pressure, unless dependent on other causes, occurs only in those patients whose remaining kidney is free of lesions. Fifty hypertensive patients with extrarenal disease were also studied. Twenty had a prostatic tumor, 15 had calculosis of the urinary bladder, and 20 had pyeloureteral calculosis. Results were good in 63.6% of the patients, fair in 9.06%, and negative in 27%. Results were best when the damage to the kidney was in its acute stage. Obstruction that has existed for a long time creates an irreversible lesion in the adrenal parenchyma, and the arterial pressure does not drop even after the removal of the obstruction. In such cases and in cases of unilateral lesion, hypotension can be obtained by a nephrectomy.

Solitary Eosinophilic Granuloma of Bone. T. Hunter. J. Bone & Joint Surg. 38B:545-557 (May) 1956 [London, England].

Hunter reports on eight patients with solitary eosinophilic granuloma of bone. The fact that three were observed in one hospital during the past year indicates that the lesion is not extremely rare. Although the condition was established as a pathological and clinical entity in 1940, its etiology has not been clarified. It occurs chiefly in children and young adults, and, although the sex incidence in this small series of cases was equal, as a rule it occurs more often in males. The skull, ribs, femur, vertebrae, pelvis, mandible, humerus, and clavicle are most commonly involved. The main histological characteristics—sheet-like formation of histiocytes ("the basic component"); more or less conspicuous numbers of eosinophilic cells, especially of eosinophilic leukocytes; and actively phagocytic multinuclear giant cells—were observed in seven of the eight patients. In the remaining patient, eosinophilic cells were a less conspicuous feature, but their presence in focal collections against a background of fibroblasts and pale-staining cells with abundant vacuolated cytoplasm was sufficiently diagnostic of the eosinophilic granuloma group.

Clinically, eosinophilic granuloma may be a completely silent lesion. In three of the eight patients, symptoms were first noticed after an injury. None showed any significant systemic disturbance. Local pain is usually the presenting symptom, and swelling may occur if the lesion is in the long bones. Laboratory studies are of slight importance for the diagnosis, except that leukocytosis is occasionally detected; the erythrocyte-sedimentation rate may be raised, and eosinophilia has been recorded as an occasional finding but was not found in the present cases. Radiographically, the lesion presents as an area of endosteal destruction, irregular in outline, or with a smooth contour producing a "punched out" effect. As it enlarges, it eventually erodes the cortex, a section of which may disappear completely or partly. Subperiosteal new bone formation is regarded by most authors as unusual. When it occurs, it is said to be associated with perforation of the cortex. Four of the present patients showed subperiosteal new bone formation. The radiographs in one patient in particular showed well defined "onion-skin" layers resembling the classic description of

Ewing's tumor. Cortical perforation into the overlying soft tissues was observed at operation in only one of these patients, but all four showed radiographic evidence of complete destruction of parts of the original cortex.

As regards complications, the author says that the fracture occurring in one patient does not entirely merit such a description, since it occurred soon after a biopsy operation during which part of the femoral cortex had been removed. The radiographs of a second patient showed a crack fracture through the site of a clavicular lesion. The involvement of the nerve roots in a patient with profound motor weakness is of interest chiefly because of the rapidity of the disappearance of the paralysis. The prognosis of eosinophilic granuloma is favorable in that complete and spontaneous recovery of a lesion has been observed in patients with multiple foci. In view of the lack of specific diagnostic criteria short of biopsy, however, it follows that solitary eosinophilic granulomas of bone, once demonstrated radiographically, are likely to be explored. To curettage is then attributed the subsequent healing of the lesion. Diagnostic considerations and healing apart, curettage appears to fulfil an additional function in rapidly relieving the pain, probably by decompression of the lesion. Since resolution may occur either spontaneously or after curettage, the place of radiotherapy in the treatment of eosinophilic granuloma is difficult to assess. It was employed originally as an empirical measure, and, although most writers agree that it is successful in relieving pain, there is some doubt as to its actual effect on the pathological process.

NEUROLOGY & PSYCHIATRY

Cystic Astrocytoma of the Cerebellum, an Anatomoclinical Study of Forty-Four Cases with Operative Results. P. Wertheimer and M. Corradi. Semaine hôp. Paris 32:2179-2188 (June 22) 1956 (In French) [Paris, France].

The authors studied 44 cases of cystic astrocytoma of the cerebellum. The radiological, ventriculographic, and electroencephalographic characteristics of these tumors allow the diagnosis to be made before the occurrence of complications due to intracranial hypertension. Eighteen astrocytomas occupied the left lobe, 14 occupied the right lobe, 5 were in the vermis, 5 occupied both the vermis and a hemisphere, and 2 were limited to the fourth ventricle. The average duration of preoperative development was eight or nine months. Signs of intracranial hypertension are early symptoms. Signs of irritation of the centers of the floor of the fourth ventricle are less frequent. Headache, vomiting, vertigo, and disturbance of balance are frequently but not necessarily present. In 38% of these patients headache alone, almost always of an intermittent and paroxysmal nature, appeared in the beginning. Several of the patients were symtom-free for from three to four weeks up to several months.

At the height of the disease, headache, vomiting, and vertigo are paroxysmal but on a continuous basis. At this stage, when vomiting is present in 90% of the cases, signs of intracranial hypertension are confirmed by neurological examination and standard radiographs. Confusion is not an indispensable corollary of intracranial hypertension; only 3 of the 44 patients were confused. In 55% of the cases there were clinical signs of obstruction to the cerebrospinal fluid flow, notably collateral venous circulation in the forehead and upper eyelids. Hypotonia, a major sign (found in 18% of the patients), is almost always homolateral in relation to the lesion and is frequently localized in only one member. Signs of cerebral incoordination are always homolateral in relation to the lesion and occur most frequently in the lower members. Bilateral papillary edema was present in 27 patients. Stasis was almost always accompanied by a diminution of visual acuity, generally between ⅔ and ⅓. This examination is very important, but the absence of papillary edema does not eliminate possibility of a neoformation of the cerebellum. Labyrinthine symptomatology is especially evident in anterolateral cerebellar lesions compressing the nuclei or the vestibular roots. These signs, although disharmonious, must frequently be credited to a syndrome of intracranial hypertension. They rarely clarify the nature or extent of the causal lesion. The slow development of cystic astrocytomas and the frequency with which they appear in young subjects usually lead to changes in the cranium that make it possible to detect intracranial hypertension on radiological examination. The younger the patient and the slower the development, the clearer will be the signs of hypertension.

An electroencephalographic examination was made of 16 patients. Three kinds of signs were distinguished: false, suggestive in view of the clinical picture, and characteristic. The last-named type (25% of the cases) includes slow occipital unilateral waves not always on the side of the tumor and sometimes associated with slow bifrontal waves provoked by hyperpnea. Ventriculography permits confirmation of the clinical diagnosis of tumor of the posterior cerebral cavity. It frequently indicates exactly the hemispheric or vermian seat of the lesion and improves diagnosis by giving information concerning the general state of the ventricular system. Clinical forms of astrocytoma may be subdivided into those of the child and the adolescent as opposed to those of the adult. The child or the adolescent is in good condition. If obnubilation exists, it is light. There are episodes of vomiting and headache. The cranium is slightly enlarged in volume, the posterior cavity may rise a little, the nape is stiff, and moving the head is painful and produces vertigo; pains, especially in the nape, radiate dorsally. Neurological examination shows a disharmonious cerebellar vestibular syndrome with cerebellar incoordination, often unilateral, accompanied by a paralysis of certain cranial nerves, especially of the sixth and seventh pair, and signs of moderate compression of the motor pathways with beginning papillary stasis.

Of the 44 patients operated upon at Lyon from 1932 to 1955, 7 died in the first days after the intervention. In two of these the tumor had invaded the cerebral trunk. In the following three months, nine died, five in a state of profound cachexia and four from respiratory disturbances. Fifty-six per cent of the patients operated on during the 12 years from 1932 to 1943 died, whereas, during the 12 years from 1944 to 1955, only 14% died. This illustrates the improvement of surgical technique and enrichment of experience. Neurological examination in 20 of the surviving patients is at present completely negative. Six recurrences at intervals of from 1 to 11 years after the first excision were reported.

Acute Hemorrhagic Encephalitis. K. Kristiansen, W. Harkmark and M. M. Cohen. Neurology 6:503-509 (July) 1956 [Minneapolis].

Kristiansen and associates discuss observations on five patients with acute hemorrhagic encephalitis who were observed in the seven-month period ending June, 1954, at a hospital in Oslo, Norway. The series included three men and two women ranging in age from 31 to 51 years. Headache or elevation of temperature preceded the neurological symptoms in most of these patients; in two a productive cough indicated a preceding upper respiratory infection. Symptoms of nervous system involvement then appeared and were often localizing. Hemiparesis and stupor were most common; hemihypesthesia, quadriplegia, central facial palsy, papilledema, nuchal rigidity, confusion, disorientation, hallucinations, diplopia, and dysphasia were less frequently observed. The results of laboratory tests were rather inconstant. The angiographic findings generally suggested a space-occupying lesion. The focal cerebral symptoms together with evidence of increased intracranial pressure and angiographic abnormalities led to surgical procedures in all five cases. Craniotomy and cerebral biopsy were performed in four patients in whom angiography exhibited displaced vessels. Three patients died during the acute disease and two survived. One surviving patient now presents only an incomplete left-sided hemianopsia despite his early hemiparesis, diplopia, disorientation, and stupor. The second survivor exhibited little improvement after the acute stage of illness. Progressive mental deterioration, disorientation, and confusion necessitate institutionalization.

The term acute hemorrhagic encephalitis was suggested by Strumpell in 1891 to describe a condition characterized pathologically by necrosis, hemorrhage, and demyelination in the cerebral white matter. In subsequent reports elaborating the pathological features of this disorder, the lesions were often noted to be asymmetric, with one hemisphere exhibiting more severe damage than the other. Although the pathological changes have been adequately described in fatal cases, the pathogenesis and the etiological agent remain unknown. This hemorrhagic encephalitis has been known to occur in conjunction with viral infection, allergic reaction, and intoxication. The fact that the five cases presented in this paper occurred within a brief period of seven months suggests the possibility of toxic or infectious causation.

Current Status of Chlorpromazine and Reserpine in Psychiatric Practice. B. C. Schiele, R. W. Anderson and W. Simon. Journal-Lancet 76:179-185 (July) 1956 [Minneapolis].

Reserpine and chlorpromazine are the most widely used of the so-called "tranquilizers." These drugs induce a state of quietude with little or no clouding of consciousness, an effect that makes them the most useful preparations available for the management of acute states of excitement. Their use has resulted in a reduction of electroshock and insulin shock treatments and of lobotomy. These tranquilizers are less effective in the treatment of office than of hospitalized psychiatric patients. They facilitate psychotherapy, but they are not a substitute for it. Some patients do not obtain beneficial effects even when the drugs are given in large doses. While most patients tolerate either or both without difficulty, annoying side-reactions may occur, particularly with chlorpromazine. The action of reserpine appears to be slower, less potent, and less toxic. Chlorpromazine is preferred in the treatment of excited patients when rapid action is required. Neither drug seems to ameliorate states of depression. While many psychiatric patients have improved and some have been discharged, a large-scale emptying of state hospitals has not occurred. The drugs are more effective in acute than in chronic disorders. Although the fact that pharmacological agents are now available that relieve distressing symptoms for so many patients is very encouraging, the authors cannot conceive of any drug that will alter basic personality structure.

Diagnostic Suitability and Limits of Complement-Fixation Reaction in Patients with Poliomyelitis. E. Berger and M. Vest. Schweiz. med. Wchnschr. 86:776-778 (July 7) 1956 (In German) [Basel, Switzerland].

Complement-fixation tests according to Fulton and Dumbell's technique were performed on blood samples obtained from 98 patients with poliomyelitis associated with paresis, 103 patients with serous meningitis who were suspected of having poliomyelitis, 45 patients with various febrile infections not caused by the poliomyelitis virus, and 27 patients with afebrile diseases. A positive reaction of the blood to the test was obtained in 85 (86.7%) of the 98 patients with poliomyelitis associated with paresis. These results corresponded with those obtained by many other workers, although they may have used other techniques for the complement-fixation test. A positive reaction of the blood to the complement-fixation test was obtained in 47 (45.6%) of the 103 patients with serous meningitis of doubtful origin. The total number of positive reactions was obtained by testing a second blood sample with regard to the presence of complement-fixing antibodies from 7 to 12 days after a negative reaction of the first blood sample had been obtained at the end of the first week of the patient's disease. The number of positive results obtained under these conditions corresponded to those obtained by other workers who used the method of direct demonstration of virus by growth of the pathogenic agent in tissue culture.

The complement-fixation reaction is an aid in confirming the clinical diagnosis of poliomyelitis. The complement-fixation reaction is of particular value for the diagnosis of nonparalytic forms of poliomyelitis the cause of which is not clear. The diagnostic value of the complement-fixation reaction, however, has its limits, primarily because of the observation of negative reactions to the test in patients with a definite clinical aspect of poliomyelitis. A positive reaction to the complement-fixation test in the absence of clinical criteria for poliomyelitis was observed in 8 (11%) of the 72 patients with infections which were not caused by the poliomyelitis virus. Although inapparent infections with poliomyelitis virus may produce complement-fixing antibodies, it cannot be definitely stated that causative agents other than poliomyelitis viruses may not be responsible for a positive complement reaction. The complement-fixation reaction does not seem to be an appropriate means of establishing the type of the causative virus in patients with poliomyelitis.

GYNECOLOGY & OBSTETRICS

Non-Suppurative Osteitis Pubis in the Female. L. L. Wiltse and C. H. Frantz. J. Bone & Joint Surg. 38A:500-516 (June) 1956 [Boston].

The authors report the occurrence in 13 women of a disease that they believe is a definite clinical entity related to, but not identical with, osteitis pubis in men. The disease was nonsuppurative and noninflammatory and developed in the anterior portion of the pelvic girdle. In five of the women, the symptoms were first noted during pregnancy; in five others, the symptoms appeared within two months after delivery; in one, they appeared after extensive pelvic surgery; and in two they developed after an injury. Four illustrative case histories are presented, one from each of these four groups.

The typical patient with this disease (usually a young woman) begins to experience pain about the symphysis within a few months after the occurrence of some event capable of producing trauma in the adjacent structures. A physical examination reveals tenderness directly over the symphysis, although no swelling or fluctuation is seen. Blood, urine, and temperature are generally normal, but the symphysis frequently shows instability. The pain often becomes so severe that the woman is completely bedridden and can neither sit nor stand. As the disease progresses, the roentgenograms may show spotty demineralization of the bone adjacent to the symphysis, widening of the symphysial gap, and gradual development of sclerosis and narrowing. The disease is self-limited, but it may persist for weeks or years. Treatment was symptomatic in all of the 13 patients presented. It consisted of bed rest. warm packs, and analgesics. One of the patients who had been attended by a number of doctors received a variety of treatments, including x-ray therapy, corticotropin, cortisone, and phenylbutazone. The authors comment on osteitis pubis in male patients and present their own concept of the etiology, which admittedly leaves some factors unexplained. They believe that the condition referred to as osteitis pubis is a localized reflex neurovascular dystrophy brought about by a combination of trauma and predisposing changes at the symphysis. The changes at the symphysis are due to the influence of certain hormones and are of the nature of, but more pronounced than, those that normally occur during pregnancy.

Recent Research in Physiology of Breast Applied to Mammary Cancer. G. Hadfield. Brit. M. J. 1:1507-1511 (June 30) 1956 [London, England].

According to Hadfield, about 50% of human breast cancers are hormone-dependent and do not have the gloomy and mysterious attribute of "autonomy" so often regarded as the essential biological characteristic of all malignant tumors. A breast cancer is said to be hormone-dependent if progressive proliferation of its infiltrating and metastasizing cells is conditioned by an adequate supply of the specific mammotropic hormones responsible for physiological mammogenesis. The author reviews experimental studies on the hormonal control of the breast and discusses the presence of mammotropic hormones in the urine. Normal breast growth is controlled by the synergistic action of the pituitary hormone prolactin acting at a relatively high concentration, with ovarian estrogen acting at a relatively low one. Combined oophorectomy and adrenalectomy deprive the breast cancer of estrogenic steroids, and growth regression follows if the tumor is hormone-dependent. This effect seems to be almost always temporary; estrogen production is slowly reestablished, and progressive growth of the tumor recurs, probably when estrogen production from an unknown site reaches the low level required for normal mammogenesis. Total hypophysectomy in all probability completely deprives the tumor of estrogen and prolactin. This operation can have no effect on the growth of a hormone-independent tumor. The urine of all premenopausal women and of approximately 50% of postmenopausal women contains one or more mammotropic hormones. It seems probable that it contains prolactin. If the urine of a breast-cancer patient has no mammotropic activity, it seems very probable that her cancer would not be hormone-dependent and that hypophysectomy would have no effect on its progressive growth.

Further Experience with Apresoline in Toxemia and Hypertension of Pregnancy. H. L. Riva, W. L. Pickhardt, R. H. Holzworth and R. L. Sherman. Am. J. Obst. & Gynec. 72:48-55 (July) 1956 [St. Louis].

Results of 1-hydrazinophthalazine (Apresoline) therapy in 67 pregnant toxemic and hypertensive patients are presented. The patients were divided into the following groups: preeclampsia, hypertension of labor, hypertensive vascular disease, hypertension with superimposed toxemia, eclampsia, and preeclampsia with chronic glomerulonephritis. The mean vasodepressor response was significant in all six groups; it was less marked in the patients with a previous history of hypertension. The average tachycardia after administration of Apresoline was noted within 30 minutes and amounted to an increase of about 20 to 30 mm. Hg. The infant mortality, amounting to about 7%, was not attributed to the use of Apresoline. Oral or subcutaneous administration may have a place in a few selected nonacute cases. The intravenous drip method of administering Apresoline was found to be the most efficacious in maintaining a desired lowering of blood pressure and so avoiding a precipitous drop in blood pressure. Apresoline is highly recommended for the control of the hypertensive aspects of preeclampsia and hypertension in pregnancy.

Comments on the Richardson Pregnancy Test and the Rapp-Richardson Saliva Prenatal Sex Determination Test. W. G. Dobson and A. G. Gornal. Am. J. Obst. & Gynec. 72:70-74 (July) 1956 [St. Louis].

The Richardson pregnancy test is questioned both as to its reliability and the theoretical basis on which it was proposed. The authors obtained an accuracy of about 75% in pregnant patients and 47% in nonpregnant women. Evidence is presented that the method of extraction does not effect any separation or purification of an estrone fraction and that, even if it did, the amount of free estrone in the urine of pregnant women is much too small to be detected with 2, 4-dinitrophenylhydrazine. The Rapp-Richardson saliva prenatal sex-determination test is subject to similar criticism and had an accuracy that indicated that the result was in no way determined by the sex of the fetus.

Fertility After Tubal Pregnancy. S. Bender. J. Obst. & Gynaec. Brit. Emp. 63:400-403 (June) 1956 [London, England].

Two hundred sixty-four of 305 women who had been operated on for tubal pregnancy between 1946 and 1952 were followed up. One or more pregnancies occurred after this operation in 116, or 44%, of these 264 women. On the basis of this follow-up, it appears that, of each 100 women who have had tubal gestations, 56 do not conceive again and 44 do. Of the 56 who remain sterile, 7 have had a sterilizing operation. In another six, the remaining tube has been shown by salpingography to be blocked. There must be others in whom the remaining tube is blocked, but the fact has not been proved. In addition, at least 3 of the 56 do not become pregnant because they consistently practise contraception purely for fear of another ectopic pregnancy. Doubtless there are others who practise contraception for other reasons. In 44 of 100 conception does occur again; but this is a minimum figure because of the limited time of follow-up, at the most seven years. If all of these women were followed to the menopause, the conception rate would probably approach 50%. Of the 44 who do conceive, 32 produce live babies. This means that only one in three women who have had a tubal pregnancy will thereafter have a live child.

The conception rate was notably higher in the 130 women under the age of 30 at the time of operation (54%) than in the 134 older patients (34%). The conception rate was the same in the previously parous and the previously nulliparous. Of particular interest is the relationship between the type of operation performed and the subsequent conception rate. Nothing was done at laparotomy in four women, because tubal abortion was seen to be complete; all four became pregnant again. This is a reminder that probably most cases of tubal pregnancy are never diagnosed. Probably the commonest fate of the fertilized egg that implants in the tube is that it dies and is absorbed. Of four women on whom salpingotomy was performed, three became pregnant again. In the majority of cases (187) salpingectomy was carried out, and 80 of these women became pregnant again, a conception rate of 42.7%. In 51 women, salpingo-oophorectomy was performed, and 29 of these became pregnant again, a conception rate of 56.8%. Statistically, the difference between these rates is barely significant, but the author cites evidence indicating that pregnancy is more likely to occur again when tubal pregnancy is treated by the removal of both tube and ovary rather than the tube alone. Inspection of the nonpregnant tube for patency, salpingotomy instead of salpingectomy when feasible, but salpingo-oophorectomy when salpingotomy is not possible, are cited as the chief measures to be taken in women who wish to become pregnant again after a tubal pregnancy.

Tuberculosis and Pregnancy. S. Jacobs. Dis. Chest 30:43-49 (July) 1956 [Chicago].

The author studied a series of 64 tuberculous women who received obstetric care at the Charity Hospital of Louisiana. Most of them were young Negro women receiving antibiotic therapy. It was found that pregnancy does impose an additional stress on tuberculous women, but quantitative evaluation of this stress is almost impossible. Most women, particularly those who are anxious to have children, can tolerate this stress when treated with the antibiotics currently available. To reduce this stress to the minimum, tuberculous women should be advised to defer pregnancy until the disease has been inactive at least two years if minimal, three years if moderately advanced, and five years if far advanced. Experience with a relatively small group suggests that, if this precaution is observed, even multiple pregnancies are tolerated without reactivation of the tuberculosis. To detect tuberculosis, each obstetric patient should have a chest x-ray film examination as soon as pregnancy has been discovered. When tuberculosis is found in a pregnant woman, treatment with antibiotics and rest should be started at once precisely as during the nongravid state. Other methods of therapy should be added as needed. The patient may be assured that, with adequate therapy, she will continue to improve despite the pregnancy, may be delivered of a normal child, and will be noninfectious by the time of confinement.

PEDIATRICS

Prevention of Extension of Tuberculosis in Early Childhood. P. Zoelch. Deutsche med. Wchnschr. 81:1082-1084 (July 6) 1956 (In German) [Stuttgart, Germany].

To ascertain the value of isoniazid in preventing the dissemination or generalization of tuberculosis, the author sent questionnaires to 15 children's clinics and to 5 sanatoriums for tuberculous children. The question whether isoniazid prevents generalization of tuberculosis was generally answered in the affirmative. Particularly impressive was the fact that isoniazid given by mouth prevented threatening meningitis in young children with miliary tuberculosis. Only two children were mentioned in whom meningitis resulted from miliary tuberculosis, whereas before the introduction of isoniazid tuberculous meningitis developed in about 50% of the children with miliary tuberculosis of the lungs. The author also learned of five children in whom tuberculous meningitis developed after other forms of tuberculosis, while they were being treated with isoniazid. In his own sanitarium the author observed a young child with tuberculous pneumonitis and caseous degeneration in whom fatal tuberculous meningitis developed after three months of combined administration of isoniazid and streptomycin. In two other patients with tuberculous lung infiltrations, meningeal symptoms developed temporarily during isoniazid therapy. The author believes that in these two patients tuberculous meningitis would doubtless have developed in the absence of the administration of isoniazid. Miliary tuberculosis rarely developed during isoniazid therapy.

The question of the occurrence of hematogenous dissemination of other forms during isoniazid therapy was answered variously. Skeletal, pleural, renal, and lymph-node involvements were occasionally observed, but there was always the possibility that these disseminations existed before the isoniazid therapy was begun. The toxic effects of isoniazid were mostly minor and easily reversible. To determine whether invasion and breakdown of the bronchial lymph nodes occurs more frequently with than without isoniazid therapy, the incidence of recurrent pulmonary exacerbations, which, like aspiration infiltration, atelectasis, and mixed forms, are often caused by perforation of lymph nodes, was investigated. The incidence of these complications with and without isoniazid therapy differed in various institutions, but the author believes that differences in case material existed and that pulmonary recurrences were not essentially greater with than without tuberculostatic therapy. As regards the age of the patients who should receive isoniazid therapy to prevent dissemination of tuberculosis, it is advisable in children under 2 years of age but not in those over this age. The beginning dose is 5 mg. per kilogram of body weight, and this is later increased to 10 mg. per kilogram. Periods of treatment lasting one month are followed by a treatment-free interval of equal length, and in this way isoniazid therapy may be continued for one year.

Myeloid Leukemia in Children. P. Giraud, R. Bernard, T. Mangipan and F. Challiol. Semaine hôp. Paris 32:2444-2451 (July 10-14) 1956 (In French) [Paris, France].

The authors observed myeloid leukemia in three boys aged 11, 5, and 13. They cite some manifestations of the disease, rare in children, that are more frequent in the child than in the adult: (1) ocular involvement, found in two of the cases, in the form of classic retinitis with papillary edema, small punctate and juxtapapillary hemorrhages, large venous bilateral congestion, and white perivascular infiltrates; (2) moderate renal attack manifesting itself by a simple and relatively frequent albuminuria; (3) cutaneous lesions the size of a pea to that of a nut, violet-colored and histologically characteristic; and (4) generalized or localized adenopathy, sometimes microulcerated. Apart from these relatively rare manifestations, the clinical aspect of myeloid leukemia in children does not differ notably from that found in adults with this disease. In infants the disease may be mistaken for the Von Jacksch-Suzet syndrome. The basic clinical feature is splenomegaly, and the blood picture commonly shows the presence of anemia and platelet deficiency. The total course of the disease toward a fatal end rarely seems to exceed three years. The terminal complication usually consists of hemorrhages with leukoblastic transformation. Death was due to cerebral thrombosis in one of the three reported cases. Although no newer form of chemical therapy has as yet been tested in the child, such therapy might possibly afford a longer survival time in this fatal affection.

The Immunization of Allergic Children: Part I. Special Reference to Eczema Vaccinatum. B. A. Johnson and S. C. Dees. North Carolina M. J. 17:304-309 (July) 1956 [Winston-Salem, N. C.].

Eczema vaccinatum is a preventable disease. Eight cases occurred in 415 cases of atopic eczema, representing about 2 cases of eczema vaccinatum among each 100 cases of eczema. All the patients were 5½ years of age or younger, and death occurred in the case of a 6-month-old infant. The vaccinated 5-year-old and 6-year-old preschool and school-aged sibling constitutes the greatest single menace as a contact with the eczematous child. A vaccinated person should be considered a danger to the eczematous child until the scab from the vaccination site has fallen. The history of contact with a vaccinated person is the most valuable aid to the physician in the diagnosis of eczema vaccinatum. The authors urge adherence to the contraindications of smallpox vaccination. Persons who have a skin disease or who are intimate contacts of a person with a skin disease should never be vaccinated.

Pheochromocytoma in a Thirteen-Year-Old Child. P. Giraud, M. Salmon, R. Bernard and others. Semaine hôp. Paris 32:2435-2440 (July 10-14) 1956 (In French) [Paris, France].

The authors report the case of a 13-year-old child who showed permanent arterial hypertension. Diagnosis of the presence of a pheochromocytoma was confirmed by the Regitine test. The tumor was removed and the child recovered. The authors analyze a number of reports in the literature of pheochromocytoma in children. Hypertensive paroxysmal crises are rare because this tumor usually produces permanent hypertension in children. Retropneumoperitoneum is very helpful in the diagnosis of pheochromocytoma, but its interpretation may be difficult. Pharmacodynamic tests are simple and more reliable. When they are positive the presence of an adrenalin-secreting tumor is confirmed. Of these tests, the one with Regitine is particularly recommendable, as it is reliable and innocuous. The only treatment for such tumors is surgical removal, which carries a high death rate as a result of operative accidents, paroxysmal hypertension, or postoperative collapse. Complete and definitive recovery may be expected after the surgical operation if such accidents are avoided.

UROLOGY

Simple Renal Cysts in Children: Review of the Literature and Report of Five Cases. J. H. DeWeerd and H. B. Simon. J. Urol 75:912-921 (June) 1956 [Baltimore].

The present report is concerned with congenital simple (serous) cysts of the kidney occurring in childhood. Although these cysts are found fairly frequently at postmortem examination (2 to 4%), they rarely attain sufficient size to become clinically evident during childhood. Congenital simple renal cyst in children has been diagnosed clinically and treated in five patients at the Mayo Clinic since 1915. A table lists the important data on these five children and on 16 others described in the literature. All 21 patients met the following criteria: (1) the cyst was unilocular; (2) there was no communication between the cavity of the cyst and the renal pelvis; (3) the cavity of the cyst was lined with epithelium; (4) no renal elements were contained within the cyst; (5) a localized region of the kidney was involved; (6) the uninvolved renal tissue was relatively normal grossly or microscopically, or both, and (7) the renal pelvis and ureter were patent. Some cases included in previous studies were excluded from this study on the basis of these criteria.

Simple renal cyst is found somewhat more frequently in males and in the left kidney. It may be encountered at any age from the newborn period through adulthood, and it involves the poles of the kidney with approximately equal frequency. The presenting complaint in almost all cases is that of abdominal mass, occasionally accompanied by pain. The lesion is demonstrable by urography, either excretory or retrograde, but roentgenographic or clinical differentiation from embryonal carcinosarcoma (Wilms' tumor) is practically impossible. For this reason, and because simple renal cyst in children is rare as compared with renal embryoma (Wilms' tumor), the usual preoperative clinical impression is that of malignant disease. Excision of the presenting cyst wall is the treatment of choice unless severe destruction of renal parenchyma necessitates nephrectomy. Unfortunately, such destruction frequently prevails.

Urinary Tract Calculi in Poliomyelitis. J. R. Taylor, A. J. W. Alcock and J. A. Hildes. Canad. M. A. J. 75:29-34 (July 1) 1956 [Toronto, Canada].

A total of 1,390 patients with acute poliomyelitis were admitted to the Winnipeg Municipal Hospital during the three years from 1952 to 1954. Motor paralysis of the bladder, resulting in acute urinary retention, was a common accompaniment of low spinal paralysis. Approximately 300 patients required catheter drainage for varying periods of time for this reason Although complete detrusor paralysis was transient, return of bladder function often took several weeks and was sometimes incomplete, as shown by cystometrography carried out on a few of the patients. Initially, Zephiran (benzalkonium chloride) in a 1:20,000 solution was used as a bactericidal irrigant in patients with indwelling catheters, but on this regimen incrustations frequently formed on the catheter and sometimes became the nidus for bladder calculi. In nine patients, bladder calculi were crushed and removed transurethrally and in three patients suprapubic lithotomy was carried out. When "G" solution was adopted as a routine bladder irrigant, bladder calculi were effectively prevented from forming and a few already present were dissolved. A low-grade cystitis was common in patients with indwelling catheters, but this subsided once the catheter was removed.

Renal calculi proved to be the most important and the most troublesome of the urinary-tract complications in patients with poliomyelitis. Artificial respiration was necessary in 237 patients. Respirator treatment for less than 40 days was necessary in 74 patients and for long periods in 98. Renal stones developed in 33 (about a third) of those requiring long-term respirator treatment and in one of those receiving short-term respirator treatment. No renal stones were found in the group not treated in a respirator. As in patients with prolonged recumbency for any reason, the authors consider immobility, with resulting demineralization of bone, and hypercalciuria the major factors in the development of renal stones. The calculi were typical radiopaque recumbency calculi of the soft triple-phosphate type. They were usually multiple and often bilateral, but there were several instances of solitary calculi or of involvement of only one kidney with multiple calculi. The stones varied greatly in size, from minute particles to stones of up to 2 or 3 cm. in diameter.

Repeated x-ray examinations are necessary throughout the whole period of recumbency. Although the usual prophylactic measures must be modified on account of the dependence on artificial respiration and severe extensive lower motor neurone paralysis, increased activity, weight-bearing, high urinary output, restricted calcium intake, and control of gross infection are important prophylactic measures. Multiple small and moderately large stones will often pass spontaneously. Stones in the lower ureter can be removed by transurethral manipulation in spite of some difficulties in cystoscopy caused by contractures and stiffness of hips and knees. When surgery on the kidney or ureter is necessary, it can be carried out with relative safety and with good results. Seventeen operations for renal calculi were carried out in 16 patients.

The Surgical Spread of Cancer in Urology. P. Boreham. Brit. J. Urol. 28:163-175 (June) 1956 [Edinburgh, Scotland].

Boreham believes that three of the following four criteria should be satisfied if a metastasis is to be considered an implant: 1. It must be discontinuous with the primary tumor, and therefore cannot have arisen by direct extension. 2. The growth must arise in another direction than that of the lymph drainage of the primary tumor. 3. It must arise in a tissue not normally the seat of blood-borne metastases. 4. The metastasis should preferably be growing in a tissue foreign to the type cell of the tumor.

Six cases of recurrence of carcinoma of the bladder occurring in the urethra are presented. Three of these were in the posterior and three in the anterior urethra. Another five patients are presented in whom metastases developed in the prostatic cavity after a prostatectomy had been performed in the presence of a carcinoma of the bladder. Fifteen patients with recurrence of carcinoma of the bladder in the scar of an open operation are discussed. It was found also that after approximately 5% of open operations on the bladder the first recurrence was in the scar. Although the evidence that these metastases arose by implantation is not conclusive in all of the cases, it is quite clear that surgical implantation does occur and that in some cases a surgical implant is the only metastasis that spoils an otherwise curative operation.

Bladder Involvement in a Case of Herpes Zoster. M. Dales and G. Wilson. Brit. J. Urol. 28:198-200 (June) 1956 [Edinburgh, Scotland].

A 42-year-old man was admitted to hospital with retention of urine of 12 hours' duration. During the preceding week he had been confined to bed with an upper respiratory infection. Four days prior to admission a painful rash had developed over his right buttock and thigh, and for 24 hours he had complained of intermittent suprapubic pain and increasing difficulty in micturition. Pressure in the suprapubic region produced intense pain and increased his desire to micturate. The prostate and urethra were normal. A typical zosterian eruption was present over the right buttock and thigh in the areas of the first and second lumbar dermatomes. Catheterization was performed and produced 300 ml. of clear urine. A course of aureomycin was given for the herpes zoster. Retention of urine recurred after the initial catheterization. Closed, continuous catheter drainage was used for 48 hours, after which the patient voided urine normally. Six weeks after discharge the patient remained well and had had no further urinary symptoms. There was a slight brownish pigmentation over the area of distribution of the rash, but there was no sensory loss, no muscle wasting, and the reflexes were normal. This case differs from those described elsewhere in that the lumbar segments of the cord were involved and no vesicles were found in the bladder or urethra. The disturbance appears to have been primarily a motor dysfunction. Recorded cases of bladder involvement in herpes zoster are remarkably few, a finding which is surprising in view of the relative frequency of bladder dysfunction in similar virus diseases of the nervous system, such as poliomyelitis.

OPHTHALMOLOGY

Retinal Lesions in Hodgkin's Disease. M. Brihaye-van Geertruyden A.M.A. Arch. Ophth. 56: 94-99 (July) 1956 [Chicago].

The author was able to follow for three months the evolution of cotton-wool opacities in the retina of a 31-year-old woman with Hodgkin's disease. The lesions were first noticed when the patient entered the hospital during a febrile episode. During the following days, new spots developed. As soon as cervical and splenic x-ray therapy was begun the retinal lesions progressively faded and no new lesion appeared, but 18 days after the end of the treatment new white spots appeared with hemorrhages. The number increased until death. The histological examination at autopsy proved that the cotton-wool opacities were conglomerates of cytoid bodies in the nerve-fiber layer of the retina. Although cotton-wool opacities have been observed in many diseases, the author was unable to find any other report on their occurrence in Hodgkin's disease. In conclusion she stresses the following points: 1. Cotton-wool opacities do not necessarily represent an infiltration by the specific tissue of Hodgkin's disease. 2. No parallelism existed between the appearance of cotton-wool opacities and the degree of anemia, hepatic damage, or biliary-tract disease. The evolution of cotton-wool opacities closely followed the general condition of the patient. Ocular examinations of other patients with Hodgkin's disease might throw additional light on the pathogenesis of this curious lesion.

Some Ocular Sequelae of Tuberculous Meningitis: A Preliminary Survey, 1953-54. A. J. Mooney. Am. J. Ophth. 41: 753-768 (May) 1956 [Chicago].

With modern therapy (streptomycin, aminosalicylic acid, and isoniazid) the survival rate in tuberculous meningitis is now about 80% and, as a result of this, eye complications that were practically unknown seven years ago are now a frequent occurrence. Within the past 15 months the author has examined 65 patients with tuberculous meningitis, of whom 47, or 72%, had ocular lesions. The pathological process appears to be tuberculous arachnoiditis that causes either papilledema by interfering with the circulation of the cerebrospinal fluid or pale disks by strangulating the pial vessels going to the optic nerves and chiasma. There was no connection between the amount of intrathecally administered streptomycin and the eye manifestations. No relationship could be established between deafness and eye complications.

The author believes that choroidal tubercles can be regarded as evidence of miliary tuberculosis. As a result of studying 16 patients with choroidal tubercles, he formed the opinion that the tubercles are a valuable prognostic guide; new tubercles appear when the disease is active, but when pyrexia subsides no fresh tubercles appear. Many smaller tubercles disappear without leaving any ophthalmoscopic evidence.

Papilledema was present in 17 patients, in some of whom the edema was confined to the upper and lower disk margins and subsequently disappeared as the disease regressed. In other patients the swelling amounted to two or even three diopters and the papilledema in these seemed to be of two varieties. In the first variety the disk showed a pale serous-looking swelling not necessarily associated with a high cerebrospinal fluid pressure. This type of edema subsides as the disease is controlled, and improvement seems to be accelerated by repeated spinal punctures. The edema seems to be caused by external hydrocephalus, and the process is reversed as the meningitis subsides. In the second type of papilledema the disk presents the florid appearance typical of increased intracranial pressure from brain tumor or internal hydrocephalus. Antibiotics and repeated spinal punctures fail to control the swelling, and the author believes that papilledema of this type may go on to secondary atrophy if steps are not taken in time to relieve the increased intracranial pressure. Apparently the tuberculous basal meningitis causes adhesions in the posterior fossa that obstruct the flow of the cerebrospinal fluid from the fourth ventricle into the cisterna magna with resulting internal hydrocephalus. Neurosurgery was carried out in four of these patients.

Pallor of the disks with clear margins was present in 13 of the patients. Eight of these 13 patients were transferred to the neurosurgical unit for exploration of the optic nerves and chiasm in the hope of finding adhesions interfering with the blood supply of this part of the visual pathway, the removal of which would either improve the vision or prevent it from getting worse. The need for neurosurgery seems to be influenced to some extent by the time that has elapsed before treatment is instituted. When a practitioner is in doubt about diagnosis in a case of this nature, the patient should be sent immediately to a suitable hospital for treatment. A short course of cortisone therapy (in the absence of serious pulmonary complications) should be started and continued for about three weeks, with a view to preventing the formation of adhesions. A long course is not justified. If this treatment fails to prevent papilledema or pale disks, a careful watch should be kept on the disks, and, if they deteriorate in spite of treatment, neurosurgery seems justified.

igmentary Retinal Lipoid Neuronal Heredodegeneration (Spielmeyer-Vogt Disease): The Neuro-Ophthalmologic Considerations. J. Hoffman, Am. J. Ophth. 42: 15–21 (July) 1956 [Chicago]

The identification of many neurological disorders is facilitated by ophthalmoscopic examination. One entity that exemplifies this fact is Spielmeyer-Vogt disease, which is also known as Batten-Mayou disease, juvenile Tay-Sachs disease, juvenile amaurotic family idiocy, and cerebromacular dystrophy. On the basis of intensive research and critical analysis of the numerous papers on the subject as well as of independent clinical and laboratory studies, Hoffman and his co-workers believe that Spielmeyer-Vogt disease is a separate entity, distinct from not only the systemic lipoidoses but also the infantile type of Tay-Sachs disease. The differences far exceed the resemblances, which are superficial at best. Clinically, Spielmeyer-Vogt disease is manifested by an heredofamilial predisposition as a Mendelian recessive. About the fifth to eighth year of life there are suggestive symptoms indicating visual impairment. After an intellectual arrest, there is an almost precipitous drop. Organic psychological changes, such as irritability, apathy, and speech abnormalities, accompany this decline and are associated with numerous indications of a deteriorating central nervous system. Upper and lower motor neurone palsies, with or without grand mal and/or Jacksonian convulsions, are observed in varying combinations. One of the earliest changes observable on ophthalmoscopy is a yellowish-gray appearance of the retina, with slightly narrowed blood vessels. Gradually, small pigmented granules make their appearance at the periphery and in the course of time proceed centrally, eventually giving the entire retina an appearance resembling that in retinitis pigmentosa. Shortly after these changes have begun to show up, a macular alteration is noted and with it an expanding central scotoma. In sharp contrast to the "cherry-red spot" macula of Tay-Sachs disease, in Spielmeyer-Vogt disease there is a central brownish, brick-red core at the macula region. This is surrounded by a pale ring and then a halo of peppery pigmentation. The disk itself becomes extremely pale and presents a primary atrophic picture only late in the progress of retinal alterations.

The histories of two sisters with so-called Spielmeyer-Vogt disease are presented. The author suggests that a more appropriate, accurate, understandable, and meaningful name for this entity would be "lipoid neuronal pigmentary retinal heredodegeneration." It would eliminate the proper name confusion (Spielmeyer-Vogt, Batten-Mayou, Stengel, and so forth). It would separate this disease entity from the group of amaurotic family idiocies, since, technically speaking, it is a dementia rather than an amentia, as implied by the term idiocy. This new name would also do away with the limitation of the incomplete term "cerebromacular dystrophy." The name suggested indicates that the disease is a degenerative process of a hereditary nature and involves the neuronal elements and is associated with an inclusion lipoidal deposit. It presents another distinguishing feature, namely, the involvement of the pigmentary as well as the neuronal elements of the retina.

THERAPEUTICS

The Chemotherapy of Hypertension. R. Birchall, G. F. Weber and H. M. Batson. Am. Pract. & Digest Treat. 7:1104-1110 (July) 1956 [Philadelphia].

The results of the use of the newer chemotherapeutic agents in the treatment of 81 closely followed patients with various types of hypertension were evaluated in an effort to form definite impressions as to the usefulness of these preparations. The drugs employed included hexamethonium, hydralazine, veratrum, the derivatives of rauwolfia serpentina, and the newer ganglionic blocking agents, ansolysen and ecolid. Results were intentionally not evaluated on the basis of statistical analysis. Subjective as well as objective improvement and consideration of the emotional response of the patient to each regimen were the bases of evaluation. All patients with malignant hypertension or severe essential hypertension should be hospitalized for careful regulation of the blood pressure by the administration of a combination of a ganglionic blocking agent and reserpine. They should be taught to take their own blood pressures at home and to regulate the dosage of the ganglionic blocking agent by means of a sliding scale, depending on the blood-pressure reading taken at intervals that vary with the particular ganglionic blocking agent used. In patients with malignant hypertension, the blood pressure can almost always be controlled and the course of the disease "reversed" if renal function is good and the blood urea nitrogen level is below 40 mg. per 100 cc.

The authors have all but abandoned use of hydralazine, since it seems to have little advantage over reserpine and is more toxic. The toxic level of veratrum is so close to the therapeutic level that it is rarely considered useful. The effect of the rauwolfia derivatives is unpredictable. In patients who have previously had bilateral sympathectomy, they are potent antihypertensive agents and must be given cautiously and in small dosage initially. Of the ganglionic blocking agents, ansolysen is no more effective than hexamethonium, but the side-reactions are fewer and the regimen considerably easier. Ecolid has recently proved to be just as effective as ansolysen and will replace it as the agent of choice because of its smoothness of action and the convenience of administration at roughly 12-hour intervals as opposed to the ansolysen schedule, i. e., before meals and at bedtime. Experience with inversine is still too limited to permit any decision as to whether or not it will prove superior to ecolid.

Pharmacological and Clinical Research on O-Acetylsalicylamide. O. Piccinelli and A. Fiocchi. Gaz. med. ital. 115:139-146 (May) 1956 (In Italian) [Turin, Italy].

The authors carried out pharmacological and clinical research on O-acetylsalicylamide. The drug has no toxic effects, it is easily tolerated, and it has a marked corticotropic effect. One hundred forty-eight patients with rheumatism, fever, and various pains were treated with the drug. Dosage varied from 1 to 2 gm per day given orally in divided doses of from 0.1 to 1.5 gm at a time. Tolerance was perfect. Large doses caused some drowsiness. Gastric tolerance was very good, even in patients with gastrointestinal affections. Blood pressure remained within normal values. There were no kidney complications. Results were good in five patients with rheumatism. With daily doses of from 10 to 12 gm. fever disappeared within four to seven days. Results were not so good in 8 patients with rheumatic arthritis. In some patients symptoms were attenuated, but radiological observation did not show any improvement. Ten patients with muscular rheumatism recovered completely. The drug has a marked analgesic effect. Neurological affections were checked in one or two days. The antipyretic effect was poor in six cases of typhus and two cases of brucellosis. The effects were good in 11 cases of pleuropulmonary affections: both symptoms and fever were checked.

Clinical and Laboratory Studies of Novobiocin, a New Antibiotic. W. M. M. Kirby, D. G. Hudson and W. D. Noyes. A. M. A. Arch. Int. Med. 98:1-7 (July) 1956 [Chicago].

Laboratory studies of novobiocin, a new antibiotic, showed that micrococci (staphylococci) were remarkably sensitive to the drug in vitro and there was no cross resistance with other antibiotics. Pneumococci and group A streptococci were also inhibited by low concentrations of novobiocin, but they were less sensitive than micrococci. Among the gram-negative bacilli, members of the Proteus group were moderately sensitive. Novobiocin was less effective in the presence of a larger inoculum of bacteria, and serum exerted a pronounced inhibitory effect. Concentrations of novobiocin in the serum of patients receiving 2 gm. of the drug daily were considerably higher than those obtained with other antibiotics, but these levels were determined by a serial dilution method in broth and did not reflect the factor of serum inhibition.

Thirty-five patients with bacterial pneumonia, 26 with micrococcic infections, 3 with streptococcic infections, and 11 with miscellaneous conditions were treated with novobiocin. The daily dose was 2 mg., administered orally. Results in the 75 patients were generally favorable, and they appeared comparable to those obtained with erythromycin. Side-effects were minimal. Maculopapular rashes, which may have been caused by novobiocin, developed in two patients. In five patients with micrococcic wound infection and abscesses, prompt healing did not occur and the infecting organisms rapidly became resistant to novobiocin. For this reason, it is recommended that novobiocin be used exclusively for the treatment of infection caused by organisms resistant to other antibiotics, such as penicillin, streptomycin, and the tetracyclines. Wherever possible, another antibiotic to which the pathogenic agent is also sensitive should be administered simultaneously in an attempt to prevent or delay the emergence of antibiotic-resistant micrococci.

The Treatment of Chronic Granulocytic Leukemia with Myleran. I. G. Early and R. W. Prichard. North Carolina M. J. 17:315-319 (July) 1956 [Winston-Salem, N. C.].

Myleran is a drug of relatively recent origin that has been found to have a beneficial effect on the course of chronic granulocytic leukemia. It consistently produces a decrease in the number of circulating granulocytes, probably by depressing granulopoiesis. In excessive doses, however, it may cause a decrease in other formed elements of the blood. Thus the chief toxic manifestation is thrombocytopenia. The drug has been shown to be of no benefit in other types of leukemia or in the myeloblastic phase of chronic granulocytic leukemia. Twelve patients with chronic granulocytic leukemia were treated with Myleran in doses of 4 to 12 mg. per day until an adequate effect had been obtained. Good to excellent responses were obtained in seven patients, with remissions lasting up to 13 months. Three patients who had leukopenia, thrombocytopenia, or both were not benefited appreciably by the drug. In patients who responded favorably the first improvement was in the sense of well-being. This was followed by a gradual fall in the leukocyte count, especially in the number of immature granulocytes, together with a rise in the hemoglobin level and a gradual decrease in the size of the spleen. In three patients immature granulocytes completely disappeared from the peripheral blood. After the drug was withdrawn, the total leukocyte count ordinarily started to rise again within from one to eight months. The remaining five patients died. Their survival periods ranged from 1½ to 15 months after the start of therapy. Two of these patients had excellent remissions initially; one also responded well to second and third courses of Myleran, but both subsequently died in myeloblastic relapses. One patient had a minimal response initially but then had a myeloblastic relapse while receiving the drug. Most observers now agree that the method of choice for the administration of Myleran is to give small doses until the desired response is obtained. The advisability of giving maintenance doses after a remission has been induced has not yet been determined. It is not known whether the use of maintenance doses hastens the development of resistance. The one patient in this series on maintenance therapy has done quite well over a period of 13 months. The possibility of a carcinogenic effect should be kept in mind when patients are being treated with this drug. Myleran seems to produce a greater and more consistent response than other drugs used in the treatment of this disease. It is more easily administered than roentgen therapy and has been found to produce good remissions in some patients who have shown little or no response to irradiation.

Clinical and Experimental Researches on a New ACTH Combination with Prolonged Effect. L. Rosa, G. Bergami, A. Bersani and others. Riforma med. 70:641-645 (June 9) 1956 (In Italian) [Naples, Italy].

The authors studied the effect of corticotropin (ACTH) combined with a phosphate of polyphloretine (AH 51). Local metabolism of ACTH was considerably delayed. The effect of a dose of 20 I. U. per day on 10 patients with asthma lasted 24 to 48 hours. Maintenance dose was 5 I. U. A high dose of 30 I. U. had an effect for three or four days on three patients with urticaria. Eosinophilia dropped to about 50%. The eosinopenic effect lasted from 72 to 96 hours. The administration of one dose of the drug increased the elimination of the 17-ketosteroids. The effects of this new ACTH combination last four times longer than those of plain ACTH for beginning doses; they last eight times longer for maintenance doses. The combination was well tolerated and did not cause side-effects.

PATHOLOGY

Electron Microscopy of the Leprosy Bacillus: A Study of Submicroscopical Structure. E. M. Brieger and A. M. Glauert. Tubercle 37:195-206 (June) 1956 [London, England].

Mycobacterium leprae and Myco. tuberculosis are indistinguishable in preparations stained by the Ziehl-Neelsen technique. Conclusions drawn from electron micrograms of unsectioned bacilli may be deceptive unless the evidence is supplemented by examination of ultra-thin sections. Since sectioning has given information of a submicroscopic structure in ordinary bacteria, it was hoped that by applying this technique to the study of Myco. leprae it would be possible to decide whether the differences seen in electron micrograms of unsectioned mycobacteria are due to genuine differences in internal organization. It was also thought that the technique of ultra-thin sectioning might give information on the structure of the "globi" or lepra cells, which have been the subject of so much controversy. It was planned to compare the intracellular growth of the leprosy bacillus with that of the tubercle bacillus, which had been studied previously.

Material from six patients with lepromatous lesions and from three with the tuberculoid or macular type of leprosy was obtained at a leprosarium in the Belgian Congo. Tissue juices were embedded in agar and fixed in osmic acid. They were transported to England by air in a 70% alcohol solution and then embedded in methacrylate. Punch biopsies were prepared in the same way. Electron micrograms of leprosy bacilli confirmed observations made on stained preparations, which have shown that the morphological appearance of these organisms varies. The bacilli seen in electron micrograms range from short bipolar rods to filaments of different thickness and density; dense spherical forms are also seen. The relationship of these forms to one another cannot be ascertained from a series of fixed preparations. Nevertheless, if the pleomorphism that is observed is not due to degeneration, the leprosy bacillus must have a complex life history. The leprosy bacilli of the tissue juices occurred as isolated filaments and rods and as groups of organisms or "globi."

There has been considerable speculation concerning the structure of the "globi." According to Denney, four different interpretations have been given. Some observers have considered them to be intercellular colonies; others have considered them to be clumps formed within lymph spaces, mechanically compressed into spherical or spheroidal forms; still others have expressed the opinion that the masses represent colonies of individual rods bound together as a zooglea. A fourth view is that they may be characteristic colonies growing within an as yet unidentified membrane. Denney himself agrees with the last view. Chaussinand distinguishes between an "amas," or "mass," and a "globus." In the mass the bacilli are still distinguishable as individual organisms. In the globus the bacilli lie end-to-end, in parallel array, and are so tightly packed that it is no longer possible to distinguish them from one another.

The electron micrograms also show groups of bacilli contained within a limiting membrane that are similar to the globi described by Denney. The nature of this membrane cannot be deduced from the electron micrograms, but the possibility that it is the cell membrane of a disintegrating leukocyte cannot be disregarded. Denney believes that the membrane restrains the growth of the bacilli and Chaussinand refers to the membrane as a capsule and agrees that it prevents the spreading of the rapidly multiplying organisms. It is impossible to judge from electron micrograms whether the bacilli within these clumps are viable, although some have the density of apparently healthy organisms. Under the electron microscope the bacilli confined within these membranes are still distinguishable from one another. The findings reported in this paper are only preliminary. The study was limited to obtaining evidence of the value and possibilities of applying to the problems of leprosy techniques that had already proved valuable in the field of tuberculosis research.

The Failure of Increased Intravascular Pressure to Induce Arterial and Arteriolar Necrosis. D. G. Johnston and G. A. Marples. Angiology 7:279-286 (June) 1956 [Baltimore].

The causative relationship of necrotizing vascular lesions and hypertension has long been a subject of speculation and debate. Opinions regarding the pathogenesis of acute vascular disease in hypertension can be grouped into three general categories: (1) effects of increased intravascular tension on vessels as the chief factor; (2) effects of increased intravascular tension and toxic substances in the blood resulting from renal insufficiency and/or renal ischemia as necessary factors; and (3) effects of toxic substances alone. Investigators and clinicians are accepting more frequently the idea that, in hypertension, arterial and arteriolar necrosis are caused principally, if not solely, by the effects of increased intravascular pressure. The most vigorous proponents of this idea have been Byrom, Dodson, and Wilson. In the experiment of Byrom and Dodson, the major portion of the arterial system was subjected to mechanical stretching of the wall by the forceful injection of fluid.

The present authors decided to subject a small part of the arterial system to rapidly increased intravascular tension. The immediate recipients of the acute hypervolemia, in this experiment, were one or both renal arteries, via a short segment of aorta. Ninety adult male albino rats of Wistar strain were used. Ten of these were controls. It was found that acute necrosis of renal arteries and arterioles could not be caused by sudden severe increases of intra-aortic pressure in the region of the renal ostia. These experiments do not support the "vicious circle" theory of Wilson and Byrom and their contention that necrotizing vascular damage is the direct result of hypertension.

Secondary Amyloidosis in Leprosy. J. S. Shuttleworth and Sister Hilary Ross. Ann. Int. Med. 45:23-38. (July) 1956 [Lancaster, Pa.].

Secondary amyloidosis is the leading cause of death from leprosy in the National Leprosarium of the United States. The primary purpose of the studies described was to find a method of diagnosing amyloidosis at an earlier stage than is possible with the Congo red test. The first approach was to correlate Congo red findings with clinical and autopsy material. The next step was the study of serum protein patterns in kown cases of amyloidosis parallel with controls in an effort to find a consistent pattern that might be of assistance in determining which patients have or will have amyloidosis and also to study the effect of large doses of hyaluronidase on the serum protein pattern, proteinuria, and hepatosplenomegaly in amyloidosis. A third, very limited, study was to obtain liver biopsy specimens with the Vim-Silverman needle in cases of known amyloidosis (as evidenced by the Congo red test) and in cases in which amyloidosis was not apparent. The Congo red test was performed on 95 patients in various stages of leprosy. Eight of these had the tuberculoid and 87 the lepromatous type of leprosy. In some of the patients the test was repeated at intervals of a year. The Congo red was given intravenously in a 1% aqueous solution in dosages of 1 cc. of the solution per 10 lb. of body weight. Blood specimens were collected at the end of two minutes and one hour after the injection, the two-minute specimen being used as the control. Urine specimens were examined for Congo red one hour after the administration of the dye. Laboratory studies ascertained the nonprotein nitrogen content of the blood, the total serum proteins; serum albumin; globulin; alpha, beta, and gamma globulins; serum cholesterol; phospholipids; polysaccharides; *mucoproteins*; and the function of the liver by the thymol-turbidity and cephalin-cholesterol–flocculation tests. Urinalysis consisted of specific gravity, quantitative albumin, sugar, and microscopic examinations. Serum polysaccharides were determined by the tryptophan reaction and expressed as Coleman units. Mucoproteins were determined by the method of Winzler and others.

The authors record and comment on the results of the various tests and conclude that amyloidosis of the kidney, which occurred in all of the patients, is the direct cause of death. The diagnosis of this complication depends largely on the development of a persistent proteinuria, Congo red absorption, hepatosplenomegaly, and, to a lesser degree, altered serum proteins and perhaps liver biopsy in selected cases. The correlation between the Congo red test and the degree of amyloidosis is poor, and unless this test shows 80 to 100% dye absorption in one hour the diagnosis cannot be made from this finding alone. Serum protein and lipoid changes occur in lepromatous leprosy per se, and in a study of the various protein fractions no consistent alteration occurred in cases of leprosy complicated by amyloidosis. The average duration of life after the onset of proteinuria in amyloidosis was 38.33 months, with a fairly wide range above and below this figure. The development of anemia and a progressive elevation of the nonprotein nitrogen are unfavorable prognostic signs

The Treated Pulmonary Lesion and Its Tubercle Bacillus: I. Pathology and Pathogenesis. W. E. Loring and H. Mac Vandiviere. Am. J. M. Sc. 232:20-29 (July) 1956 [Philadelphia].

The classic lesion of pulmonary tuberculosis has undergone significant qualitative and quantitative changes as a result of treatment with the modern chemotherapeutic agents. The authors demonstrate this on the basis of observations made in their laboratory on 69 surgical specimens obtained in 11 pneumonectomies, 1 bilobectomy, 24 lobectomies, 28 segmental resections, and in 5 operations combining lobectomy with segmental wedge resection. Studies on these specimens and reports by other observers indicate that the morphological alterations produced by the administration of streptomycin differ from those that result after treatment with isoniazid. The authors describe first the morphological modifications of the classic tuberculous lesion caused by streptomycin and then those produced by isoniazid. They suggest that these changes are probably determined by two different factors: (1) the site of action of the drug with respect to the individual cell, and (2) the action of the drug on the fundamental metabolism of the bacillus. Streptomycin and isoniazid are capable of attacking the tubercle bacillus directly. They materially aid in the prevention of multiplication and slow down metabolic processes, and isoniazid even permits destruction of the bacillus. The pathological evidence presented in this report is indirect. The bacteriological findings described in the report following this one contribute further valuable data

The Treated Pulmonary Lesion and Its Tubercle Bacillus: II The Death and Resurrection. H. Mac Vandiviere, W. E. Loring I. Melvin and S. Willis. Am. J. M. Sc. 232:30-37 (July) 1956 [Philadelphia].

This second report is concerned with two problems. The first concerns the autonomous or drug sterilization, or both, of the tuberculous lesion. The second problem concerns the modification of viable bacilli. Several workers have found lesions within the human body to contain microscopically visible acid-fast bacilli that do not grow on culture mediums. Since this phenomenon was observed prior to the advent of antituberculous drugs, it cannot be assumed that drugs are solely responsible for this nonculturable status of visible bacilli. Opinions are divided as to whether these organisms are alive or dead. The authors made bacteriological studies on pulmonary tissues obtained in the surgical treatment of 84 patients with tuberculosis. These tissues contained 48 open cavities, 26 closed cavities, 17 end-stage cavities, and other lesions. All patients had received combined chemotherapy for varying periods. When materials from 48 open cavities were placed on culture mediums, growth resulted in the usual period of less than eight weeks in 44 of them. One culture required three months to grow. The cultures were, in general, resistant to one or another of the major antituberculous drugs. From 22 closed cavities, no bacilli grew on culture within the usual eight-week period. In nine instances, however, cultures grew after extended incubation of from 3 to 10 months. Bacilli were found microscopically in 9 of 17 end-stage cavities, but when material from these cavities was placed on culture mediums, there was no growth, even after extended incubation.

Thus it has been demonstrated by bacteriological and pathological (preceding paper) data that in certain lesions tubercle bacilli may be disposed of. This allows the normal body mechanisms and physicochemical status to produce the end-stage cavity. The closed cavity with its hibernating bacilli is apparently the result of normal body mechanisms with little drug effect becoming manifest within the cavity. It was in this type of lesion that extended incubation demonstrated its greatest value by increasing the propagability of the latent bacilli. A high percentage of the classic open cavities revealed rapid growth and the bacilli were generally resistant to drugs. These are interpreted as drug failures insofar as the cavity and its bacilli are concerned.

The authors believe that the whole story is not known, and that, if further enzymes or further improvements of techniques are introduced, more of these bacilli thought "dead" may actually be found to be alive. One type of lesion (closed cavities) has revealed bacillary life where viability was doubtful. There may be other instances yet unknown. There are still bacilli that can be seen but that do not grow with this technique. What will happen to them in the body? Will modified environmental conditions bring them to life? What is the future fate of these adapted tubercle bacilli?

Electron Microscopy of Poliomyelitis Virus. A. R. Taylor and M. J. McCormick. Yale J. Biol. & Med. 28:589-597 (June) 1956 [New Haven, Conn.].

Concentrated poliomyelitis virus preparations containing essentially one type of particle have been obtained consistently from infectious tissue culture fluids by means of a combination of alcohol precipitation and centrifugation. The ultimate size and shape of small virus particles as they are seen in shadowed electron micrographs appear to be dependent upon the hydration of the particles at the time of the first exposure to high vacuum. The authors describe a method for the preparation of electron microscope specimens, in which the collodion membranes are formed on agar blocks, used as filtration membranes for the samples, and subsequently mounted on specimen screens for examination. The use of collodion as a filtering membrane for the preparation and mounting of small pathogenic viruses for electron microscopic examination has distinct practical advantages. The equipment is simple and easily sterilized. The viruses may be handled in saline solutions avoiding the drastic osmotic effects of water and nonisotonic salt solutions. The studies described led to the hypothesis that the characteristic particles of poliomyelitis virus, approximately 30μ in diameter, are "cell-like" structures containing a central body approximately 20μ in diameter and a surrounding membrane.

RADIOLOGY

Bronchial Carcinoma: Effect of Radiotherapy on Survival. J. R. Bignall. Lancet 1:876-879 (June 9) 1956 [London, England].

The survival of 207 patients treated by radiotherapy is compared with that of 248 who were not so treated. Of the 207 patients who received radiotherapy, 114 were given an estimated tumor dose of 1,000 to 3,900 r and 93 were given 4,000 r or more. The group that was irradiated and the group that was not irradiated were as far as possible alike in the factors known to influence survival. No patient was known to have extrathoracic metastases when the decision concerning treatment was made. The greatest difference between the treated and the untreated in duration of life from first attendance at hospital was found in those without mediastinal metastases treated with 4,000 r or more: 35% lived a year and 15% two years, compared with 24% and 6% of the untreated. In the patients with mediastinal metastases the differences were less; and the pattern of survival of those treated with 1,000 to 3,900 r was almost identical with that of the corresponding untreated group. There is suggestive evidence that the differences were not due entirely to the variations in selection and random-sampling but were contributed to by the radiotherapy. It is unlikely, however, that radiotherapy caused an increase of as much as 10% in the proportion surviving a year after diagnosis or 5% in those living two years, even in the most favorable cases treated with the higher doses.

Carcinoma of the Posterior Tongue Treated with Radiation. C. L. Marin and J. A. Martin. Radiology 66:835-841 (June) 1956 [Syracuse, N. Y.].

In the period from 1936 to 1950 a total of 120 patients with primary carcinoma of the tongue were seen at a clinic in Dallas, Texas. Forty of these, or 33.3%, had lesions involving the posterior third of the tongue, and they represent the material for this study. Men outnumbered women, roughly two to one. Most patients were in the age range between 50 and 80 years. All patients were treated primarily with irradiation, employing low-intensity radium needle implantation of the primary tumor. Adequate atropinization and local anesthesia are imperative if one is to obtain good access to the posterior tongue for radium needle implantation. As a rule, lesions located in the true base of the tongue are treated by the vertical implantation of needles containing 2.4 mg. of radium distributed in 4 cm. of active length. Tumors on the posterior lateral border and extensions into the floor of the mouth and sides of the pharynx are implanted with needles containing 1.33 mg. of radium in 1.5 cm. of active length. Patients are hospitalized while the radium is in place. Twenty-two of the patients had lymph node metastases. These were treated by interstitial radium implants combined with heavily filtered x-ray therapy with conventional 220-kv. equipment. The over-all five-year salvage rate was 38%. Ten of the 18 (56%) without palpable nodes survived, but only five of the 22 (23%) with involved lymph nodes survived. Radical surgery was never employed as the primary treatment, but secondary surgery was used for removal of sequelae in a few cases. No block dissections were done. The results obtained compare favorably with a salvage of 33% obtained for a group of 120 cancers involving all portions of the tongue treated with a similar technique.

Ultrasoft Roentgen Rays in the Treatment of Hemangiomas: A Follow-Up Examination of 400 Cases of Strawberry Marks and Port-Wine Stains. E. Amdrup and G. Knudsen. Radiology 66:825-834 (June) 1956 [Syracuse, N. Y.].

Four hundred two hemangiomas in 339 patients were treated in the Department of Radiology of the Town and County Hospital, Kolding, Denmark, during the years 1940 to 1952. Three hundred fifteen of these were elevated, while the remaining 87 were flat. The flat hemangiomas in this series were port-wine stains. No cases of purely cavernous hemangioma (the subcutaneous, easily compressible tumor imparting a bluish appearance to the skin) were observed. All of the elevated hemangiomas treated were strawberry marks; these may be purely superficial or may contain a deeper, presumably cavernous element. No distinction between these two types was made in the present study. Histologically, both strawberry marks and port-wine stains are classified as capillary hemangioma, but while the elevated lesions reveal a poorly differentiated endothelium, the cells of the flat hemangioma are of adult type. This explains the considerably higher radiosensitivity of the strawberry marks.

Up to 1945 the tube used was one giving a beam with a half-value layer of 2.02 mm. of skin at 30 kv. and of 1.15 mm. of skin at 20 kv. Most elevated hemangiomas were treated at 30 kv., while the thinnest strawberry marks and flat hemangiomas received the softer radiation. Since 1945, the authors have used a tube with a beryllium window, with a focus-skin distance of 10 cm. A few hemangiomas were treated with Bucky rays, usually in fractionated dosage, with 500 r at each sitting. Except in these few cases, a large single dose was given. At present, the authors invariably use a single dose of 800 to 1,200 r. The adjacent unaffected skin is protected by a thin shield of lead foil, 0.1 to 0.3 mm. in thickness, which is sufficient to stop the beam of ultrasoft rays. Flat hemangiomas are irradiated without compression; elevated hemangiomas must be compressed during the exposure. Otherwise the abundant amounts of blood present in these lesions will absorb a large proportion of the ultrasoft rays, resulting in an undue difference in the dose delivered to the surface and that reaching the deeper portions. The therapeutic results in 315 strawberry marks were excellent in 212, good in 74, and unsatisfactory in 27 lesions. In the port-wine stains the results were excellent in 42, good in 25, and unsatisfactory in 19 lesions. The authors conclude that ultrasoft rays are suitable for the treatment of both flat and elevated hemangiomas. They may be applied to all superficial hemangiomas, irrespective of their location. The technique is simple and the administration rapid, requiring a few seconds up to a few minutes. This is an advantage, especially in the case of a young, restless child.

ANESTHESIA

Phantom Limb Pain Associated with Spinal Analgesia. R. A. L. Leatherdale. Anaesthesia 11:249-251 (July) 1956 [London, England].

A 63-year-old man with a history of intermittent claudication over the past five years had had a midthigh amputation of his right leg, the clinical picture in that leg at that time being almost identical with the one now presenting in his left. Two weeks prior to the amputation of his right leg a right lumbar sympathectomy had been performed in an unsuccessful attempt to save the limb. For about three months after the amputation he had experienced phantom limb pain of a burning character in his right foot, but this had never been severe and had long since disappeared completely. When a midthigh amputation of the remaining (left) leg became necessary, a spinal anesthetic was injected into the subarachnoid space, with the patient lying on his left side. The patient was turned into the supine position immediately after the injection, and coincident with the onset of anesthesia he experienced severe phantom limb pain in his right (i. e., absent) foot and toes. It was far more distressing than any similar pain that had occurred after his first amputation.

Spasms of pain in the phantom limb continued throughout the duration of the analgesia, but, as the latter wore off, the sensations subsided. The relief of pain was almost as dramatic as its onset, and there was no recurrence during the four weeks the patient was in hospital. Examination of the stump of the right leg showed a well-healed amputation scar with no tender areas or palpable masses. He died shortly after discharge from a coronary thrombosis.

Hypothermia in the Repair of Interatrial Septal Defects at the State University of Iowa. J. L. Ehrenhaft and J. Moyers. J. Iowa M. Soc. 46:456-461 (Aug.) 1956 [Des Moines].

Twenty-three patients with interatrial septal defects were subjected at the department of surgery of the State University of Iowa to open cardiotomy with the aid of hypothermia. Eight patients had ostium-primum defects in which the lower border of the defect was formed by the rim of fibrocartilaginous tissue at the junction of the mitral and tricuspid valves. The remaining 15 patients had ostium-secundum defects, the margins of which were formed by a complete rim of fibromuscular septal tissue. In 10 of the 15 patients, ostium-secundum type defects were uncomplicated by other lesions. Cooling was accomplished by immersion in ice water. Rectal temperature was constantly recorded by a specially designed thermocouple and recording apparatus. Since there is a further temperature drop of 5 or 6 C after the patient has been removed from the ice bath, the patients were taken from the immersion tub when rectal temperatures had reached 33 C. The lowest resultant temperature was usually 27 C. To restore normal body temperature, reimmersion in warm water (48 C) was necessary at the end of the operation The anesthetic agent used in all patients was diethyl ether. Premedication consisted of morphine and scopolamine. Induction with nitrous oxide was followed by administration of increasing concentrations of ether until orotracheal intubation could be accomplished. Thereafter, ether concentrations were decreased as cooling progressed, so that almost all patients were given only nitrous oxide and oxygen when their body temperature was below 32 C. Apparently, the combined effects of morphine, nitrous oxide, and hypothermia met the surgical requirements

The best results were obtained in patients over 5 years of age who had ostium-secundum defects and only moderately elevated pulmonary artery pressures. Older patients up to the age of 48 who were subjected to surgical exploration and closure of the defects also made remarkable recoveries. Two of the 15 patients with ostium-secundum defects died. Of four patients in whom closure of an ostium-primum defect was accomplished only one survived; the other three died of cardiac failure during the operation or in the postoperative period. The authors' experience in the correction of interatrial septal defects with the aid of hypothermia supports the contention by other workers that open cardiotomy and direct suture in a bloodless field constitutes a good and a relatively safe method. Hypothermia has been found practical and not particularly hazardous to patients having correctable defects. Ventricular fibrillation occurred in 11 of the 23 patients, most commonly after the septal defects had been closed and at the time that circulation was reestablished If ventricular fibrillation occurred, cardiac resuscitation and conversion to ventricular rhythm and occasionally to sinus mechanism were accomplished in all but two patients by manual compression of the heart and often-repeated electric defibrillation. In two patients with irreparable lesions and pulmonary hypertension, death took place on the operating table.

PUBLIC HEALTH

Certain Aspects of the Microbiology of Frozen Concentrated Orange Juice. E. R. Wolford. Am. J. Pub. Health 46:708-715 (June) 1956 [Albany, N. Y.].

Coliform bacteria are widely distributed in nature. It has been the experience of the citrus product industry that it i impossible to produce frozen concentrated orange juice that is always free of coliform bacteria. The fact that coliforms have been found in orange juice products by most investigators has led to several studies of their source and significance in citr products. Patrick found coliforms to be associated with so insects, fruit flies, and slightly decomposed or damaged fr No Escherichia coli was found, but in a later study of cult isolated from frozen concentrated orange juice, Patrick f d that Esch. coli made up an appreciable proportion of the cultures. Hays and Riester found that oranges irrigated with raw lake water may frequently harbor Esch. coli.

Further investigations of sources and possible significance of coliforms in citrus products are reported here by Wolford He presents evidence to show that the presence of coliform bacteria in frozen concentrated orange juice does not necessarily indicate that direct contamination has occurred, coliforms were isolated from fruit aseptically picked into sterile bags, and this fact indicates that some coliforms are among the normally occurring flora in the groves. Esch. coli was isolated from oranges being delivered to concentrate plants; hence the presence of this organism in frozen concentrate need not indicate insanitary practices at the product plant. Packing house wash-tank solutions were found to contain many coliforms, including Esch. coli, and thus may be one of the principal sources of the organism in frozen orange juice products. Surface contamination of fruit-handling equipment was most common where bits of orange pulp had accumulated. Juice and concentrate samples, when positive for coliforms, appeared to reflect the condition of the fruit used rather than sanitary conditions of the juice line. The majority of coliform-positive samples contained l than 10 coliforms per 100 ml.

BOOK REVIEWS

The Lung as a Mirror of Systemic Disease. By Eli H. Rubin, M.D., Professor of Clinical Medicine, Albert Einstein College of Medicine, Yeshiva University, New York. Cloth. $12.50. Pp. 288, with 92 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1956.

This volume alerts the physician to the wealth of information in an x-ray examination of the chest. The lung serves as a mirror of changes in the organs and tissues of the body not accessible to direct examination. About 80 diseases may be associated with the pulmonary lesions described. Though roentgenography is stressed, the differential features of each disease are considered. The pulmonary lesions are described in the light of the physical and laboratory findings, and an effort is made to present the entire disease as mirrored in the chest film. This film assumes increasing importance as a case-finding tool, not only in detecting the pneumonias, tuberculosis, neoplasms, and other primary pulmonary diseases but also in detecting pulmonary manifestations of skin diseases, hemopoietic diseases, metabolic disturbances, and other disorders in the subspecialties of internal medicine. Even surgical abdominal diseases may show evidence of their presence in the chest film. Without adequate appreciation of the primary disturbance, the significance of the shadow may easily be missed. A number of rarities that may become commonplace with more frequent recognition are included. Though roentgenography and its modalities occupy a key position in chest diagnosis, a history, thorough physical examination, and the necessary laboratory tests, including bronchoscopy, bronchography, and, when indicated, lung biopsy, are essential to a diagnosis. With experience, a particular disease may be suspected or diagnosed with a high degree of accuracy by the roentgenographic findings alone. A definitive diagnosis always requires confirmatory evidence. Broadly speaking, pulmonary diseases may be grouped as primary, secondary (emboli, metastatic malignancies, and terminal pneumonias), and concomitant. If the lungs are involved as part of a systemic disease, the symmetrical distribution of lesions, a vascular or perivascular pattern of abnormal markings, and a tendency toward pleural involvement are characteristic. At least 50 abnormal states may lead to miliary or nodular foci. The author of this book performs a real service by calling attention to frequently unappreciated facts.

Bellevue Is My Home. By Salvatore R. Cutolo, M.D., with Arthur and Barbara Gelb. Cloth. $4. Pp. 317. Doubleday & Company, Inc., Garden City, New York; 575 Madison Ave., New York 22, 1956.

During the more than 200 years that Bellevue Hospital has been caring for the sick, it has grown to be an enormous institution. Some think of Bellevue as a miniature city; others say it has been the cradle of medicine in America. It is the only hospital to which four medical schools are attached: Columbia University College of Physicians and Surgeons, Cornell University Medical College, New York University College of Medicine, and New York University Post-Graduate Medical School. Faculty members from these schools exclusively staff this hospital today. The author has been closely associated with Bellevue in various capacities for more than 25 years. He states, "It costs us $17,000,000 to operate Bellevue each year, of which $14,000,000 goes for payroll, $1,360,000 for food, and $1,155,000 for medical, laboratory, and surgical supplies." The author leaves the distinct impression that the 1,000 visiting physicians, 459 interns and residents, 582 graduate nurses, 500 student nurses, and the hundreds of other attendants all embrace the ideal of kind, courteous, and efficient care for all their patients. Many interesting tales of patients and some almost miraculous cures are related. The author of such beloved songs as "My Old Kentucky Home" and "Old Black Joe" was brought to Bellevue in 1864 as an alcohol-ravaged, pitiful, and wasted figure after he had fallen across the washbowl in his room, severely cutting his neck and face. Three days later he died in the ward at Bellevue. This patient was Stephen Foster, and the old ledger showing his admission to the hospital is still there. The American Society of Composers, Authors and Publishers presented a plaque to the hospital four years ago to commemorate Foster's death. A businessman from Memphis, Tenn., now dead, for 20 years annually came to New York and stood outside the entrance to the hospital for a few moments on Jan. 13, the anniversary of Foster's death. Many stories of patients and of some famous physicians who have served the hospital, as well as some medical discoveries that were made within its walls, are recalled. A chapter entitled The Third Phase of Medicine concerns the rehabilitation services. Some chapters pertain to the great work now done by the psychiatric service. The first five chapters of the book are autobiographical.

J. A. M. A. Queries and Minor Notes. Cloth. $5.50. Pp. 334. Published for American Medical Association by C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1956.

In the past the American Medical Association has published three compilations of items from the Queries and Minor Notes department of The Journal under the title "Selected Questions and Answers." The last of these, published in 1950, covered the period 1943 to 1949. Because of the large demands for volume 3 long after it was out of print and because of requests for a new compilation, the present volume, selected from items published during the 12 months ending June, 1955, has been made available. Selection was based largely on the teaching value, general interest, and timeliness of the items, avoiding unnecessary duplication and matters so highly technical as to be of limited interest. Like the preceding volumes, this one has no index, but the table of contents is arranged for easy reference.

School Health Practice. By C. L. Anderson, B.S., M.S., Dr.P.H., Professor of Hygiene and Health Education, Oregon State College, Corvallis. Cloth. $4.75. Pp. 560, with 29 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1956.

This book was written to provide the what, how, and why of the functional school health program. It is intended to serve as a textbook for student teachers and as a reference for teachers in practice. Its principal sections include a description of the school-age child, including his appearance in health and illness and his physical and emotional development; a discussion of the organization of the school health program; and detailed descriptions of the three major aspects of a school health program—health services, health instruction, and healthful school living. This book is well organized and has an index and an appendix that contain such useful information as resources for health instruction, record and report forms, and means for evaluating a school health program. Unfortunately, the book was prepared without medical or dental consultation. In many places medical terminology is used inaccurately. The suggested relation between educators and physicians does not conform to the interprofessional consensus expressed by the National Conferences on Physicians and Schools sponsored by the American Medical Association. In the section concerned with communicable disease control, the drugs suggested for the treatment of various skin infections and infestations are recommended in a manner that implies their use in the school without local medical supervision. There is only casual mention of the need for interprofessional planning of the school health program among educators and their colleagues in medicine, dentistry, and public health. Thus, student teachers using this as a textbook will get the impression that the school health program is conceived and executed by educators who are privileged to command the services of the other professions in the community if and when they need them. The value of the book would have been materially enhanced if certain statements in the field of health, medical care, and dentistry had been checked for accuracy through professional consultation and if the spirit of interprofessional cooperation in both the planning and the carrying out of school health activities, particularly school health service, had been more clearly delineated.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

J. A. M. A. Clinical Abstracts of Diagnosis and Treatment. [Selected by Noah D. Fabricant, M.D., Editorial Associate, Journal of the American Medical Association.] Published with approval of Board of Trustees, American Medical Association. Cloth. $5.50. Pp. 661. Intercontinental Medical Book Corporation, with Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1956.

This compilation of the best of the abstracts culled from the Medical Literature Abstracts section of THE JOURNAL is chiefly concerned with the literature of 1955. The abstracts are not arranged by medical specialties, as they are in THE JOURNAL, but by organ systems, with additional chapters entitled Metabolism, Poisonings, Infections, Therapeutics, and Diagnostic Technics. The value of abstracts in general has long been recognized, and this conveniently arranged volume should be a welcome addition to the library of the busy practitioner. The book has an index.

Medicinal Chemistry. Volume II. Editors F. F. Blicke and C. M. Suter. Series of reviews prepared under auspices of Division of Medicinal Chemistry of American Chemical Society. By A. Stoll and others. Cloth. $10. Pp. 311, with illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16, Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W.C.2, England, 1956.

The second volume of this series is similar in purpose and make-up to the first, which appeared in 1951. The purpose is to provide a comprehensive summary of data on compounds having biological properties and thus to aid in the correlation of structure with activity. Each chapter, written by an authority, includes compounds having specific biological activity. Where it is not feasible, because a category may be too large to include all the information in a single chapter, a subdivision is made on a chemical basis. The present volume contains four chapters dealing with cardiac glycosides, synthetic estrogens, arylpiperidine analgesics, and β-haloethylamine adrenergic blocking agents. Most of the chapters contain a large portion of the material in table form in order to conveniently correlate activity and structure. Each chapter contains numerous references to the original literature.

Diseases of the Skin. By Richard L. Sutton, Jr., A.M., M.D., F.R.S., Chairman of Department of Dermatology, University of Kansas Medical Center, Kansas City, Kan. Eleventh edition. Cloth. $29.50. Pp. 1479, with 1972 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1956.

Successive editions of this monumental work have become a standard component of the dermatologist's library. Since the last edition, the co-authorship of Sutton and Sutton has been dissolved by the death of the senior author; but the excellence of the present edition assures the book a continued prominent place in the dermatological literature. This volume is a combination textbook, encyclopedia, and atlas. The organization is that of the traditional textbook, but each section is supplemented with brief reviews of the literature and of pertinent experimental work, descriptions of unusual cases, and extensive bibliographic references with commentary. In addition, each section is profusely illustrated with black-and-white clinical photographs and photomicrographs of outstanding quality and variety. This is an extremely valuable feature of the book. The scope of the work is comprehensive. All known skin diseases, including the exanthems, are discussed and adequately indexed. Diseases are grouped by cause when this is known, and by morphology when it is not. The table of contents clearly indicates the major classifications, but the formidable lists of diseases presented under the last three chapter headings need further subgrouping to facilitate reference. In the text, descriptions of the individual diseases are lucid and complete. The outlines of therapy are practical, explicit, and comprehensive. In some cases the author reviews the literature of therapy without comment; in others, he clearly states his preference. The inexperienced may wish for more critical evaluation, but the more experienced reader will appreciate the wide basis on which to make his own evaluation. The histopathological descriptions throughout the text are occasionally less detailed than the graduate student may wish, but for the most part they give an adequate picture.

In the 13 years since the last revision, there have been many advances in dermatology. These are well reflected in this new edition. Much new information has been included, and the sections on therapy have been thoroughly revised and brought up-to-date. The book is readable and useful. The novice may wish for more synthesis and less reference in some sections, but those conversant with the field should welcome the ready access to the source of each observation and opinion expressed. The inclusion of complete bibliographic references in parentheses within the sentences of the text is distracting but perhaps more useful than the bibliographies in small print at the end of each chapter that are found in previous editions. The book should be most useful to dermatologists and graduate students. It should also be helpful to practitioners and students with some orientation in the field. It is somewhat too large (and expensive) for a beginning textbook in dermatology.

Poliomyelitis: Papers and Discussions Presented at the Third International Poliomyelitis Conference. Compiled and edited for International Poliomyelitis Congress Cloth $7 50 Pp 567, with 442 illustrations J B Lippincott Company, 227-231 S Sixth St, Philadelphia 5; 2083 Guy St, Montreal, Canada, 1955.

As stated in the preface of this book, the demand for the published proceedings of the first two conferences was such as to leave no question whether to publish the proceedings of the third conference. The book covers the social aspects of poliomyelitis, medical care of acute cases, infection and immunity, tissue culture of the causative virus, orthopedic aspects of the disease, and physical medicine and rehabilitation. There is also a section on current trends and future prospects, as well as one in which 20 scientific exhibits are presented. The papers, which are by outstanding authorities from all over the world, are attractively printed. Extensive use is made of illustrations, most of which are clear and add to an understanding of the text. There is an index. Current interest in poliomyelitis is far greater than its importance as a public health problem would warrant, and it is to be hoped that modern methods of immunization will make it so rare that some of the attention now devoted to this disease can be directed elsewhere.

Virus Diseases and the Cardiovascular System: A Survey. By Ernest Lyon, M.D. Cloth. $5.75. Pp. 215. Grune & Stratton, Inc., 381 Fourth Ave, New York 16; 99 Great Russell St., London, W.C.1, England, 1956.

In the past few years the effects of the many virus diseases on the cardiovascular system have been recognized. Reports of electrocardiographic changes in a number of virus infections, the increasing incidence of nonspecific pericarditis and myocarditis probably of viral origin, and the relationship of rubella (German measles) in the pregnant mother to congenital heart disease in the child have made the internist and cardiologist aware of the cardiovascular problem in virus diseases. Although much has been written on the subject, pertinent information is difficult to obtain because reports are scattered through many different journals. Dr. Lyon, a well-trained microbiologist and clinician, has done a great service in reviewing a large number of articles in order to include in this volume all the pertinent information on the effect of virus diseases on the heart and blood vessels. In the first part he reviews the present concepts as to how the viruses act on the circulation; in the second part the individual diseases and their specific peculiarities are described; and in the third part rickettsial infections are discussed. An extensive bibliography is given at the end of each chapter. This book should be most welcome as a reference book to the internist and cardiologist.

Diseases of the Chest. By H. Corwin Hinshaw, M D., Ph D, Clinical Professor of Medicine, Stanford University School of Medicine, and L Henry Garland, M.B., B.Ch., Clinical Professor of Radiology, Stanford University School of Medicine, San Francisco. Cloth. $15. Pp 727, with 634 illustrations. W. B Saunders Company, 218 W. Washington Sq, Philadelphia 5; W. B. Saunders Company, Ltd, 7 Grape St, Shaftesbury Ave., London, W C.2, England, 1956.

This is an excellent presentation of diseases of the lungs by two well-qualified men, who were assisted by a few co-authors for some special subjects. The book covers all the usual and unusual diseases of the lungs, bronchi, and pleura. It is beautifully printed, and the illustrations are unusually clear. The bibliography is brief but well chosen. This volume should be of great value to students and practitioners who are interested in diseases of the chest. Its contents are so up-to-date that it should be useful for many years to come.

QUERIES AND MINOR NOTES

TYPHOID IMMUNIZATION

To the Editor:—*In her senior year, a student nurse developed typhoid. This was established by repeated positive blood cultures. She had previously received the conventional three injections of typhoid vaccine in her freshman year and was given one additional injection of vaccine in each of the succeeding years. In the future would it be logical to give typhoid vaccine to her? Does typhoid produce a subsequent immunity in a high percentage of cases? By analyzing the agglutinin response, would it be possible to come to any conclusion regarding future immunity in an individual case?*

M.D., Illinois.

Answer.—It is likely that the patient in question possesses a fairly high level of resistance to typhoid. On the other hand, there is no way to prove this with certainty in a given individual, since serologic tests do not always correlate with actual resistance to the disease. Furthermore, all immunity is relative. Immunity to typhoid is no exception, and the evidence for lasting immunity after an attack of typhoid is not as solid as is the case with certain of the infectious diseases, e. g., measles or mumps. However, in areas where typhoid is highly prevalent, it is usually a children's disease and is much less common in adults, which suggests that infection generally produces immunity. For this and other reasons it may be assumed that the patient has a fairly high resistance to typhoid and therefore she need not receive typhoid vaccine routinely. On the other hand, if she is likely to be heavily exposed to typhoid infection, it would be a reasonable precaution to administer 0.05 to 0.1 ml. of typhoid vaccine intradermally (but not on the forearm, which is hypersensitive to such injections) not oftener than every three years.

EAR INFECTION AND SWIMMING

To the Editor:—*I am a member of a fishing club that owns a 14-acre spring-fed lake. A committee has decided that, to (1) increase the food supply for the fish and (2) reduce the amount of marine weeds, the lake should be treated with fertilizer. They propose to use a commercial fertilizer known as "10-10-10," which, I understand, is composed of 10 parts each of nitrogen, phosphate, and potash. Do you think it is possible that this treatment of the water may cause swimmers to have ear infections?*

J. T. Brennan, M.D., Clarksburg, W. Va.

Answer.—Ear infection from swimming is nearly always in the form of an external otitis, the result of moisture remaining in the depth of the ear canal causing maceration of the epithelium, offering a favorable culture medium for Micrococcus (Staphlococcus) pyogenes var. aureus, Pseudomonas aeruginosa, and, occasionally, Aspergillus mold. The fertility of pond water should in no way alter its bacterial content for swimmers. It has been found that a silicone preparation, which protects the skin of the ear canal from maceration by water, is useful for swimmers who are troubled with external otitis.

FIBERGLAS

To the Editor:—*I would like to learn of the toxic effects, if any, associated with Fiberglas cloth and of the resins and catalyst used to fix and harden the resins, as used in covering boats and in general hobby materials.*

Earl Parsons, M.D., Little Rock, Ark.

Answer.—Fiberglas itself essentially is harmless. Dust from it will not provoke pulmonary fibrosis. Little such dust reaches the lungs, due to peculiar electrostatic properties of the material. Spicules of Fiberglas may penetrate the skin and lead to mechanical irritation often termed "Fiberglas warts." To facilitate weaving and other fabrications, the glass fibers sometimes are lubricated with such agents as Spindle Oil, which, in turn, possesses no significantly harmful properties. The troublesome exposure connected with the shaping of objects such as boats from Fiberglas derives from the synthetic resins employed. Notable in the group are the epoxy resins, which act both as primary skin irritants and allergens. The manufacture and use of epoxy resins involve a complex array of catalysts, plasticizers, activators, and solvents. The number may include ethylenediamine, diethylenetriamine, acetone, ethyl acetate, benzoyl peroxide, tricresyl phosphate, dimethyl phthalate, cyclohexanone, cobalt, naphthenates, allyl glycidyl ether, and others. More than one of these agents, such as tricresyl phosphate, is known to be toxic, but in resin application (not manufacture) practical exposure is unlikely. The amines constitute the chief concern. The entry of the amine radical frequently provides opportunity for the dermatitis and asthma that occur frequently after sensitization, or primary eye irritation from vapors, together with caustic contact damage on any tissue surface. It is possible that the epoxy resins per se, which are epichlorohydrin bis-phenol condensation resins, are relatively nonactive, all damage being attributable to the ancillary chemicals present.

TRANSFUSIONS IN RHEUMATIC DISEASES

To the Editor:—*I am inquiring about the use of blood transfusions in chronic, subacute polyarticular arthritis. I have inquired at our local hospital staff meetings and no one knows anything about it.*

G. E. Ramseyer, M.D., Plainwell, Mich.

Answer.—The transfusion of blood to patients with rheumatic diseases, particularly rheumatoid arthritis, was used more extensively in the past than is currently the case. Various rationales have been proposed. It has been thought that the administration of blood may have a beneficial, nonspecific, or "tonic," effect and in some manner stimulate the formation of antibodies. The transfusion of blood also has been advocated to increase the content of protein in the serum, in addition to supplying red corpuscles and hemoglobin to the rheumatoid patient in whom active stages of the disease may result in hypoproteinemia as well as anemia. The transfusion of blood usually has been favored more for patients who have the acute or subacute and febrile phases of a rheumatoid process. However, recent studies of the anemia of patients with rheumatoid arthritis generally have indicated that, as the active inflammatory process subsides, the values for hemoglobin and erythrocytes increase without specific antianemia treatment, provided the dietary intake of iron and other substances is adequate.

Normal whole blood has been most often used, but variable amounts and intervals have been advocated by different observers. Other techniques proposed have included the use of blood previously subjected to ultraviolet irradiation or blood (or plasma) obtained from pregnant women. The value claimed for these procedures has not been substantiated by the controlled, careful observations of most rheumatologists. In the course of an extensive trial of blood transfused in various manners, it was found that the benefit, if any, has been temporary and usually insufficient to justify the risks and expense involved. The transient benefit sometimes noted at times may be attributed to a mild, febrile reaction that follows the transfusion of blood. At best it would seem that the administration of blood should be considered only as part of a broad general treatment program based on the indications of each patient's condition. The indications for transfused blood should not depend merely on the ability of the patient to afford the procedure or on the availability of suitable donors. Other more effective treatment generally is equally available or more so, and it may be more practical.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

TREATMENT OF TORULAR MENINGITIS

To the Editor:—*What is the latest treatment of and prognosis in torular meningitis? What is the route of invasion into the meninges?*

William T. Cassano, M.D., Brooklyn, N. Y.

Answer.—Torular meningitis, also known as cryptococcosis or European blastomycosis, is a subacute or chronic infection caused by Cryptococcus neoformans (Torula histolytica), a yeast-like fungus. The disease may possibly be derived from an endogenous source. The route of invasion into the meninges is not generally known but is probably from the respiratory tract, which is thought to be the portal of entry. A history of a mild but definite respiratory infection can usually be obtained from patients suffering from torular meningitis. Most of the cases reported have been of the cerebral and meningeal type. The prognosis is usually poor once meningitis is established, because the host is apparently unable to develop any specific immunologic resistance. Carton and Mount (*J. Neurosurg.* 8:143,1951), in a review of 178 cases with central nervous system involvement, found only one case, that of cryptococcic meningitis treated with sulfadiazine, in which the patient could be considered as cured. Eighty-six per cent of the patients died within one year and 70% of these within three months of onset. The central nervous system disease is considered a virulent one. Although several patients were reported alive after two and a half, seven, and nine years, these still showed evidence of the disease, revealing a more indolent, milder, but rarer type of infection.

Acti-Dione, an antibiotic produced by many cultures of Streptomyces griseus, is the latest treatment. Acti-Dione itself has been unsatisfactory in central nervous system cryptococcosis. Only one of four patients with that disease treated with it and followed for one and one-half years was apparently cured with no sign of recurrence. (Carton and Liebig: *A.M.A. Arch. Int. Med.* 91:773 [June] 1953.) These authors, however, in sensitivity studies found that combinations of Acti-Dione with polymyxin B, or with compound 77, were the most potent and acted synergistically. These combinations, for want of a better remedy, perhaps with fever therapy, should be tried first. The result of the treatment may depend on the dose and route of administration. In evaluating the response to therapy, however, it must be taken into consideration that occasionally a patient with central nervous system cryptococcosis may have a spontaneous remission. Whitehill and Rawson (*Virginia M. Month.* 81: 591, 1854) reported a case of a 16-year-old girl with generalized cryptococcosis in which the lymph nodes, kidneys, liver, and spleen were predominantly involved, presenting a clinical picture resembling Hodgkin's disease. She was treated with 4.05 gm. of 2-hydroxystilbamidine given over a 19-day period with apparent cure.

HORMONES AND THE INCREASED GROWTH OF CHICKENS

To the Editor:—*Are hormones rendered inactive and destroyed by heat as in cooking? I have in mind estrogenic hormones as given to chickens and turkeys to increase their growth. I believe Canada prohibits administration of hormones to chickens. Do you know of any other countries that forbid this practice?*

M.D., New Jersey.

Answer.—Three estrogens are being used in the United States to stimulate growth rate in cattle or to increase fat deposition and improve carcass quality in chickens and turkeys. Diethylstilbestrol is administered to cattle either orally or subcutaneously in compressed pellet form. Poultry are usually implanted with diethylstilbestrol in pellet or paste form or are fed dienestrol diacetate in the ration. Cattle respond to orally given hexestrol, or dienestrol, in much the same way as to diethylstilbestrol (*J. Animal Sc.* 14:329, 1955). Assays of edible tissues of estrogen-treated cattle, chickens, and turkeys indicate that, when recommended amounts of estrogens are fed or implanted, the estrogenic activity of the meat or other organs is extremely low or in many cases undetectable. The safe use of estrogens in meat animal production depends on the lack of concentration of these substances in the tissues rather than the destruction of the compounds in the cooking process. The estrogens used are relatively heat stable. Tests with diethylstilbestrol, which has a melting point of about 170 C, show that, in meat to which diethylstilbestrol was added before cooking, the estrogens had approximately the same activity after the meat was cooked to the well-done state (*J. Animal Sc.* 13:138, 1950). In Canada diethylstilbestrol may be fed to cattle at a level not to exceed 10 mg. per day (similar to the U. S.). At present no methods of administering estrogens to poultry have been approved by Canadian food and drug officials.

GLYCOSURIA IN ELDERLY PATIENTS

To the Editor:—*Several male diabetics between 62 and 72 years of age not on insulin therapy and free from urinary sugar for many years have begun to show 0.25 to 0.5% sugar in spite of strict dietary care. In all cases this follows diminished activity due to retirement or to physical causes. Increased activity would not be advisable in most of these men who are suffering from the concomitants of diabetes or other chronic disease. Would administration of small doses of any of the long-lasting insulins be advisable?*

M. D., New York

Answer.—The presence of consistent glycosuria, although of mild degree, in elderly patients calls for the administration of small doses of one of the long-lasting insulins. Since these patients generally have an elevated renal threshold for glucose, the presence of sugar in the urine means that the blood sugar level is considerably above normal. Hypoglycemia is of course to be avoided, but patients in the older age groups are, as a rule, relatively insensitive to the action of insulin so that this danger is not great. It is suggested that 10 units of isophane insulin or lente insulin be used as a beginning daily dose and that, after a few days, the blood sugar level be determined in the late afternoon, since this is the period at which these preparations are most active. Postprandial blood sugar values of approximately 150 mg. per 100 cc. would be considered safe and acceptable.

TETANUS IMMUNIZATION

To the Editor:—*Would it be advisable to substitute at the time of an injury the use of three 0.5-cc. doses of tetanus toxoid (fluid or precipitated) at two-week intervals instead of tetanus antitoxin in order to prevent serum sickness and anaphylaxis that may occur with the use of tetanus antitoxin?*

Milton Jabush, M.D., Lakewood, N. J.

Answer.—It would be inadvisable to substitute three doses of tetanus toxoid for one dose of tetanus antitoxin at the time of injury in individuals who had had no previous toxoid immunization. The injection of tetanus toxoid at two-week intervals for three doses in an unimmunized patient would produce adequate circulating antibodies against tetanus infection in about five or six weeks after the first injection This would almost certainly permit the development of some cases of active tetanus with incubation periods of 3 to 14 or more days. The best way to prevent serum sickness and anaphylaxis resulting from inoculations of tetanus antitoxin would be by universal toxoid immunization. In this manner a booster injection of toxoid at the time of injury would recall adequate concentrations of circulating antibodies into the blood stream, protect the patient from tetanus, and eliminate the danger of serum sickness or anaphylaxis from the antitoxin

REMOVAL OF STAINS ON GIRL'S BACK

To the Editor:—*A Negro girl, aged 25, has a history of acne of the face, chest, arms, and back of 10 years' duration The pustular lesions have resolved, leaving large blackish stains that have coalesced on the back. These stains now cause her mental distress. Can you suggest any method that would cause these stains to disappear?*

Reuben H. Pearlman, M.D., Pittsburgh

Answer.—The pigmentation will most likely disappear in time, but, if the young woman is impatient, she might hasten matters by applying Benoquin ointment. This should be done cautiously to avoid contact dermatitis and/or too much depigmentation.

Defense Moving Ahead on Medicare Program • •
Small Business Agency Making Facilities Loans • •
Mine Workers Medical Spending Up • •

MILITARY DEPENDENT PROGRAM

Aiming at having the operation in effect by Dec. 8 as provided in the law, the Defense Department is moving ahead with its work on the new military dependent medical care program, now identified as "medicare." Under the program, enacted at the last session of Congress, dependents are defined, and recognized dependents for the first time have statutory authority for government-paid medical care. Parents and parents-in-law, if 50% or more of their support is furnished by the serviceman, are entitled to full benefits under the program, either in military facilities or in private facilities under arrangements currently being contracted for by the Department of Defense. In private facilities, dependents are charged the first $25 of costs. The big problem facing the Defense Department now is how to make fiscal arrangements for supplying them with private benefits. The Secretary of Defense has the right to limit or deny private care to dependents in areas where military medical facilities are available and where the military mission will not be impaired.

Under present plans, state medical societies are the key unit in arranging private medical (as distinguished from hospital) care for service families. The Defense Department contemplates calling representatives of state societies to Washington in the near future to work out with them individual contracts for each state. The plan is to have the state society select its own agents (the society itself, Blue Shield, commercial companies, or possibly banks) and set a fee schedule acceptable to the Defense Department.

In preparation for meetings with state society representatives, the Defense Department task force handling preparations for the program expects to work out a model state contract, in consultation with state society advisers. As a preliminary step, several state societies drew up the type of contracts they consider workable in their areas for the guidance of the department.

To put the hospital care phase into effect, the department has tentatively decided to allocate coverage on the basis of Army areas (the Army is the medicare agent for all three services), with Blue Cross responsible for a majority of the areas and commercial insurance companies for the remainder. Before this decision was made, the department held a number of conferences with representatives of the professional and insurance organizations involved.

One of the first major steps in preparation for medicare was issuance of a directive by the Secretary of Defense. It embodies the department's concept of the law and general instructions to the uniformed services as to implementation of the law. The directive is a detailed document of about 36 pages, in contrast to the relatively brief text of the law. The directive indicates what kind of care is to be provided in military and civilian facilities, and under what circumstances; how dependents will be identified; and what types of outpatient care are to be provided in military and civilian facilities. (In the latter, outpatient care is limited in general to such emergencies as injuries, lacerations, or poisonings.) Prior to the series of Defense Department meetings with state society representatives to work out contracts, regulations will have to be issued jointly by the Defense Department and the Department of Health, Education, and Welfare. Agreements with state societies will be based on these regulations.

BUSINESS AGENCY LOANS TO PRIVATE HOSPITALS

Another agency of the federal government has moved for the first time into the health field. The Small Business Administration, an independent agency reporting to the President, announces it is receiving applications for loans to privately owned hospitals, nursing homes, and laboratories. Funds may be used for expansion, improvement, and working capital. In addition to being privately owned, to be eligible the facilities must be operated for profit and have not more than 50 beds at the time of application. All laboratories are to be considered small unless operated in connection with a proprietary hospital of more than 50 beds. The Small Business Administration listed these definitions of facilities:

Hospitals are those health facilities licensed as hospitals providing inpatient medical or surgical care of the sick or injured, including obstetrics. Nursing homes are those facilities for accommodation of convalescents or other persons who are not acutely ill and not in need of hospital care but who may require nursing care and related medical services. Medical and dental laboratories are those facilities that provide services to physicians, dentists, hospitals, and similar health facilities. The loans are of two types: participation loans, which are made jointly with banks and other private lending institutions, and direct loans, where no participation is available. The agency explains further that loans may be used for building new facilities, for expansion or improvement of existing plants, or for working capital.

"The amount which the Small Business Administration may lend is limited by statute to a maximum of $250,000 to any one borrower," an agency announce-

GLYCOSURIA IN ELDERLY PATIENTS

To the Editor:—*Several male diabetics between 62 and 72 years of age not on insulin therapy and free from urinary sugar for many years have begun to show 0.25 to 0.5% sugar in spite of strict dietary care. In all cases this follows diminished activity due to retirement or to physical causes. Increased activity would not be advisable in most of these men who are suffering from the concomitants of diabetes or other chronic disease. Would administration of small doses of any of the long-lasting insulins be advisable?*

M. D., New York.

Answer.—The presence of consistent glycosuria, although of mild degree, in elderly patients calls for the administration of small doses of one of the long-lasting insulins. Since these patients generally have an elevated renal threshold for glucose, the presence of sugar in the urine means that the blood sugar level is considerably above normal. Hypoglycemia is of course to be avoided, but patients in the older age groups are, as a rule, relatively insensitive to the action of insulin so that this danger is not great. It is suggested that 10 units of isophane insulin or lente insulin be used as a beginning daily dose and that, after a few days, the blood sugar level be determined in the late afternoon, since this is the period at which these preparations are most active. Postprandial blood sugar values of approximately 150 mg. per 100 cc. would be considered safe and acceptable.

TETANUS IMMUNIZATION

To the Editor:—*Would it be advisable to substitute at the time of an injury the use of three 0.5-cc. doses of tetanus toxoid (fluid or precipitated) at two-week intervals instead of tetanus antitoxin in order to prevent serum sickness and anaphylaxis that may occur with the use of tetanus antitoxin?*

Milton Jabush, M.D., Lakewood, N. J.

Answer.—It would be inadvisable to substitute three doses of tetanus toxoid for one dose of tetanus antitoxin at the time of injury in individuals who had had no previous toxoid immunization. The injection of tetanus toxoid at two-week intervals for three doses in an unimmunized patient would produce adequate circulating antibodies against tetanus infection in about five or six weeks after the first injection. This would almost certainly permit the development of some cases of active tetanus with incubation periods of 3 to 14 or more days. The best way to prevent serum sickness and anaphylaxis resulting from inoculations of tetanus antitoxin would be by universal toxoid immunization. In this manner a booster injection of toxoid at the time of injury would recall adequate concentrations of circulating antibodies into the blood stream, protect the patient from tetanus, and eliminate the danger of serum sickness or anaphylaxis from the antitoxin.

REMOVAL OF STAINS ON GIRL'S BACK

To the Editor:—*A Negro girl, aged 25, has a history of acne of the face, chest, arms, and back of 10 years' duration. The pustular lesions have resolved, leaving large blackish stains that have coalesced on the back. These stains now cause her mental distress. Can you suggest any method that would cause these stains to disappear?*

Reuben H. Pearlman, M.D., Pittsburgh.

Answer.—The pigmentation will most likely disappear in time, but, if the young woman is impatient, she might hasten matters by applying Benoquin ointment. This should be done cautiously to avoid contact dermatitis and/or too much depigmentation.

sonnel see cases formerly considered hopeless and helpless respond to constructive assistance through full utilization of available services, and cooperate with the rehabilitation efforts of the fund's medical services. . . . As experience is gained, it is hoped that total patient care, which is rehabilitation at its best, can be achieved for every physically disabled fund beneficiary."

MISCELLANY

The Internal Revenue Service says that a grant to a taxpayer primarily to further his education and training by enabling him to complete work for his doctoral degree, "with the taxpayer under no commitment to the grantor" as to his educational objectives, may be excluded from the recipient's taxable income. . . . Systematic methods developed by the National Bureau of Standards for solving radiation penetration problems associated with medical use of radiation are discussed in the bureau's Summary Technical Report 2039, available from the bureau. . . . The Defense Department is understood to have extended the date for termination of the Army and Air Force veterinary corps to Nov. 30. Secretary Wilson originally ordered the two veterinary corps (the Navy has none) to be closed out by last July 1. However, the corps are established by law, and Congress will probably look into the matter after the session opens in January. Abolition of the corps has been opposed by the American Medical Association and other professional groups. . . . Under a grant from the Joint Commission on Mental Illness and Health, the University of Michigan Survey Research Center will conduct a national opinion survey as a part of the commission's three-year sampling of 2,500 individuals on their attitude toward the knowledge of mental illness and emotional strength or well-being. . . . The Navy, celebrating the 114th anniversary of the founding of its Bureau of Medicine and Surgery, points out that it now has on duty 550 physicians certified by American boards and that 337 of its doctors are in residency training. . . . The U. S. Public Health Service has awarded a special citation to the Union Pacific Railroad in recognition of the fact that all the road's operating dining cars had a rating of 95% or better on PHS inspections during a full year. The last similar award went to the Erie Railroad in 1953. . . . An October draft call for 300 physicians to be assigned to the Navy has been announced by the Defense Department, the first call since last May. These physicians report for duty later in the year. . . . The Public Health Service has announced that examinations for appointment of medical officers in the commissioned corps of the PHS will be held in November. Entrance pay for the two grades, assistant and senior assistant surgeon, is $7,498 a year. The PHS explained that assistant grade entrants are assigned the temporary grade of senior assistant. This, said PHS, is in accord with recent policies providing certain career incentives to medical and dental officers of the uniformed services. The rank of assistant surgeon requires 7 years of collegiate and professional training, and the rank of senior assistant surgeon, 10 years.

THE FACIAL NERVE IN PAROTID SURGERY

Oliver H. Beahrs, M.D.
and
Bernard F. L'Esperance, M.D., Rochester, Minn.

• *The excision of small parts of the parotid gland is liable to result in damage to the facial nerve, which runs through the substance of the gland. Such damage is hard to avoid if the nerve is not well exposed, and the surgeon has to choose between the danger of facial paralysis and the danger of incomplete performance of the intended extirpation. A good exposure makes it possible to choose between removal of the superficial portion of the gland and total removal of both superficial and deep portions by careful dissection. If there is a malignant tumor in the gland, excision must be total and the nerve must be sacrificed. Nerve grafting, using a section from the greater auricular nerve, was successful in preventing permanent facial paralysis in a case of this kind here described.*

Surgical treatment of the parotid gland in the past has been manifestly influenced by the intimate relationship between the parotid gland and the facial nerve. The dread of damaging this nerve has been paramount in the minds of surgeons dealing with lesions in this region. Paralysis of the nerve produces disfigurement, with psychic trauma that many persons are unable to endure; in not a few instances, suicide has appeared to be the only escape. Consequently, it is with adequate reason that the surgeon has gone out of his way to preserve this nerve, in many instances to the point of jeopardizing what he is attempting to accomplish.

General Background

The seventh cranial nerve, after emerging from the cranium through the stylomastoid foramen, passes anteriorly, laterally, and slightly inferiorly for approximately 1 cm. and then enters the posterior border of the parotid gland. In the substance of the gland, it divides into two main trunks, namely, the superior temporofacial and the inferior cervicofacial. These, in turn, divide into five terminal branches, the temporal, zygomatic, buccal, mandibular, and cervical, which emerge at the anterior border of the parotid. A predominant concept has originated from the work of McWhorter[1] that the gland is composed of two distinct lobes, one superficial and the other deep, the two being connected by an isthmus. The facial nerve supposedly divides into its two main branches at the posterior border of the isthmus, one branch passing superiorly, the other inferiorly. From our experience, we have not been able to demonstrate this arrangement and so have preferred to consider portions of the gland as lying either superficial or deep to the nerve, which courses directly through the substance of the parotid gland. This opinion has been expressed by Martin[2] and Lathrop[3] and, more recently, by Tabah.[4]

As already indicated, it is largely because of fear of inflicting damage to the facial nerve that efforts to remove tumors of the parotid gland have been ineffectively conservative. The high incidence of recurrence in practically all series reported bears out this statement. Martin[2] noted that 36% of all patients with parotid tumors coming to the New York Memorial Hospital on first admission had had one or more episodes of recurrence after one or more previous operations. Rawson and Horn[5] followed up patients operated on for mixed tumors of the parotid gland for a period of at least 10 years and found a recurrence rate of 31%. Kirklin and associates,[6] in reviewing the experience at the Mayo Clinic, found that 34% of patients with mixed tumors had been previously treated when first seen at the clinic. Figures such as these probably are directly attributable to inadequate operation resulting from lack of knowledge of the nature of parotid tumors, fear of injuring the facial nerve, and inexperience in a proper surgical approach.

Various methods have been described for identifying the facial nerve. Sistrunk,[7] and Adson and Ott,[8] advocated identifying the marginal mandibular branch of the facial nerve and tracing it posteriorly to locate the main stem of the nerve. McCormack and coworkers[9] advised commencing the procedure at the anterior border of the gland, locating the terminal branches in this region, and then tracing the branches

---

From the Section of Surgery, Mayo Clinic and Mayo Foundation (Dr. Beahrs) and Fellow in Surgery, Mayo Foundation (Dr. L'Esperance). The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

posteriorly until the main trunk is reached. Brown's group[10] favored a direct approach after adequate exposure was obtained by wide reflection of the cutaneous flaps. Byars[11] identified the posterior facial vein as the primary step, using this landmark to isolate the cervicofacial division of the nerve. The approach that has most adherents probably is the afore-mentioned method of McCormack and associates. We consider that this technique makes for a difficult and time-consuming operation with a greater probability of damaging the nerve or portions of it. Locating the marginal mandibular branch and tracing this to the main trunk are not advised for the reasons just given; also, much time can be lost in attempting to locate and isolate this branch. We think that attempting to approach these tumors directly by local excision or enucleation is contraindicated; by such an approach, one never can be sure of completely circumventing the lesion, and the danger of neural damage is increased because of the lack of exposure of the nerve. It is this method of attempting to excise locally a growth of the parotid gland that has especially resulted in high rates of recurrence. Locating the posterior facial vein to find the cervicofacial division of the nerve can be fraught with difficulty because of the varied arrangements of veins in this region and the variable relation between vein and nerve, thus increasing the danger of traumatizing the nerve.

We endorse the method advocated by Janes,[12] whereby one first identifies the stem of the facial nerve after it leaves the stylomastoid foramen and then traces the branches peripherally under direct vision. The main trunk of the nerve in an adult is always consistent in its location and is of sufficient size so that with reasonable care it should not be injured. The nerve in the adult is found directly anterior and deep to the mastoid process.

Operative Technique

Parotidectomy.—General anesthesia is administered through an endotracheal tube. The field is widely draped to include the ear, corner of the eye, and corner of the mouth on the homolateral side, so that motion of the face can be seen by the surgical team. The familiar Y or inverted T incision is made, with one limb extending from behind the ear below and parallel to the inferior margin of the mandible for 6 to 7 cm. The other limb passes upward and anterior to the ear in one of the natural creases of the skin. The cutaneous flaps are widely developed, and the dissection is then commenced at the posteroinferior border of the gland. With traction exerted superiorly and anteriorly, the posterior border of the gland is freed from the sternocleidomastoid muscle and, in a deeper plane, from the posterior belly of the digastric muscle. Dissection then passes downward along and anterior to the cartilaginous external auditory canal and the mastoid process. As the dissection is carried medially and deep to the body of the mastoid process, the main trunk of the nerve invariably is found. If upward traction is applied to the gland, the nerve can be palpated in the substance of the gland before it can be seen. With the main trunk of the nerve exposed, there is little occasion to stimulate or otherwise traumatize it.

After the stem of the nerve has been located, the superficial portion of the gland is separated from its branches by blunt dissection, using the closed tip of a small, pointed dissecting scissors. The nerve is always under direct vision, and, as long as the dissection remains superficial to the nerve, there is no danger of damaging it. Hemostasis is maintained first by tension, traction, and countertraction on the tissues and, subsequently, after the dissection is complete, by application of mosquito hemostats and ligatures. Traction exerted by means of Kocher's forceps placed on the superficial part of the gland with proper tension and in the right direction greatly facilitates the operation and cannot be overstressed. It is amazing with what dispatch superficial parotidectomy can be accomplished by a team familiar with the technique.

If the tumor is situated in the deeper tissues of the gland, total parotidectomy is indicated. After completion of the superficial dissection, the external carotid artery and posterior facial vein are divided at the inferior border of the deep portion of the gland, the superficial temporal artery and vein are divided at the superior border, and the internal maxillary artery is severed at the anterior border. After the facial nerve and its branches are gently retracted out of the way with nerve hooks, the deep portion of the gland is removed either between the two main branches of the nerve or below its inferior branch, whichever is more expedient.

We treat benign tumors of the superficial portion of the gland by superficial parotidectomy. As already indicated, if the tumor is situated deep to the nerve, total parotidectomy with preservation of the nerve is performed. If the character of the tumor is questionable, a biopsy is done, and fresh frozen sections of tissue are studied immediately. If malignant changes are thus found, the surgical procedure necessarily has to be extended. Carcinoma of the parotid gland poses a different problem, in that total parotidectomy invari-

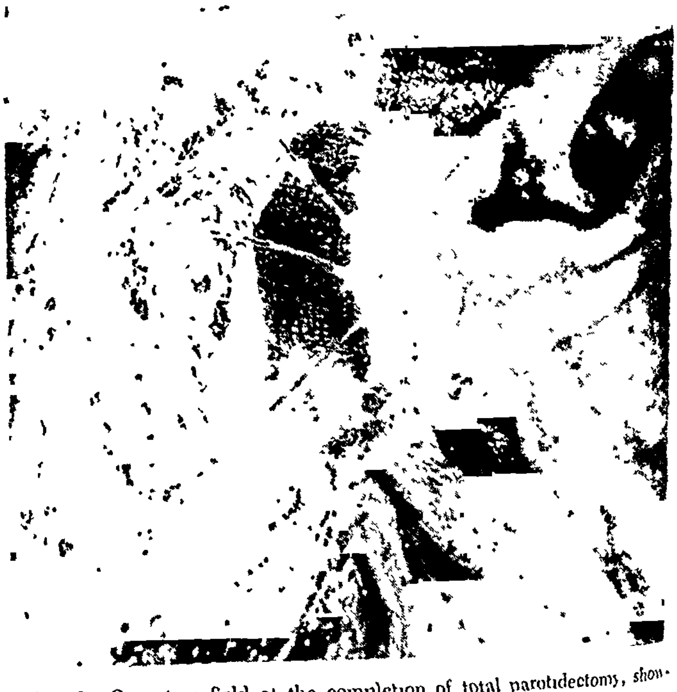

Fig. 1.—Operative field at the completion of total parotidectomy, showing nerve graft in place.

ably should be performed. The nerve in most instances must be sacrificed in order to accomplish adequate excision of the tumor. However, the nerve or a portion of it might be preserved in selected instances in which the nerve is free of the tumor or in which the tumor is of a low grade of malignancy or is well encapsulated. When the nerve is sacrificed, the patient is left with facial paralysis.

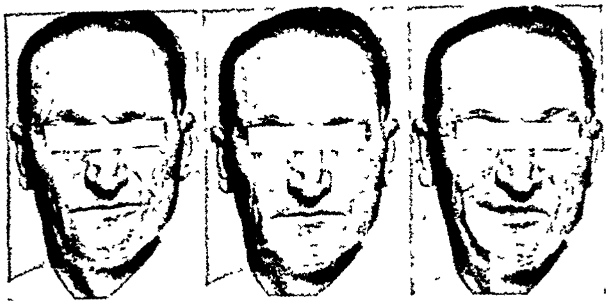

Fig. 2.—Appearance of patient 16 months after operation, demonstrating return of gross facial function.

Repair for Facial-Nerve Palsy.—Techniques proposed to improve the results of palsy of the facial nerve include (1) nerve anastomosis or nerve grafts, (2) repair by muscle operation, (3) repair by use of supporting fascial strips, and (4) a combination of the last two. If the nerve has been sacrificed in the course of the primary surgical procedure, it appears reasonable to state that reestablishment of continuity of the nerve by suture or nerve graft should be the procedure of choice, if it is possible to accomplish it. Only this reconstructive procedure will be considered in this paper.

Bunnell[13] claimed the first successful intratemporal repair of the facial nerve by nerve graft, using the sural nerve for donor purposes. Maxwell[14] added much stimulus to the problem in 1951 when he reported four cases, in three of which he used grafts from the greater auricular nerve to bridge various defects in the facial nerve. More recently, Conley[15] presented a technique that he had used on seven occasions in dealing with malignant tumors of the parotid gland. This consists of bridging the defect with a nerve graft procured from the contralateral side of the neck and composed of the greater auricular nerve and cutaneous filaments. Anastomoses are protected by using small, windowed plastic-tube cylinders. His entire procedure includes total radical parotidectomy and radical dissection of the neck. Auxiliary suspensions with fascia lata were carried out in one instance, and rotation of the masseter muscle was done in three instances along with nerve grafting. In recent years, we have inserted nerve grafts in selected cases and would like to record one instance in which the patient has been followed sufficiently long to illustrate the result.

Report of a Case

A 50-year-old man first registered at the Mayo Clinic in January, 1954. A mole had been present on the left temple for more than 15 years, during which time it had grown slightly. Four months prior to admission to the clinic, he had noticed a small lump in the region of the left parotid gland that had disappeared spontaneously but had reappeared about a month before admission and had continued to grow. Two weeks before admission, the tumor in the parotid region had been removed and biopsy of the mole had been performed. The lesions were said to be malignant, and the patient was referred to the clinic for further evaluation. Examination at the clinic revealed a localized nodular plaque in the left upper preauricular region measuring 1.5 by 1.5 cm.; it was ill-defined in character and was steel blue. An incision was present over the left parotid gland. Cervical lymph nodes were not palpable. Study of the tissue that had been removed elsewhere disclosed a diagnosis of malignant melanoma of the left temporal region with metastasis to the left parotid gland.

Operation at the clinic consisted of wide excision of the melanoepithelioma, radical total parotidectomy on the left, and radical dissection of the left side of the neck in continuity. The homolateral greater auricular nerve was used to bridge the gap between the main trunk of the facial nerve and its peripheral branches, brought together into three groups; 00000 silk was used for the anastomosis (fig. 1). Plastic closure of the defect in the left temporal region was carried out, with a skin graft applied to the defect in the left temporal region. The pathologist reported a melanoepithelioma measuring 3 by 1.5 cm. in the skin of the parotid region, with metastatic involvement of three superficial cervical lymph nodes and five nodes in the deep jugular region. The patient has been examined subsequently at the clinic in May, 1954, and June, 1955; no evidence of recurrence of the melanoepithelioma has been found. Examination of facial function in June, 1955, revealed good gross motion of all groups of muscles supplied by the facial nerve (fig. 2). A cosmetic defect was not noticeable.

Summary

Superficial parotidectomy should be the minimal surgical procedure used in the treatment of tumors of the parotid gland. The facial nerve can be easily exposed and dissected free of the gland by first exposing the main trunk deep and medial to the mastoid process. If the character of the tumor necessitates removal of the facial nerve, a nerve graft should be used at the time of the primary surgical intervention, if possible, to bridge the gap as the initial step in the treatment of the cosmetic deformity resulting from sacrifice of this nerve. If this should fail, other plastic procedures can be tried.

THE ELECTROCARDIOGRAM AS A SAFEGUARD IN PERICARDIOCENTESIS

Linton H. Bishop Jr., M.D., Emory University, Ga., E. Harvey Estes Jr., M.D.
and
Henry D. McIntosh, M.D., Durham, N. C.

• *Damage to the myocardium during pericardial paracentesis has occasionally been severe enough to result in pericardial tamponade and death. Anamil experiments here described showed that contact of the tip of the needle with the myocardium could be detected electrocardiographically if the needle was connected in such a way as to constitute an exploring electrode with the machine set as in recording chest leads. Contact with the myocardium is indicated by elevation of the S-T or the P-R segment, depending on whether the ventricle or the auricle is disturbed. This technique has been used in 40 cases of pericardial paracentesis. All were without complication, though the ventricular cavity was entered inadvertently in six instances. The danger of unintended puncture of the ventricle can be minimized by recognizing the existence of a lag between the appearance of changes in the electrocardiogram and the communication of this fact to the operator.*

In spite of the usefulness of pericardial tap in the diagnosis and therapy of pericardial diseases, the procedure is usually performed with some reluctance because of the occasional reports of pericardial tamponade and death after the procedure. The exact incidence of such complications is not known, but a recent survey revealed that the majority of a group of prominent cardiologists and surgeons had personal knowledge of one or two such accidents.[1] Since 1949, we have used the electrocardiogram as an additional safeguard during this procedure. The electrocardiogram is used as an indicator of the contact of the needle with the myocardium.

Technique

Prior to the tap, electrodes are applied to the arms and legs of the patient, to which are attached the lead wires of a direct-writing electrocardiograph. The "chest" or "precordial" lead wire from the machine is attached to the shank of the pericardial needle by means of an extra length of wire with alligator clamps at both ends (fig. 1). The machine is set to record a V lead, which means that the pericardial needle becomes the exploring electrode. The pericardial tap is carried out in the usual manner, except that as the needle is introduced the electrocardiogram is continuously monitored by an observer other than the operator.

Observations

The contact of the needle with the myocardium is signaled by the appearance of a striking elevation of the S-T segment, such as is seen in figure 2, if the ventricular muscle is contacted, or of the P-R segment if the auricle is contacted. The appearance of such a change is the signal for withdrawal of the needle.

Experimental studies on dogs have shown that actual entry of the needle into the myocardium is not necessary for the production of this current of injury. All that is required is a slight distortion of the epicardial layers, even through an intact pericardium. Figure 3 shows such a record obtained from an experimental animal. In the first section of the record, the needle is in contact with the chest wall only. In the second section the needle is in light contact with the left ventricle through an intact pericardium, with a small saline solution–soaked cotton pledget used as a means of contact. In the remaining sections firm pressure is exerted through the intact pericardium, first over the left ventricle and then over the left auricle. Note the S-T segment elevation in the former, the P-R segment elevation in the latter. It is reasoned that this feature will occasionally signal the contact of the needle with an intact pericardium immediately overlying the heart with no intervening layer of fluid, thus preventing actual entry of the needle into the pericardial sac with the accompanying risk of cardiac injury.

Figure 4, obtained from the same animal as the preceding figure, shows the further changes with actual entry of the needle into the myocardium. The changes are felt to arise in the myocardial fibers immediately surrounding the needle. These forces are not of sufficient magnitude to deform the P-R or S-T segment in more remote leads; therefore, the recording must be made from the pericardial needle itself.

In one patient the pericardial needle could not be forced through the pericardial sac because of its extreme thickness and leathery consistency. In this instance the electrocardiogram failed to show any change.

Occasionally such changes as have been previously described have been seen during the course of withdrawal of fluid, as the epicardium is pulled against the tip of the needle by the suction of the syringe. Usually the nature of this contact is evident to the operator, who can avoid such contact by a shift of needle position. We have used the technique or have directly observed its use in about 40 cases of pericardiocentesis. All were done without complication, though the ventricular cavity was inadvertently en-

tered in six instances in spite of this additional precaution In these six instances the failure of the technique to prevent entry of the needle into the cavity resulted not from lack of change in the electrocardiogram but from a delay in response on the part of the observer or the operator.

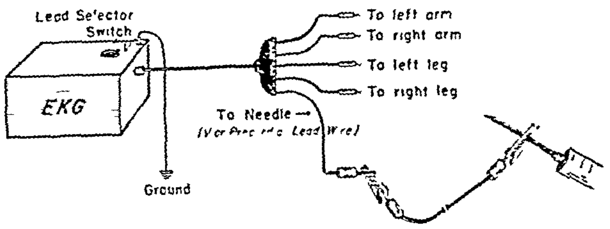

Fig 1 —Method of attaching an electrocardiograph to the pericardiocentesis needle The alligator clamp may also be attached to the handle of a Kelly clamp applied to the shank of the needle

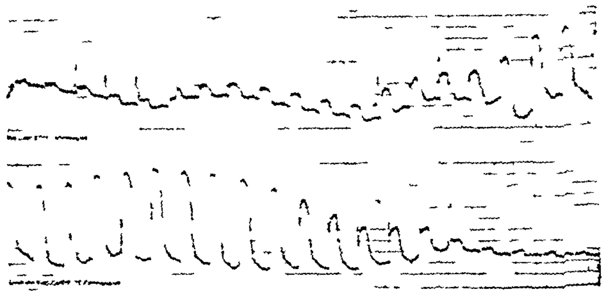

Fig 2 —Example of the striking S-T segment shift obtained on contact of the needle with the ventricular myocardium The electrocardiogram was taken during pericardiocentesis, with the needle used as an exploring electrode (Record is continuous)

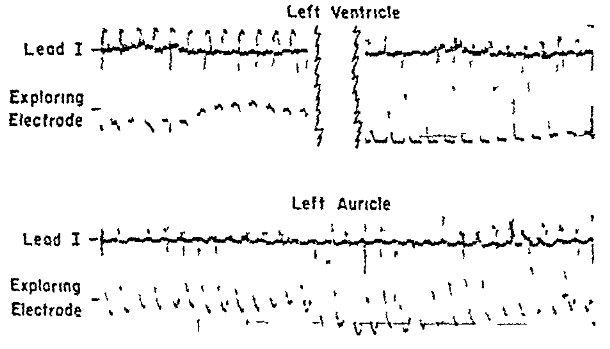

Fig 4 —Further change in S-T and P-R segments with entry of the needle into the myocardium (record from animal as figure 3).

Comment

The advantages of the use of the technique are felt to be threefold. 1. It will occasionally prevent the entry of the needle into the pericardium when no cushioning layer of fluid is present. 2 It immediately signals the entry of the needle into the myocardium, allowing the operator to withdraw promptly without unnecessary manipulation, with the accompanying risk of myocardial laceration. 3. It immediately clarifies the source of any grossly bloody fluid obtained from the pericardial needle. If bloody fluid is obtained without the appearance of S-T or P-R segment shift, such as has been described, one need have no fear that the fluid is being obtained from the chambers of the heart rather than the pericardial sac.

Since the exact incidence of serious complications following pericardiocentesis is not now known, we are not able to objectively measure the degree of protection afforded by the use of the described technique. The increased sense of security afforded by its use is unmistakable, however, and it has quickly become a routine procedure in the several hospitals in which it has been introduced. The lag between the appearance of changes in the electrocardiogram and the communication of this fact to the operator is a definite limitation, but can be minimized by experience on the part of both observer and operator.

Summary

The electrocardiogram has been used as an additional safeguard in cases of pericardiocentesis, serving as an indication of the contact of the needle with the myocardium.

Diagnosis in Brucellosis.—It is unfortunate there is no one reliable, specific test generally available for the diagnosis. In the diagnosis of brucellosis, the finding of Brucella by blood culture is diagnostic, but the test requires careful and rigid technique not available to that great group of practitioners most likely to observe the early cases. Then, too, the obtaining of a positive culture is largely a matter of accident in acute brucellosis and rarely found in chronic brucellosis. We should emphasize that negativity of any one test does not necessarily indicate that a Brucellar infection is not present, either in acute or chronic pulmonary brucellosis. A number of these diagnostic discrepancies may be mentioned. The agglutination test is of significance, only, if positive. A positive intradermal reaction indicates increased sensitivity to Brucella antigen but does not signify whether the infection is active, on the other hand, negative reactions have been observed in acute Brucella infections with positive blood cultures The opsonocytophagic test requires accurate technique with virulent Brucella organisms Increased phagocytosis with a positive intradermal reaction suggests a still active infection, although it may be logical to infer that a high degree of phagocytosis implies a balance between infection and immunity, but it does not mean that a Brucella infection is not present Conditions, such as stated, produce a situation seemingly impossible for solution, but it is my opinion a diagnosis can be made in a large percentage of the cases observed — A. PROCEDURE FOR CLINICAL EVALUATION OF RENAL FUNCTION

Lawrence G. Raisz, M.D., Jack D. Rosenbaum, M.D., Thaddeus E. Prout, M.D.
and
W. Henry Russell, M.D., Boston

• *The procedure described is particularly helpful in evaluating the renal status of patients whose plasma concentrations of nonprotein nitrogen or urea may be but slightly elevated while creatinine clearance values may have fallen as low as 50 or 25% of normal. This includes many hypertensive patients, in whom the use of hypotensive drugs or sympathectomy may be under consideration. The test involves administering a water load of 2,000 ml. within two hours. This should normally lead to a diuresis of more than 8 ml. per minute. The collection of a blood sample for determination of creatinine, the injection of phenolsulfonphthalein, and the collection of urine samples are all timed in such a way as to yield figures for both glomerular and tubular functional capacity. The mean values for endogenous creatinine clearance by this method were 120 and 100 ml. per minute respectively, in 40 healthy men and 10 healthy women. The normal phenolsulfonphthalein excretion figures ranged from 25 to 45% for the first 15 minutes and from 55 to 80% for total two-hour excretion. The test is obviously contraindicated in the presence of acute renal failure with oliguria; in less severe forms of renal impairment it is informative and avoids the hazards of concentration tests involving restriction of fluid intake.*

In the selection of laboratory procedures for the clinical evaluation of renal function it is frequently desirable to include one test that indicates the magnitude of the glomerular filtration rate and another that serves as a measure of renal tubular function. The present report describes a convenient method for combining two such tests in a single procedure; this consists of the measurement of endogenous creatinine clearance and phenolsulfonphthalein excretion during a water diuresis.

Procedure

No special preparation of the patient is required, although an extra 500 ml. of water may be given on the evening prior to the test. The protocol employed is given in table 1. The patient remains recumbent and does not smoke during the procedure. The amount of water and the time of its administration need not be exact. A sufficiently large load is given to ensure that water diuresis will be maintained at or near a peak rate during the first three urine collection periods. The urine collections and the injection of phenosulfonphthalein should be timed to the nearest minute. Except when significant impairment of bladder function is present, most patients are able to void satisfactorily at the specified time intervals. The blood sample can be obtained and phenolsulfonphthalein injected through the same needle, but care must be taken to avoid contaminating the blood sample with phenolsulfonphthalein, since this dye interferes with creatinine analysis. Accurate measurement of the amount of phenolsulfonphthalein injected is essential.

TABLE 1.—*Procedure for Evaluating Renal Function*

Elapsed Time, Hr.	Actual Time,* A. M.	Procedure
0	6:30	Drink 1,000 ml. of water within ½ hr.
½	7:00	Drink 250 ml. of water
1	7:30	Void and discard, drink 250 ml. of water†
1 ½	8:00	Void and discard, drink 250 ml. of water
2	8:30	Collect urine sample 1, drink 250 ml. of water
2 ½	9:00	Collect urine sample 2
2 ¾	9:15	Obtain blood sample for creatinine, then inject 1 ml. of phenolsulfonphthalein
3	9:30	Collect urine sample 3
3 ¾	10:15	Collect urine sample 4
4 ¾	11:15	Collect urine sample 5

* The test may, of course, be begun at any time desired.

† Voiding at this time prevents overdistention of the bladder and helps accustom the patient to the procedure.

Phenosulfonphthalein concentration in the urine is measured most accurately with a photoelectric colorimeter, but visual techniques are also satisfactory. Creatinine is determined by the Jaffe reaction,[1] which also measures a small amount of noncreatinine chromogen in the serum. Although more specific methods for the measurement of creatinine are available,[2] the simpler direct method is adequate for clinical use. The calculation of creatinine clearance is as follows:

$$\frac{\text{urine creatinine (mg./100 cc.)} \times \text{urine flow (ml./min.)}}{\text{serum creatinine (mg./100 cc.)}} = \begin{array}{c}\text{Creatinine}\\ \text{clearance}\\ \text{(ml./min.)}\end{array}$$

Results of a normal test and the method of recording are shown in table 2. If there is marked discrepancy in the urine flow or creatinine clearance values between the two clearance periods, the results are not reliable. Unless a high urine flow has been achieved prior to the first collection period, the first creatinine clearance value may be considerably higher than the second because the bladder and renal dead space contain residual urine of high creatinine concentration formed before water diuresis began. When this more concentrated urine is "washed out" and collected during the first period of high flow, an erroneously high value for urine creatinine concentration is obtained.

The procedure can be modified to measure the function of each kidney separately during cystoscopy. Large ureteral catheters (7 F. or 8 F.) are used to minimize leakage. In addition, the bladder is drained initially and washed out at the end of each collection period and the irrigation fluid is analyzed to determine if leakage has occurred. A 15-minute urine collection is

---

From the Medical Service and Research Laboratory, Veterans Administration Hospital (Drs. Raisz, Rosenbaum, Prout, and Russell), and the Department of Medicine, Boston University School of Medicine (Drs. Raisz, Rosenbaum, and Prout). Y.; Dr. Rosenbaum at Tufts College Medical School, Boston; Dr. Prout at Johns Hopkins Hospital, Baltimore; and Dr. Russell with the Mount Kisco Medical Group, Mount Kisco, N. Y.

obtained from each kidney for creatinine clearance. Blood for serum creatinine determination is then drawn, phenolsulfonphthalein is injected, and 15-minute phenolsulfonphthalein excretions are measured bilaterally.

Comment

The endogenous creatinine clearance has been widely employed as a measure of glomerular filtration rate. Although it does not measure filtration rate as precisely as inulin clearance, it is much better suited for clinical use because of simplicity and convenience.[3] The urea clearance has also been widely employed as a measure of renal function. Its magnitude represents a variable proportion of glomerular filtration rate, and interpretation is further complicated by the fact that urea clearance varies with the rate of urine flow. Creatinine clearance does not show such variation with urine flow, although a high rate of flow is desirable, as in any clearance procedure, to minimize collection errors. At low rates of flow such errors can be reduced by prolonging the collection period. Moreover, in our experience the chemical determination of urea presents greater difficulty than does that of creatinine.

† Av. creatinine clearance, 126 ml./min.

The mean value for endogenous creatinine clearance obtained in 40 healthy male subjects was 120 ml. per minute, with a standard deviation of ± 15 ml. per minute. A mean value of approximately 100 ml. per minute was obtained in 10 healthy women. The glomerular filtration rate in normal individuals varies with body size, age, and sex.[4] Clearance data are often corrected for body size, using 1.73 sq. m. of body surface area as a standard of reference. This correction need not be made routinely, but the height and weight should be recorded, so that variations in body size can be considered in interpreting the results. The inulin clearance has been shown to decrease with advancing age in normal men free of renal disease. Mean normal values of 90 to 100 ml. per minute per 1.73 sq. m. have been reported in men over 50, and of about 65 ml. per minute per 1.73 sq. m. in men over 80. This variation with age may well hold for creatinine clearance and should be applied to the interpretation of values in older patients.

In normal subjects phenolsulfonphthalein excretion ranges from 25 to 45% in 15 minutes, with a total excretion of 55 to 80% in two hours. The results of this test depend upon the renal plasma flow, the function of the tubule cells, the volume of the distribution of the dye (which is chiefly the blood volume), and, particularly in the 15-minute sample, the amount of delay encountered in the genitourinary tract. The value of a 15-minute sample in detecting minor impairment of function is greatly reduced if bladder emptying is incomplete.[5] To minimize such error, the urine volume should be large. For example, a 10-ml. residual urine volume introduces a 25% error if the volume voided is 30 ml. but only a 5% error if the volume voided is 190 ml. A low 15-minute value with a normal two-hour total suggests that bladder emptying is significantly impaired. Depressions of both 15-minute and two-hour values indicate renal tubular damage or diminished renal blood flow or both and do not distinguish between them.

The administration of a water load of the magnitude employed in the present procedure leads to a diuresis in excess of 8 ml. per minute in normal subjects. The occurrence of such a water diuresis requires an adequate glomerular filtration rate and the ability to form a dilute urine. Inability to secrete a dilute urine is uncommon in renal disease except in patients with advanced failure. However, maximum flow is frequently reduced owing to a decreased rate of filtration. (It is recognized that impairment of water diuresis may occur without primary renal disease, as in adrenocortical insufficiency and certain edematous states. Various antidiuretic stimuli, such as pain, emotional stress, nicotine, and narcotics, also impair water diuresis.) Conversely, the finding of a high maximal urine flow usually indicates that filtration rate is not severely impaired.

The procedure described was not designed as a "screening" test to establish the presence of normal renal function but has been used to evaluate patients with evidence of renal disease. For the former purpose a concentration test[6] is much simpler and has been extensively employed. When significant renal insufficiency is suspected, a concentration procedure requiring fluid restriction may be hazardous.[7] Moreover, it is difficult to estimate the magnitude of renal functional impairment from the results of a concentration test.

The present procedure has been particularly helpful in evaluating patients with normal or only moderately elevated plasma concentrations of nonprotein nitrogen or urea, some of whom may have impaired function as evidenced by creatinine clearance values as low as 25 to 50% of normal. This group includes many hypertensive patients in whom such impairment is of great importance, especially when the use of antihypertensive agents or sympathectomy is under consideration. Although it has been suggested that determination of the plasma creatinine concentration alone will provide adequate evaluation of renal function,[8] in our experience it is not uncommon to find distinct lowering of clearance values with plasma creatinine in the normal range. However, an elevated plasma concentration clearly indicates renal functional impairment. When renal failure is advanced, plasma nonprotein nitrogen, urea, and creatinine concentrations are markedly elevated and further evaluation of renal function is generally superfluous. Moreover, in such patients a large water load may lead to nausea and vomiting, which are particularly to be avoided in renal failure. Water loading is obviously contraindicated in the presence of acute renal failure with oliguria.

Summary

A single procedure for measurement of endogenous creatinine clearance and phenolsulfonphthalein excretion during a water diuresis is a useful adjunct to the clinical evaluation of renal function.

Irving Avenue and University Place, Syracuse 10, N. Y. (Dr. Raisz).

NYSTATIN (MYCOSTATIN) IN THE TREATMENT OF MONILIAL AND NONMONILIAL VAGINITIS

Harry R. Pace, M.D.
and
Samuel I. Schantz, M.D., Brooklyn, N. Y.

• ***Candida albicans infection (moniliasis) was demonstrated by culture in 59 out of 76 patients who had symptoms of vaginitis. Treatment with nystatin, inserted as tablets vaginally at bedtime, cured the moniliasis in 58 cases and failed only in one patient, who did not follow instructions. Of the two case histories given, one illustrates recovery, within two days, of a patient who had been treated for intense pruritus by various other means for several months; the other patient developed moniliasis after intensive treatment with antibiotics for pelvic inflammatory disease and recovered from moniliasis promptly after administration of nystatin. The infection recurred in 14 cases but was eradicated by a second course of treatment. Nystatin was not effective as a rule in trichomoniasis, but in moniliasis it relieved the pruritus promptly and did not cause any side-effects.***

Vaginal discharge, whether a primary or secondary symptom, is the most common pelvic complaint encountered in office practice. When a patient comes in complaining of vaginal itch accompanied by leukorrheal discharge, the symptoms usually are caused by either monilial (Candida albicans) vaginitis or trichomonal vaginitis. Leukorrhea due to nonspecific causes as well as to endocervicitis is not associated with pruritus. In the past, trichomonal vaginitis has had an appreciably higher incidence than monilial vaginitis. Now, however, monilial vaginitis is the more common of the two conditions. This reversal in incidence undoubtedly reflects to some extent the improved methods of diagnosis in vaginal moniliasis, but it is worth noting that this ratio has reversed since the development of antibiotics. Lee and Keifer [1] report that, prior to the advent of antibiotics, the usual office practitioner encountered four cases of trichomoniasis for every one of vaginal moniliasis; today, nearly a decade later, he finds three cases of monilial vaginitis for each case of trichomonal vaginitis. This ratio would seem too low in our experience. In our series of unselected office patients reported here, we found that the ratio of trichomonal vaginitis to monilial vaginitis in nonpregnant patients was 1:7. Among pregnant patients this ratio was 1:15. Many patients who appeared clinically to have trichomonal vaginitis were later shown to have monilial vaginitis.

Vaginal moniliasis has always posed a therapeutic problem. Heretofore, gentian violet has served as the principal therapeutic agent for this troublesome and often stubborn infection. However, gentian violet, as well as some of the gentian variants, not only is somewhat undependable but frequently produces irritation. In addition, the patient dislikes its staining property, and she also finds gentian violet difficult to apply correctly by herself. Various other preparations have been employed, but none has provided consistently satisfactory therapy.

Recently an antifungal antibiotic said to be both fungicidal and fungistatic for C. albicans has been introduced.[2] This agent, Mycostatin or nystatin, the now-accepted generic name assigned it by its discoverers, Hazen and Brown,[3] is derived from Streptomyces noursei. Shown to have extremely low toxicity, nystatin is also remarkably free of side-effects.[4] Because of these properties, it was decided to try nystatin in the treatment of vaginitis, and, so that it could be easily and conveniently inserted by the patient herself, it was used in the form of a tablet for vaginal insertion.

Clinical Material

The series here presented consists of 76 consecutive unselected cases of vaginitis encountered in office practice. The presenting complaints in all patients were leukorrhea and pruritus. These symptoms were severe in 28 women, moderate in 47, and mild in one patient. Vaginal smears from all 76 women were cultured for C. albicans, and in all cases a search was made (using the hanging-drop method with sodium chloride solution and the diagnostic aid, Trichomonas Diluent) for Trichomonas vaginalis. None of the patients proved to have both trichomonal vaginitis and monilial vaginitis. Mixed vaginal infections by C. albicans and T. vaginalis have not been observed by us, and it is our belief that such cases are extremely rare. Those reported may represent an error in diagnosis, since clinically there is some similarity in the conditions. Such errors can be avoided by basing the diagnosis on the results of culture.

Nickerson's medium was used exclusively for culturing of specimens for C. albicans. The active ingredient of this medium is a complex polybismuth sulfite. Culturing with Nickerson's medium, which has been well described in detail by Perl and co-workers,[5] is uncomplicated and can be adopted as a routine office procedure. As regards obtaining the material for culture, three points warrant emphasis. First, the patient should be instructed that she is neither to douche nor to use any medicament intravaginally for 72 hours prior to the taking of material for culture. Second, material for culture from the vagina should be obtained with a sterile, cotton-tipped applicator introduced through a sterile, nonlubricated bivalve speculum. In the absence of cheese-like particles in the vagina or on the vulva, a specimen should be taken from the secretion between the rugae of the lateral vaginal walls and at the mucocutaneous borders of the introitus. Third, cervical secretions are of no value in determining the presence of Candida organisms by culture.

Culturing presents no problems. The culture can be kept at either room or incubator temperature. If kept at room temperature, the observation period is two to five days. However, nystatin therapy can and should be started immediately, rather than delayed until the results of culture are known. If the culture is incubated at 32 to 37 C (89.6 to 98.6F), the result can be obtained within 24 to 48 hours. A positive culture will show C. albicans growing in large, jet black or dark brown, shiny, hemispherical colonies. On continued incubation, peripheral filamentation is revealed. Because of the ease and accuracy of culturing with Nickerson's medium, we prefer it to other mediums.

A total of 59 patients proved to have monilial (C. albicans) vaginitis. Thirty-one of these women were pregnant and 28 nonpregnant. Three of the nonpregnant patients, it is interesting to note, had received antibiotic therapy prior to the onset of monilial vaginitis. In every case the diagnosis of monilial vaginitis was confirmed by culture. Evaluation of nystatin therapy was based on clinical improvement and the results of cultures obtained at two follow-up examinations. The first examination was made one week after the institution of therapy and the second examination two to three months later.

In all patients therapy consisted solely of vaginal insertion of nystatin tablets, each containing 100,000 units of nystatin. No douches were prescribed or used during therapy, primarily because we do not consider the vaginal pH an important factor and consequently felt it unnecessary to attempt alteration of the pH with acid or alkaline douches. Therapy was not discontinued during menstruation. Three different dosage schedules were employed. All patients were instructed to insert the tablet just before retiring; when 2 tablets were ordered, they were to be used together, rather than one at night and one in the morning. Of the 31 pregnant women, 26 were instructed to use 1 tablet nightly for 7 nights, 2 were to use 1 tablet nightly for 14 nights, and the remaining 3 were to use 2 tablets nightly for 7 nights. Among the 28 nonpregnant patients, 12 were to use 1 tablet nightly for 7 nights, 5 were to use 1 tablet nightly for 14 nights, and 11 were to use 2 tablets nightly for 7 nights.

2 tablets daily for 7 days	3	2		1		1	3
Totals	31	28	1	1	1	10	31

Results in Vaginal Moniliasis

Intravaginal therapy with nystatin was successful in 98.3% of the 59 patients with vaginal moniliasis. Clinical manifestations disappeared and cultures became negative in all but one patient. Relief from pruritus was obtained within 48 hours in all cases. When the results in pregnant and nonpregnant patients are considered separately, it is seen that 100% of the pregnant patients and 96.3% of the nonpregnant patients responded favorably. The single patient who failed to respond to therapy used the medicament for only one week and thereafter failed to comply with instructions. We consider this failure to be due to lack of cooperation on her part. The above results are final, as determined by culture and clinical improvement at the follow-up examinations two to three months after initiation of therapy. Tables 1 and 2 show these final results and also present the early results, which were evaluated on the basis of clinical improvement and cultures obtained after one week of therapy. These tables also indicate the dosage schedule and the number of patients who had recurrences.

Table 2.—*Results of Treatment with Nystatin in Twenty-Eight Nonpregnant Patients with Vaginal Moniliasis*

Dosage	Patients, No	Results, Early		Recurrences Patients, No	Results, Final Excellent
		Excellent	Poor		
1 tablet daily for 7 days	12	11	1	2	11
1 tablet daily for 14 days	5	5		1	5
2 tablets daily for 7 days	11	11		1	11
Totals	28	27	1	4	27

Recurrence was indicated by reappearance of symptoms and positive cultures. In patients with recurrences, the interval between the cessation of therapy and recurrence ranged from two to five weeks. There did not appear to be any relationship between the severity of symptoms and recurrence; however, both the therapy schedule employed and pregnancy did appear to have some bearing on recurrence. Seventy-nine per cent of the relapses occurred in patients who used 1 tablet for seven days; or, expressed another way, 29% of the patients who were on this particular schedule had a recurrence. Further experience with nystatin will no doubt enable us to set up therapy schedules closer to the optimum.

Report of Cases

Two cases are presented for illustration. One patient had monilial vaginitis of long standing that was refractory to all forms of treatment except with nystatin. The second patient presented symptoms subsequent to intensive antibiotic therapy.

Case 1.—This woman had been suffering from intense vaginal itching for several months, during which time she had tried several forms of gentian violet, various douches, and other preparations, with intermittent partial relief. She became pregnant and presented herself at our office six weeks later. Culture for Candida was strongly positive within 24 hours, and nystatin therapy was started. Within two days she remarked that she had never felt so free of her symptoms, and subsequent cultures remained negative.

Case 2.—This woman had had a total hysterectomy and bilateral salpingo-oophorectomy for multiple uterine fibroids associated with chronic pelvic inflammatory disease. During the postoperative period she developed a pelvic abscess that was treated with intensive antibiotic therapy and subsequently drained from below. Shortly after discharge from the hospital she presented herself at our office complaining of severe vaginal pruritus. Culture for Candida was positive, and she was immediately given nystatin tablets to insert. Her condition cleared up within two days, and subsequent cultures were negative.

Results in Nonmonilial Vaginitis

Seventeen of the patients in this series of 76 were found to have nonmonilial vaginitis. Six had trichomonal vaginitis and were also treated with nystatin tablets to be inserted vaginally on the same therapy schedules. Two of these patients were pregnant, and in one of these an excellent early and final result was obtained. In the other patient, however, early results were poor, and she ultimately required other therapy. Of the four nonpregnant patients, two obtained no relief and were immediately started on other therapy. In the other two patients, early results were fair in one and poor in the other. Other therapy was subsequently employed. Cultures from the remaining 11 patients were all negative for both C. albicans and T. vaginalis. In nine, the early results with nystatin were poor, and all were placed on another form of therapy. Two women had a good early response to nystatin; in one of these the final result was excellent, while in the other the final result remained good. The results in these cases of nonmonilial vaginitis add to the evidence that nystatin is specific for C. albicans infections.

Comment

Although the pH of the vagina is held by many to be an important factor in the development of moniliasis,[6] we have not found this to be true. So far as could be determined, the pH played no part in the production of vaginitis in any of the patients in this series. Theoretically, a normal pH would favor the development of fungal infections, since fungi, in vivo as well as in vitro, grow best in an acid environment. However, an increase in the pH may be followed by *clinical moniliasis*. A high glycogen content in the vaginal mucosa has also long been regarded as a predisposing factor in fungal infection. Indeed, it is this increased glycogen content that is presented as the reason for the larger incidence of vaginal moniliasis in pregnant women or in women with diabetes. The exacerbations sometimes seen in the premenstrual phase are also accounted for by the increased amount of glycogen then present in the vaginal mucosa.[7]

Our experience would suggest that the importance of both the pH and the glycogen content is perhaps overemphasized. The cases making up this series were almost equally distributed between pregnant and nonpregnant women. Furthermore, there did not appear to be any correlation between the phase of the menstrual cycle and the onset or exacerbation of symptoms. Reinvestigation of the relationship between increased glycogen content in the vaginal mucosa and the production of monilial vaginitis may be justified. Perhaps appropriate studies would result in the identification of other factors operative in the development of vaginal moniliasis.

Summary

In a series of 76 consecutive cases of vaginitis encountered in office practice, 59 were proved by culture to be caused by Candida albicans. Six cases were caused by Trichomonas vaginalis, and 11 were due to neither monilial nor trichomonal infections. The ratio of trichomonal vaginitis to monilial vaginitis was 1:7 in nonpregnant patients and 1:15 in pregnant patients. All 59 patients with vaginal moniliasis, 31 of whom were pregnant and 28 of whom were nonpregnant, were treated with nystatin (Mycostatin), a new antifungal agent. Therapy with nystatin tablets, inserted vaginally, was successful in 98.3% of these 59 patients with vaginal moniliasis; that is, an excellent result was obtained in 100% of the pregnant patients and in 96.3% of the nonpregnant patients. Therapeutic response was judged on the basis of clinical improvement and of the results of cultures obtained at follow-up examinations. Ten pregnant patients and four nonpregnant patients with monilial vaginitis had recurrences, as determined by culture and clinical manifestations, two to five weeks after the cessation of therapy. Repeat courses of nystatin gave excellent final results in all 14 of these women. Relief from pruritus caused by vaginal moniliasis was obtained within 48 hours of the institution of nystatin therapy. Nystatin proved effective in the treatment of only 2 of the 17 cases of nonmonilial vaginitis. There was no

evidence of any form of drug toxicity in any of the cases. The vaginal pH and glycogen content do not appear to be predisposing factors in vaginal moniliasis.

Addendum

Since the preparation of this report, five additional patients with proved monilial vaginitis have been treated with nystatin tablets. All five patients obtained excellent early and final results.

4611 12th Ave. (19) (Dr. Pace).

The nystatin used in this study was supplied as Mycostatin by E R Squibb & Sons, New York

EFFECTS OF 3,5,3′ L-TRIIODOTHYRONINE IN PATIENTS WITH METABOLIC INSUFFICIENCY

PRELIMINARY REPORT

C. Robert Tittle, Abington, Pa.

• *A general slowing down of metabolic processes usually is associated with subnormal thyroid activity, but it can also be seen in cases where the thyroid is normally active as judged by its ability to take up radioactive iodine and by the levels of cholesterol and protein-bound iodine in the blood. The latter type of case is marked by differences in the effect of certain medicaments upon the patient. Eight patients are here described because their signs and symptoms of metabolic insufficiency were not relieved by protracted medication with desiccated thyroid preparations. Six of them improved subjectively and objectively when treated with 3, 5, 3′ L-triiodothyronine. The dosage had to be adjusted to the individual patient, but in general 50 mcg. per day was safe and effective Since this drug not only is effective and rapid but also differs from desiccated thyroid in its site of action, it is valuable in the treatment of metabolic insufficiency*

The effects of thyroid dysfunction on metabolism have long been recognized, even though the exact mechanisms are still unknown. In hypothyroidism, when the gland is absent or not functioning properly, the metabolic rate in various organ systems of the body is depressed.[1] Such depression results in symptoms of myxedema and in lethargy, emotional instability, dulness, and other "slowing down" processes. Moreover, the depression can be measured by basal metabolic rate tests and confirmed by serum protein-bound iodine and radioactive iodine (I^{131})—uptake tests that indicate a reduced output by the thyroid gland.[1]

Besides occurring in hypothyroidism, metabolic depression is known to exist also in patients who apparently have normal thyroid function.[2] Such patients show symptoms and physical signs that often mimic hypothyroidism, and they have a low-normal or subnormal basal metabolic rate (below -20%). At the same time, however, they have normal protein-bound iodine levels, I^{131} uptake, and cholesterol values, in other words, they have normal thyroid gland function A very small portion of these particular patients may have hypopituitarism, nephrosis, malnutrition, hypogonadism, adrenal cortical hypofunction (Addison's disease), or some other disorder. When these known causes for metabolic depression are excluded, however, there still remains a group of patients who show signs and symptoms due to a specific disorder. metabolic insufficiency or hypometabolism[3]

Since the discovery of 3,5,3′ L-triiodothyronine by Gross and Pitt-Rivers,[4] various investigators[5] have reported findings that seem to explain how a subnormal basal metabolic rate can coexist with apparent normal function of the thyroid gland. Specifically, these findings have suggested that, in the patient with metabolic insufficiency, thyroid products cannot properly be utilized in metabolic processes at the tissue level Freedberg and others,[2b] Lee,[6] and Kirk and Kvorning[7] have reported that patients with this disorder generally do not show symptomatic or metabolic responses to thyroid extract, thyroglobulin, or thyroxine. Such patients, however, have responded to treatment with L-triiodothyronine after failing to do so with thyroid preparations.[2] Because of these favorable reports, I undertook the present study to evaluate the clinical efficacy of L-triiodothyronine. The aims of the study were (1) to evaluate symptomatic and metabolic responses to L-triiodothyronine and (2) to compare these responses with those obtained with desiccated thyroid in previous treatments.

Assistant Professor, Metabolic Diseases, Graduate School of Medicine, University of Pennsylvania, Philadelphia, and Visiting Physician, Endocrine Clinic, Abington Memorial Hospital

Material and Method

Of eight patients (five females and three males) between the ages of 22 and 55 years given a diagnosis of metabolic insufficiency, all had basal metabolic rates between −28 and −36% on at least two repeated tests. None showed signs of metabolic depression attributable to malnutrition, psychoneurosis, anorexia nervosa, adrenal insufficiency, nephrosis, or other known disorders. Symptoms and physical signs seen in the group were chronic fatigability, stiffness of muscle and joint, sensitivity to cold, constipation, obesity, facial puffiness, dry hair and skin, and general lassitude. All the patients had been treated previously with 2 to 3 grains (0.13 to 0.19 gm.) of desiccated thyroid per day for as long as six months to five years before this study. With this therapy, however, none had gained more than transient, moderate relief of symptoms and none had shown a significant rise in basal metabolic rate (table 1).

Before L-triiodothyronine was given, desiccated thyroid was withdrawn from each patient for from one to five months. At the end of this rest period, basal metabolic rates ranged between −28 and −36%. Other thyroid function values, however, were within normal limits. Protein-bound iodine levels by the Barker method[8] ranged from 3.5 to 5.2 mcg. per 100 ml.; fasting serum cholesterol levels, from 186 to 240 mg. per 100 ml.; 24-hour I^{131} uptake (measured in four patients) ranged from 33 to 40%. In six patients, values of 24-hour excretion of neutral 17-ketosteroids, assayed by the Holtorff-Koch modification of the Zimmerman reaction, ranged from 9.2 to 14.8 mg. L-triiodothyronine was administered initially in doses of 12.5 to 25 mcg. daily; the dosage was then increased by 12.5 or 25 mcg. daily every two weeks. Maximum doses ranged between 50 and 100 mcg. daily (table 1). After four to eight weeks, basal metabolism tests were repeated. In three patients who were treated for a longer time, the basal metabolic rate was remeasured after several months.

Results

Symptomatic and metabolic responses were observed in six of the eight patients during one to two months of treatment with L-triiodothyronine (table 2). Symptoms of fatigue and of aching and stiffness in muscles and joints disappeared completely in the six patients who responded; in some patients, symptoms of constipation, sensitivity to cold, obesity, and facial puffiness also subsided or disappeared. During the same period, the basal metabolic rates in six of the eight patients rose to −16% or higher. The average elevation was 18%; the range, 16 to 20% (table 1 and figure). Two patients who had been hypersensitive to desiccated thyroid did not show metabolic or symptomatic responses to 50 mcg. of L-triiodothyronine daily. Typical responses are illustrated in three case histories below. The first describes a patient who showed a favorable response; the second, a patient who did not respond; and the third, a patient who responded but then had a relapse when the drug was voluntarily withdrawn.

CASE 1.—A patient, a 48-year-old male, had shown symptoms of fatigue, muscular aches, facial puffiness, loss of hair, sensitivity to cold, brittle nails, and obesity for three years. His basal metabolic rate in July, 1954, was −32%. During the year that followed, he was treated with up to 3 grains of desiccated thyroid daily with only transient relief of symptoms; he could not tolerate higher doses. In July, 1955, his basal metabolic rate was −34%. Desiccated thyroid was withdrawn, and in August, 1955, his basal metabolic rate was −32%; the protein-bound iodine level, 3.5 mcg. per 100 ml.; and I^{131} uptake, 33%. L-triiodothyronine was given in increasing dosage up to 62.5 mcg. daily. After one month (in September, 1955) his basal metabolic rate had risen to −16%. He had lost 6 lb. and reportedly "was able to perform a full day's work as a school principal for the first time in three years" because of the disappearance of fatigability, the clearing up of muscular pains in his legs, and the loss of a feeling of depression that had previously developed toward the latter part of his working day. Symptoms of facial puffiness and sensitivity to cold had also subsided. Three months later, on therapy with 50 mcg. of L-triiodothyronine daily, his basal metabolic rate was −12% and he remained improved.

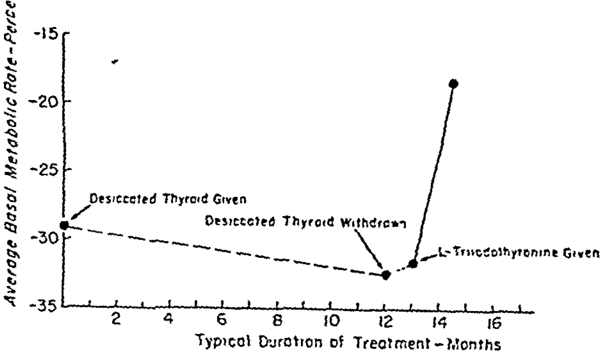
CASE 2.—A 28-year-old female patient had shown symptoms of inability to gain weight, chronic fatigability, constipation, sensitivity to cold, brittle nails, and arthralgic pains ever since adolescence. In November, 1953, her basal metabolic rate was −36%. For six months following that time, she was given up to 2 grains of desiccated thyroid daily, without relief of symptoms. Doses higher than this caused her to become nervous and irritable, and she developed palpitations. After six months, her basal metabolic rate was still −36%, and desiccated thyroid had to be withdrawn. In July, 1955, her basal metabolic rate was −28%; protein-bound iodine level, 5.2 mcg. per 100 ml.; and I^{131} uptake (24 hour), 33%. She was given L-triiodothyronine in increasing doses up to 50 mcg. daily for one month. During this time, she felt less fatigued but showed signs of increased nervousness, insomnia, and palpitations, so the drug was withdrawn. Her basal metabolic rate was −30% at this time.

Table 2.—*Symptomatic Responses in Six Patients During Four to Eight Weeks of Treatment with L-Triiodothyronine*

Symptoms	No. of Cases After Treatment with Desiccated Thyroid	No. of Patients Responding to Treatment with L-Triiodothyronine
Chronic fatigue	6	6
Muscle or joint aching, stiffness	6	6
Sensitivity to cold	4	2
Constipation	4	1
Obesity	4	1
Brittle nails	3	0
Facial puffiness	3	2

Case 3.—A 28-year-old female reported symptoms of fatigue, facial puffiness, muscular aches, constipation, and sensitivity to cold that had persisted for two years. In April, 1954, her basal metabolic rate was −32%. She was treated with 2 grains of desiccated thyroid daily for one year and could not tolerate higher doses due to palpitation and insomnia. After one year (in April, 1955) her basal metabolic rate was −34%. Desiccated thyroid was withdrawn, and after one month her protein-bound iodine level was 5.2 mcg. per 100 ml.; and I^{131} uptake (24 hour) was 40%. She was given L-triiodothyronine in increasing doses up to 62.5 mcg. daily. After two months (in September, 1955) her basal metabolic rate had risen to −16% and all of her symptoms had subsided. Because she felt so improved, she voluntarily discontinued medication. Within two weeks, symptoms of fatigue and muscular aching reappeared, and her basal metabolic rate had dropped to −24%. Treatment with L-triiodothyronine was resumed, and in one month her basal metabolic rate had risen to −14% and her symptoms of fatigue and muscular aching had subsided. She reportedly "felt so lively again and complained so little of fatigue" that her husband "wanted her never to discontinue the drug again."

Two patients (cases 7 and 8, table 1) who had been hypersensitive to desiccated thyroid developed insomnia, palpitation, and increased nervousness while taking 50 mcg. of L-triiodothyronine daily. In these cases, therapy was discontinued. Two other patients (cases 1 and 4, table 1) showed moderate palpitations while taking L-triiodothyronine; in one, side-reactions were not severe enough to warrant discontinuing use of the drug; in the other, side-reactions were eliminated by reducing the dosage from 75 mcg. daily to 37.5 mcg. daily, although a decrease in basal metabolic rate resulted. Dosage in the latter case had to be adjusted gradually to an intermediate level. Side-reactions, when they occurred, disappeared within several days after the use of the drug was discontinued or the drug was reduced in dosage. Of all the six patients who responded to treatment, conditions of none have shown signs of becoming refractory after two months of treatment with L-triiodothyronine. Three have been treated for as long as four months without their conditions becoming refractory to the drug.



The effects of desiccated thyroid and L-triiodothyronine on basal metabolic rates of patients with metabolic insufficiency (average response in eight patients).

Comment

All of the patients in this study had normal protein-bound iodine levels, and four were known to have normal I^{131}-uptake values. Therefore, it was concluded that the thyroid function in these patients was normal and that the output of their thyroid glands should have been adequate for proper metabolism. There was, then, some defect other than hypothyroidism responsible for their subnormal basal metabolic rates and for their clinical symptoms. Patients with this disorder reportedly do not usually respond to treatment with desiccated thyroid, thyroid extract, or thyroxine.[9] When the basic nature of the disorder is considered, however, the reason for this unresponsiveness is clear. If a patient has a deficient thyroid function, as evidenced by low protein-bound iodine level and low I^{131} -uptake values, he could be expected to respond to hormonal replacement therapy because he has a shortage of thyroid products. On the other hand, if a patient has a low basal metabolic rate but normal protein-bound iodine and normal I^{131} -uptake values, his disorder is not caused by lack of thyroid products, so he would not be relieved by hormonal replacement therapy. Indeed, this was true in the eight cases reported here: all the patients had been treated with desiccated thyroid for six months to five years without symptomatic response or elevation of basal metabolic rate.

Several reasons for the failure of thyroid replacement therapy to relieve metabolic insufficiency have been suggested in the literature. Reiss and Haigh[10] have proposed that there may be a defect in some patients that is due to insensitivity of the body tissues to thyroid hormone. Winkler and others[11] have suggested that perhaps the thyroid hormone is destroyed, stored, or rapidly inactivated in such patients. Freedberg and his associates[2] have suggested the possibility of a defect in the transformation of thyroxine to a more active form or an impermeability of the tissues to thyroxine.

The results of the present study have proved that L-triiodothyronine is definitely effective in treating patients with metabolic insufficiency who do not respond to desiccated thyroid. Considering the theoretical reasons above, it appears that L-triiodothyronine bypasses the specific defect involved, it may be more readily absorbed at the tissue level than desiccated thyroid is, or it may stimulate metabolic processes more efficiently.

It is interesting that, during treatment with desiccated thyroid, the basal metabolic rate of seven of the eight patients had dropped to slightly lower than pretreatment levels (table 1 and figure). These drops, which are statistically significant at the 0.01 level, may have been due to experimental error, a weight gain in the patients that would affect the calculation but not the total oxidation process, or a gradual worsening of the patients' metabolic processes with passing of time, since use of desiccated thyroid was not correcting the basic disorder. Inasmuch as identical techniques were used in all basal metabolic rate measurements, and since not all patients gained weight during treatment with desiccated thyroid, the last explanation seems the most likely. If any particular treatment is ineffective, the disorder will probably become more severe, as it may have become in these patients. Proof for the supposition, however, could not be found from the present laboratory and clinical data.

Summary and Conclusions

This study has demonstrated the effects of 3,5,3′ L-triiodothyronine in eight patients with metabolic insufficiency. Despite treatment with desiccated thyroid for six months to five years, each of the patients had symptomatic and physical abnormalities due to metabolic depression. The basal metabolic rates of the group ranged between −28 and −36%, although other thyroid function values were normal. Serum protein-bound iodine levels ranged between 3.5 and 5.2 mcg. per 100 ml.; serum cholesterol levels varied from 186 to 240 mg. per 100 ml. I^{131}-uptake values, measured in four patients, were also normal.

L-triiodothyronine was administered in increasing dosages until maximum doses of 50 to 100 mcg. daily were reached. Within one to two months, symptoms of chronic fatigue and aching in muscles and joints disappeared in six of the eight patients. Improvements ere also noted in weight, bowel function, and thermal gulation. Concomitantly, the basal metabolic rates in the six patients responding were elevated to −16% or higher. The average elevation was 18%, the range 16 to 20% above values measured after treatment with desiccated thyroid. Two of the patients with marked sensitivity to desiccated thyroid developed insomnia, increased nervousness, and palpitations while taking 50 mcg. daily of L-triiodothyronine. When the drug was withdrawn, however, the effects of overstimulation disappeared within several days. Two other patients, taking 75 mcg. daily, showed mild signs of overstimulation, but therapy was not discontinued. The remaining patients tolerated L-triiodothyronine satisfactorily.

In summary, L-triiodothyronine produced satisfactory symptomatic and physical improvement and elevation in basal metabolic rate. It is concluded, therefore that L-triiodothyronine is a rapid and effective metabolic stimulant and therapeutic agent for treating metabolic insufficiency. Further studies with this compound are warranted.

CLINICAL NOTES

THE ANTIGRAVITY SUIT (G-SUIT) IN SURGERY

CONTROL OF BLOOD PRESSURE IN *THE SITTING* POSITION AND IN HYPOTENSIVE ANESTHESIA

W. James Gardner, M.D.
and
Donald F. Dohn, M.D., Cleveland

To meet the needs associated with high-speed flying, aviation medicine has developed an inflatable suit to be used for the prevention of blackouts that afflict the flyer when he pulls his plane sharply out of a fast dive. Because these suits were designed to counteract the force of gravity, which is multiplied many times during such maneuvers, they became known as antigravity suits or, more simply, as g-suits. The standard aviation garment consists of inflatable leggings and an abdominal binder, which, by constricting the lower part of the body, prevent pooling of blood. Wood and his co-workers [1] demonstrated the effectiveness of the g-suit in observations in the human centrifuge. Restall and Smirk [2] applied the principle to the study of hypotension produced with hexamethonium, while Seiker and his associates [3] described its mode of action in cases of postural hypotension occurring after sympathectomy.

For several years we employed an aviation antigravity suit to prevent postural hypotension during certain neurosurgical operations carried out with the

From a paper read before the Harvey Cushing Society, Honolulu, T. H., April 16-18, 1956.

patient in the sitting position. The suit was put on the patient before he was placed in the chair, and, if a fall in blood pressure occurred during the operation, it could be combated by inflating the suit from a tank of gas. The disadvantage of the standard aviation garment, however, lay in the fact that it was awkward to put on the patient; therefore, unless the need could be clearly anticipated, it was not employed.

For this reason, a more easily applied g-suit was devised. It consists merely of two sheets of vinyl plastic sealed at the edges to form a large inflatable bladder. This is placed beneath the patient, the edges are folded over so as to enclose him from the rib margin to the ankles, and it is drawn snug by lacing. A manometer is attached to a tube leading from the upper part of the bladder; to a second tube leading from the lower end, a tank of gas is attached from which the bladder may be inflated in a matter of seconds (fig. 1). This suit has an advantage over the above-described aviation garment in that it also compresses the pelvic area and buttocks. Experience with this g-suit has shown that it is not necessary to enclose the legs separately to obtain the desired hemodynamic effect, that pressures in excess of 20 mm. Hg are seldom indicated, and that reduction of vital capacity does not result with pressures up to 40 mm. Hg.

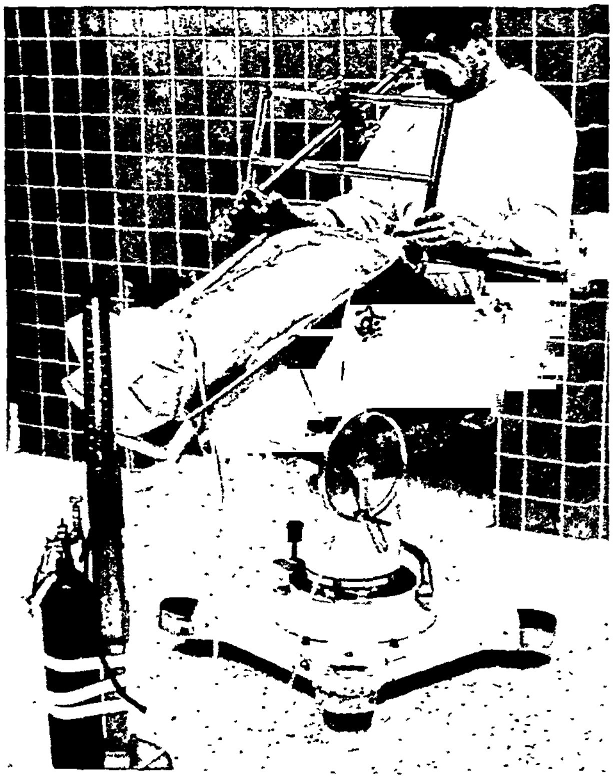

Fig. 1.—G-suit on patient in sitting position.

The efficacy of this type of g-suit was demonstrated in a diabetic patient with severe postural hypotension. This patient could not sit up without fainting. She was placed on a tilt table, and the g-suit was put on her. With the patient in the horizontal position, the intra-arterial pressure was recorded at 130/80 mm. Hg. When the table was tilted so that the head elevated 55 degrees above the horizontal, the blo pressure immediately fell to 50/20 mm. Hg, and the patient complained of feeling faint. The g-suit was then inflated to a pressure of 10 mm. Hg, and the blood pressure immediately was raised to 115/60 mm. Hg. The pressure in the g-suit was released, and the systolic blood pressure fell to a level below 50 mm. Hg. When the g-suit was again inflated to 10 mm. Hg, the blood pressure again rose to 115/60 mm. Hg (fig. 2).

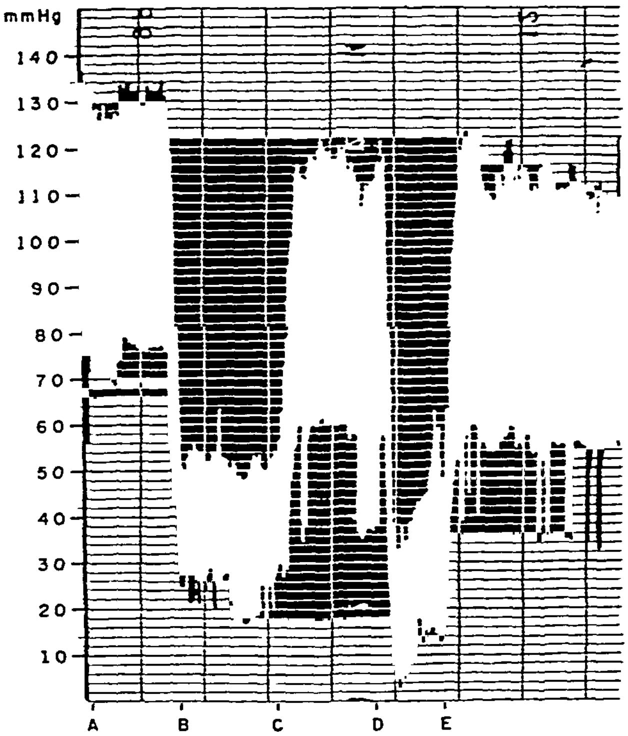

Fig. 2.—Intra-arterial recordings of blood pressure levels of patient with postural hypotension, taken with patient on tilt table; *A*, patient in horizontal position; *B*, patient's head raised 55 degrees; *C*, suit inflated to 10 mm. Hg, *D*, pressure in suit released; *E*, suit reinflated to 10 mm. Hg.

This suit has proved to be of value in cordotomies carried out with the patient in the sitting position, because in this operation the sympathetic pathways in the cord may be interrupted, resulting in the immediate development of postural hypotension (fig. 3). The g-suit has been helpful in overcoming the syncope in the sitting position that sometimes is observed in patients operated on under local anesthesia for herniation of the nucleus pulposus in the cervical region. Another advantage is that the increased venous filling that the g-suit creates decreases the possibility of air embolism during operations with the patient in this position.

The suit is useful also in operations with the patient in the supine position, when hypotension is to be induced either by drugs, by spinal anesthesia, or by bleeding (fig. 4). In this position, if the operating table is tilted so that the head is elevated, the hypotensive methods are more effective; and, in case the mark is overshot, the fall in blood pressure may be countered by inflating the g-suit. Inflation of the proved helpful when, toward the end of it is desired to raise the blood p porarily in order to determine whether hemostasis will be satisfactory when the effect of the hypotensive drug has been dissipated.

In a search of the literature for medical applications of the g-suit principle, it was discovered that Crile described a pneumatic suit in 1903.[1] His suit was constructed of a double layer of specially made rubber, and, when put on the patient and inflated by means of a bicycle pump, it exerted a uniform pressure upon the surface of the body and extremities. It constituted, in Crile's words, "an artificial peripheral resistance." The suit was used for the purpose of maintaining the blood pressure during operations on the head and neck with the patient in the semisitting position. He described the effect of the suit in restoring the blood pressure in several cases of serious blood loss during operations, but its use was plagued with technical failures because of the tendency for the suit to "spring a leak." In 1909, Crile[5] described a dramatic response in a case of hemorrhagic shock in these words:

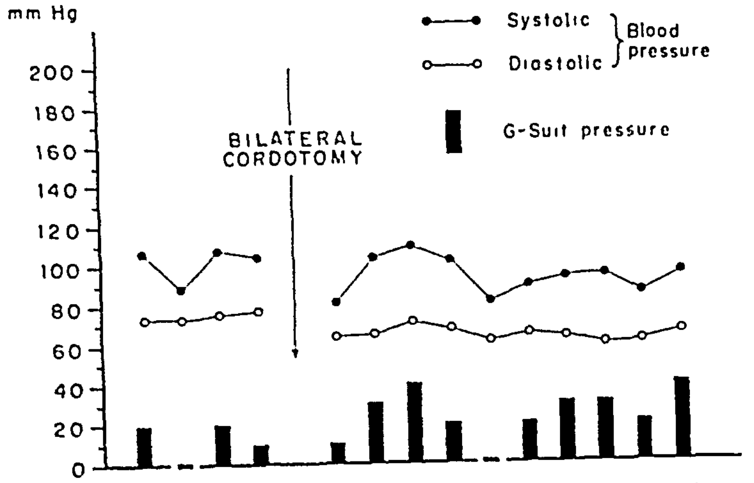

Fig. 3.—Blood pressure levels of patient with postural hypotension during cordotomy, with patient in sitting position.

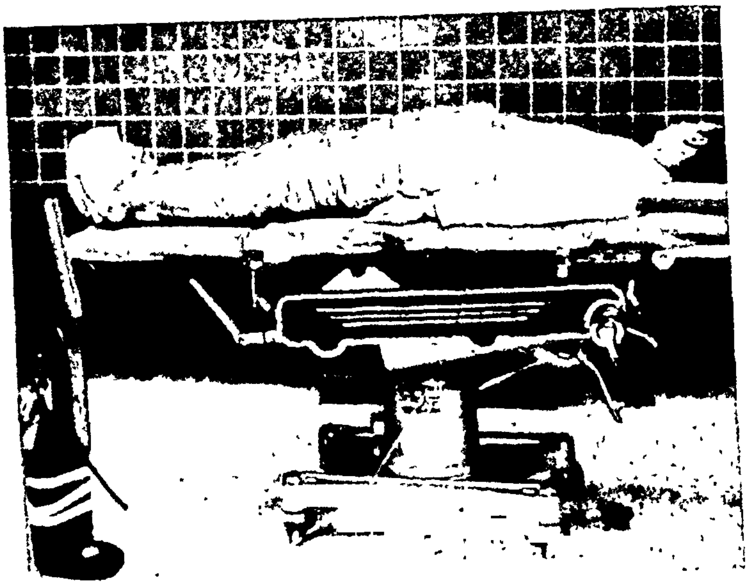

Fig. 4.—G-suit on patient in horizontal position

> A cut-throat patient was admitted to the wards of Lakeside Hospital, exsanguinated and pulseless. Saline infusion and stimulants had been given in maximum amounts during twelve hours, but the circulation always relapsed, and at the time of the application of the rubber suit the pulse was barely perceptible, the respiration gasping, and the patient unconscious. On applying firm pneumatic pressure up to the costal borders the pulse became immediately better, the blood pressure rising to 110 mm of mercury, and consciousness was regained. The suit was worn for twelve hours, when the condition had sufficiently improved to warrant a gradual decompression. Recovery followed.

This work of Crile's probably represents the earliest application of the principle of the modern aviation antigravity suit. It appears likely that Crile gave it up because of technical difficulties when improved methods made transfusion a safe procedure. We have recently seen two striking examples of the effectiveness of this principle in the treatment of hemorrhagic shock. Because of the multiplicity of factors involved in these cases, they will be described in a separate communication.

Summary

The principle of the antigravity suit (g-suit) used in aviation is effective in combating postural hypotension during operations with the patient in the sitting position. It is also helpful in the management of induced hypotension during operations with the patient in the supine position. A simplified g-suit, consisting of a plastic bladder, may be wrapped about the lower part of the body and inflated from a tank of gas. Crile applied this principle to the control of blood pressure during surgery more than 50 years ago.

2020 E. 93rd St. (6) (Dr. Gardner).

Use of Digitalis Before Surgery.—Digitalis is frequently used prophylactically in patients known to have paroxysms of cardiac arrhythmias. Thus it is well to digitalize an elderly patient in preparation for surgery if such a patient should give a history of previous bouts of auricular fibrillation or flutter. Patients with mitral stenosis in whom surgery is indicated should receive digitalis prior to surgery because of the high incidence of supraventricular arrhythmias during the operation or the post-operative period. On the other hand, the use of digitalis to prevent heart failure in individuals who have no signs of failure but merely enlarged hearts is not recommended because there are no physiologic data to support it. Many investigators over the years have repeatedly shown that cardiac output of both normal individuals and those with cardiomegaly is either unchanged or decreased upon digitalization. In fact, in some cases the decrease was up to 36 per cent. In addition, physiologic studies failed to show a change in venous pressure, mean auricular pressure, or right ventricular pressure. As Harvey has pointed out, these studies do not answer the question of prophylactic digitalization. The information which would be pertinent is the manner in which digitalization increases cardiac output under stress of exercise or operation. At present such information is not available.—T. Koppanyi, Ph.D., and J. J. Leonard, M.D., Cardiac Glycosides, *Medical Annals of the District of Columbia*, April, 1956.

GRADUATE MEDICAL EDUCATION IN THE UNITED STATES

ANNUAL REPORT AND DIRECTORY OF APPROVED INTERNSHIPS AND RESIDENCIES IN THE UNITED STATES: ANNUAL REPORT ON APPROVED TECHNICAL SCHOOLS IN THE UNITED STATES, AND RÉSUMÉ OF CHANGES IN THE REQUIREMENTS OF EXAMINING BOARDS IN THE MEDICAL SPECIALTIES

PREPARED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF
THE AMERICAN MEDICAL ASSOCIATION

Arthur N. Springall, M.D., John Hinman, M.D., and Willard V. Thompson, M.D.

ANNUAL REPORT

The Council on Medical Education and Hospitals presents this 30th Annual Report on Internships and Residencies, which consists of statistical data and other information on training programs for interns and residents conducted in hospitals approved by the Council. All hospitals listed are located in the continental United States or in its territories and possessions (the Canal Zone, Hawaii, and Puerto Rico). The report is composed of descriptive material; statistical tables and graphs; information on the National Intern Matching Program, the Internship Review Committee, the revised "Essentials of an Approved Internship," the Residency Review Committees, and the Sears Roebuck Foundation; a brief report on foreign medical school graduates serving internships and residencies in approved hospitals; and the plan for future evaluation of the qualifications of foreign physicians who wish to come to this country for further medical training.

Each hospital approved for intern and/or resident training furnished detailed information regarding its training programs, and the material presented is based on this submitted information. The statistical data in the tables represent the intern and resident situations as of Sept. 1, 1955. Consequently, these figures are in some instances at variance with those presented in the lists of approved services, as the latter refer to appointments for the year beginning July 1, 1957.

Specially arranged lists of hospitals offering approved internships and residencies are published following the report. The first listing of hospitals includes those approved for the training of interns, listed according to location. As in previous years, information also includes the number of hospital beds, the number of annual admissions, the autopsy rate, the length of the program, the stipend, and the number and types of intern positions offered. A subsequent classification lists these hospitals according to types of internships.

In the residency section, the hospitals approved for resident training are listed according to medical specialties, giving statistical data, names of chiefs of services and additional pertinent information similar to that included in the internship section. Following this listing, hospitals approved for resident training are listed by state and city, giving the specialties for which each is approved.

This Annual Report and the lists referred to are reprinted as the Directory of Approved Internships and Residencies. The Council will furnish copies of this directory upon request.

The Council acknowledges the cooperation and assistance of medical staffs and hospital administrators, who have made the publication of this report possible by furnishing the statistical data on which it is based. The following organizations collaborated in approving residency programs:

- Advisory Board for Medical Specialties
- American Academy of General Practice
- American Board of Anesthesiology
- American Board of Dermatology
- American Board of Internal Medicine
  - Subspecialty Board on Allergy
  - Subspecialty Board on Cardiovascular Disease
  - Subspecialty Board on Gastroenterology
  - Subspecialty Board on Pulmonary Diseases
- American Board of Neurological Surgery
- American Board of Obstetrics and Gynecology
- American Board of Ophthalmology
- American Board of Orthopedic Surgery
- American Board of Otolaryngology
- American Board of Pathology
- American Board of Pediatrics
  - Subspecialty Board on Allergy
- American Board of Physical Medicine and Rehabilitation
- American Board of Plastic Surgery
- American Board of Preventive Medicine
- American Board of Proctology
- American Board of Psychiatry and Neurology
- American Board of Radiology
- American Board of Surgery
- American Board of Urology
- Board of Thoracic Surgery
- American College of Physicians
- American College of Surgeons

The Annual Report furnishes information on medical education at the internship and residency levels to medical students, medical educators, hospital administrators, and the entire medical profession. It is hoped that this information will also be of assistance to physicians beginning their professional careers who desire to further their medical education.

INTERNSHIPS

The number of hospitals approved for intern training and the number of approved internships are indicated in table 1. There were 867 approved hospitals offering 11,616 positions for the intern year beginning July 1, 1955, as compared with 850 approved hospitals

---

Miss Mary A. McGovern and Mrs. Helen Neitzel were responsible for much of the detail work in the preparation of the list of approved internships and residencies and the staff of the Bureau of Economic Research were responsible for the IBM statistical tabulations.

and 11,048 positions for the previous year, representing an increase of 17 hospitals (2%) and 568 internships (5%). The increase in the number of approved hospitals for the past 10 years is 14% (103 hospitals) and 3,077 internships (35%). Last year, the average number of interns per hospital was 12.9, as compared with the present figure of 13.3.

Hospitals outside the continental United States that are approved for intern training are represented by one in the Canal Zone; four in Hawaii; and seven in Puerto Rico.

In 1956, there were 6,845 graduates of approved American medical schools. When this figure is compared with the number of intern positions offered, there is a disparity of about 4,500 between the number of approved internships and the number of American graduates available to fill these positions. As stated later in this report, almost half of these vacancies were filled by graduates of foreign medical schools on Sept. 1, 1955. The number of vacant internships for the reported year is comparable to the number reported for the previous year, as indicated later in this report.

TABLE 1—*Approved Hospitals and Internships, 1947-1956*

Yr. of Publication	No. of Hospitals	No. of Internships*
1947	761	8,539
1948	807	9,118
1949	807	9,124
50	790	9,398
	828	10,044
	865	11,467
	856	11,006
	844	10,624
	850	11,048
95	867	11,616

*U. S. Army and U. S. Navy hospitals and those outside the United States not included in 1947 figures.

Since the Council published its first list of approved hospitals in 1914, there has been an increase of 44% in the number of approved hospitals and an increase of 275% in the number of approved internships.

Internships, by Type of Service

Table 2 gives a breakdown of approved internships by type of service, including the number and the percentage reported filled and vacant on Sept. 1, 1955. The total number of internships offered was 11,616. The total number of approved hospitals was 867; these hospitals offered 1,080 approved intern training programs. For the past three years, the percentage of rotating, straight, and mixed internships offered has not varied appreciably, with 89% rotating, 10% straight, and 1% mixed (fig. 1). Rotating services include both rotating general and rotating with emphasis on a particular service. Straight internships include straight service assignments to internal medicine, surgery, pediatrics, obstetrics-gynecology, and pathology. Mixed internships include services on which assignments are made to two or three of the four major services.

There is a slight increase (1%) in the over-all number of intern positions filled this year as compared to last year. Rotating internships were 83% filled on Sept. 1, 1955, straight internships 83%, and mixed internships 84%. These figures do not vary greatly from those quoted for the preceding year. Intern positions in obstetrics-gynecology increased from 40% to 60%, those in pathology from 57% to 64%. The number of vacant internships increased from 1,982 for the previous year to 2,013 for 1955. The number of filled positions increased from 9,066 (1954) to 9,603 (1955). The increased number of internships filled is attributed to an increase of foreign medical school graduates serving as interns, including both foreign medical school graduates having temporary visas and those having permanent visas.

TABLE 2.—*Number of Internships, by Type of Service, 1955-1956*

Type of Internship	No. of Approved Programs	No. of Internships Filled Sept. 1, 1955	 Vacant Sept. 1, 1955	 Percentage Filled
Rotating general	813	8,363	1,766	83
Other rotating	29	63	26	71
Totals	842	8,426	1,792	83
Mixed	25	114	21	84
Straight				
Internal medicine	73	563	62	90
Surgery	64	318	78	80
Pediatrics	44	129	28	82
Obstetrics-gynecology	8	21	14	60
Pathology	24	32	18	64
Totals	213	1,063	200	83
Grand totals	1,080*	9,603	2,013	83

* Number of intern-training programs in 867 approved hospitals.

In the revised "Essentials of an Approved Internship," adopted by the House of Delegates on Dec. 1, 1955, straight internships in pathology were continued. Approval for straight internships in obstetrics-gynecology has been discontinued, effective June 30, 1957. Two resolutions were introduced into the House of Delegates at the June, 1956, Annual Session in Chicago favoring the rotating internship. The Reference Committee on Medical Education and Hospitals made the following report concerning these resolutions:

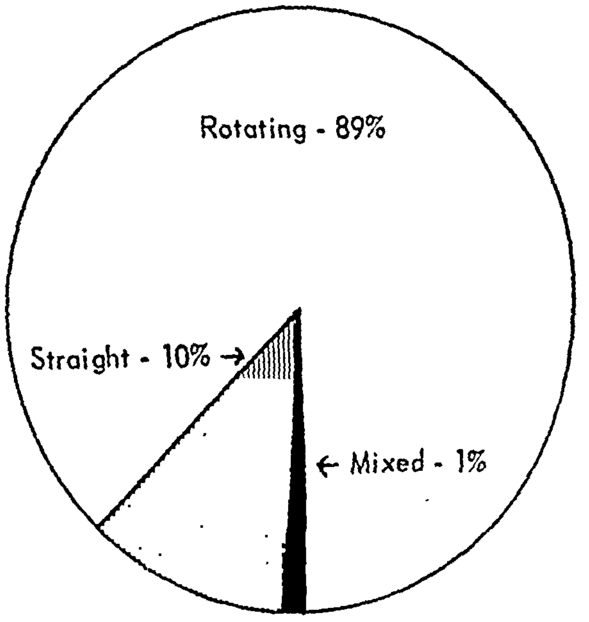

Fig. 1. Types of approved internships, 1953-1956.

> The Reference Committee believes that there is a growing body of opinion within the profession in favor of a rotating internship. It also recognizes the difficulties involved and the dangers to some established education programs were action taken precipitously to disapprove straight internships, which are about 10% of the total number now approved. It recommends the following substitute resolution for resolutions 11 and 38:

"*Resolved*, 1. That the Council on Medical Education and Hospitals be requested to increase its efforts to encourage rotating internships rather than straight internships in all hospitals approved for the latter.

"2. That a report of the results of this effort be submitted annually."

This portion of the report of the Reference Committee was adopted by the House of Delegates. The problem of the straight internship is not one that can be solved easily. It will require careful analysis and study over a period of time by medical educators, hospital administrators, and the professional staffs of hospitals.

Internships, by Type of Hospital Control

In table 3 the distribution of internships according to hospital control is indicated. Federal hospitals offered 603 (5%) of the 11,616 approved internships; nonfederal governmental hospitals offered 3,591 (31%) of the available internships; nongovernmental institutions offered 7,350 (63%) positions; and 72 internships (less than 1%) were offered by proprietary hospitals.

TABLE 3.—*Number of Internships, by Type of Hospital Control, 1955-1956*

Control	No. of Approved Hospitals	No. of Internships: Filled Sept. 1, 1955	Vacant Sept. 1, 1955	Percentage Filled
Federal				
U. S. Army	7	187	...	100
U. S. Navy	17	176	...	100
U. S. Public Health Service	7	84	1	99
Veterans Administration	7	55	44	55
Other federal	3	48	8	86
Totals	41	550	53	93
Governmental (nonfederal)				
State	27	783	67	92
County	35	804	53	94
City	53	1,317	149	89
City-county	16	316	42	88
Totals	131	3,280*	311	91
Nongovernmental				
Church operated and related	294	2,244	768	74

Corporations unrestricted as to profit	9	44	12	79
Totals	11	60	12	83
Grand totals	867	9,603	2,013	83

The group of federal hospitals had the highest occupancy rate for interns, 93%, on Sept. 1, 1955. The Army hospitals and the Navy hospitals had a full complement, and the Public Health Service had a 99% occupancy rate. The nonfederal governmental hospitals had 91% of their positions filled; county hospitals had the highest rate in this group, 94%. The rate for the nongovernmental hospitals was 78% and for the proprietary hospitals was 79%.

The federal hospitals showed an increase in occupancy rate of 4% over the rate for the previous year. There was a 1% increase for the nonfederal governmental hospitals and an increase of 12% for the proprietary hospitals. The rate for the nongovernmental hospitals remained at the same figure as quoted for 1954.

The average number of internships filled for federal hospitals was 13.4 per hospital; for nonfederal governmental hospitals, 25.0; for nongovernmental hospitals, 8.4; and for proprietary hospitals 5.5. The average numbers of intern positions offered per hospital, considering all hospitals, was 13.3; the average number of interns on duty per hospital was 11.1.

In 1953, 8,275 internships were filled (78%); in 1954, 9,066 positions were filled (82%); and in 1955, 9,603 positions were filled (83%).

Internships, by Medical School Affiliation and Bed Capacity

The classification of hospitals into the categories of "major teaching," "minor teaching," and "nonaffiliated" is used in this report and in the following list of approved internships. These classifications are based on the degree to which medical schools utilize the hospitals for undergraduate medical education. A "major teaching" hospital is considered by the school as being a major unit in its undergraduate clinical clerkship program. A "minor teaching" hospital is one that is utilized to a limited extent for undergraduate instruction. A "nonaffiliated" hospital is one that is not designated by a medical school as participating in such a program. Based on this classification, a statistical analysis of approved internships is presented in table 4.

TABLE 4.—*Number of Internships, by Medical School Affiliation and Bed Capacity, 1955-1956*

Classification	No. of Approved Hospitals	No. of Internships: Filled Sept. 1, 1955	Vacant Sept. 1, 1955	Percentage Filled
Nonaffiliated				
Less than 200 beds	167	753	214	78
200-299	258	1,651	561	75
300-499	178	1,803	452	80
500-over	51	952	132	88
Totals	654	5,159	1,359	79
Major teaching				
Less than 200 beds	11	77	40	66
200-299	19	227	54	81
300-499	52	893	131	87
500-over	65	2,591	236	92
Totals	147	3,794	461	89
Minor teaching				
Less than 200 beds	13	41	29	59
200-299	22	156	65	71
300-499	21	237	67	78
500-over	10	216	32	89
Totals	66	650	193	77
Grand totals	867	9,603	2,013	83

Major teaching hospitals (147) constituted 17% of the approved hospitals for the past year and offered 4,255 internships with an occupancy rate of 89%. Minor teaching hospitals (66), 8% of the approved hospitals, offered 843 internships, of which number 77% were filled. Nonaffiliated hospitals (654) were 75% of the total number of approved hospitals; 79% of the 6,518 positions offered by this group were filled on Sept. 1, 1955.

The rate of occupancy for approved hospitals was highest in the major teaching group, the rate being 89%. This figure was 4% higher than that for last year. The rates for the minor teaching and nonaffiliated hospitals were 77% and 79% respectively.

A study of the occupancy rate for these three groups of hospitals indicates that there is a definite trend for the larger hospitals to have a higher occupancy rate than the smaller hospitals. The combined occupancy rate for hospitals of less than 200 beds in all groups was 76%; that for hospitals of 500 beds or more in all groups was 90%. The trend in all three groups of hospitals in these classifications was that, as the size of the hospital increased, the occupancy rate increased.

Internships, by Census Region and State

A breakdown by states and regions of the internships filled and vacant on Sept. 1, 1955, is shown in table 5. As compared with the regional figures for positions occupied with those of last year, there is no great change for any region. The highest regional figure for occupany was in those hospitals outside the continental United States, the Canal Zone, Hawaii, and Puerto Rico, which had 96% of their intern positions filled. In the United States, the Pacific region with 87% again had the highest rate, although the New England and the Middle Atlantic regions had rates of 86% and 85% respectively. The lowest rate occurred in the East South Central region, the rate being 73%, a slight increase over last year's rate. Individual states having 90% occupancy or better were South Carolina, Connecticut, Vermont, Ohio, New York, New Jersey, District of Columbia, Louisiana, Arizona, Washington, Canal Zone (100%), Hawaii, and Puerto Rico. States with rates below 50% were North Dakota and Montana.

As could be expected from a study of the population of the United States, one-fourth of the approved hospitals are located in New York, New Jersey, and Pennsylvania. One-fourth of the filled internships occur in these states. Pennsylvania ranks lowest in rate of occupancy for the Middle Atlantic states, with 71%. As indicated previously, the occupancy rate for internships shows a 1% increase over last year. On Sept. 1, 1955, no approved internships were offered in Idaho, New Mexico, Nevada, and Wyoming.

Internship Stipends

There has been an increase in the average monthly cash stipend paid the intern in both affiliated and nonaffiliated hospitals. The average monthly stipend paid by the affiliated hospital for 1954 was $87; the figure for 1955 is $121, an increase of $34. For 1954, the stipend paid by the nonaffiliated hospital was $136, as compared with $169 for 1955.

Eighty-five per cent of the affiliated hospitals furnish full maintenance in addition to the stipend; 15% offer partial maintenance; 60% give additional perquisites such as uniforms and bonuses. Only three hospitals do not pay a cash stipend.

In the group of nonaffiliated hospitals, 88% furnish full maintenance, 10% partial maintenance. Twenty-one hospitals do not offer maintenance; more than half of the hospitals in this group reported additional perquisites for the interns. (All federal hospitals have been excluded from data regarding stipends.)

Figure 2 compares the range of stipends paid by affiliated and nonaffiliated hospitals. Although the average stipend paid by the affiliated hospital is $38 less than that paid by the nonaffiliated hospital, the occu-

pancy rate for the former was about 10% higher than for the latter. From this fact, it is logical to conclude that financial consideration is not the decisive factor in choosing an internship. The letters FM and PM following the stipend quoted in the list of approved internships refer to "full maintenance" and "partial maintenance."

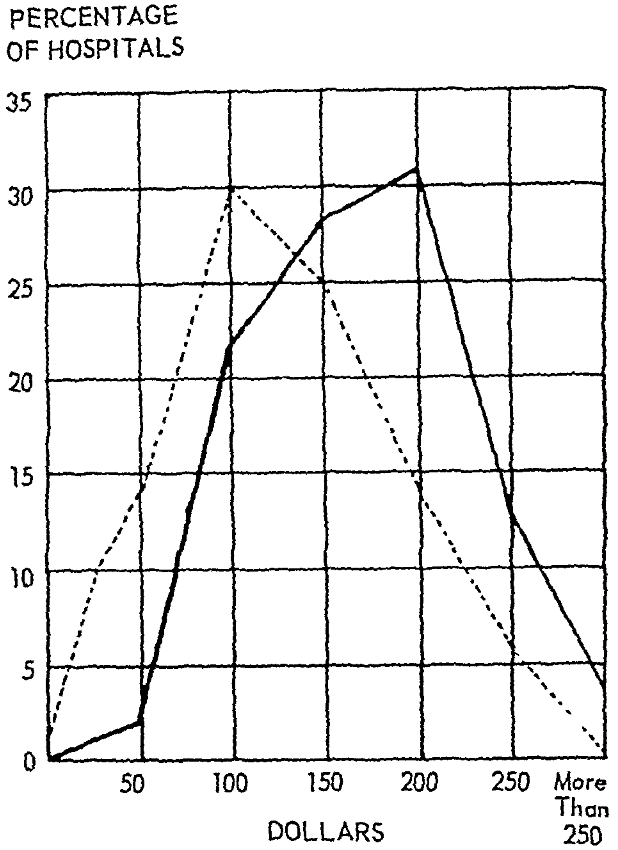

Fig 2 Monthly internship stipends, with federal hospitals excluded Solid line indicates nonaffiliated hospitals (206), dashed line affiliated hospitals (200). Abscissa gives upper level of stipend range

Autopsy Rates

It is a specific requirement for internship approval that hospitals maintain a minimum autopsy rate on hospital deaths of 25%. If an approved hospital does not maintain a 25% rate for two consecutive years, approval may be withdrawn. The autopsy rate is considered an accurate index of the interest of the medical staff and the hospital administration in scientific medical progress. Hospitals that consistently maintain a high autopsy rate display a sincere interest in medical education.

Table 6 lists the 20 federal hospitals and the 20 nonfederal hospitals conducting internships during the past year that had the highest autopsy rates for the reported period (1955). These hospitals are to be commended for their excellent work in this connection.

Fifteen hospitals (2%) had autopsy rates of less than the required 25%. These hospitals have been advised of their failure to meet the requirement and will be required to raise the rate for the next reporting period in order to qualify for continued approval.

National Intern Matching Program

The National Intern Matching Program has completed five years of successful operation as the agency through which medical school graduates receive appointments as interns in hospitals approved for such training by the Council on Medical Education and Hospitals. The primary function of the Program is to serve as a central clearing agency for medical students and hospitals; its aim is to provide an orderly method for giving effect to students' preferences regarding hospitals and hospitals' choice of students in the appointment of interns. This mechanical plan of matching interns and hospitals has proved more efficient than any other plan previously used and gives complete freedom of choice to both students and hospitals.

The policies under which the program operates are determined by organizations interested in internships. In addition to the Council on Medical Education and Hospitals, these organizations are the American Hospital Association, the Association of American Medical Colleges, the American Protestant Hospital Association, the Catholic Hospital Association, and the Student American Medical Association. The policy-making body of the National Intern Matching Program is composed of representatives from these groups. liaison representatives from the Federal Services, and a student representative

Hospitals eligible to participate in the program must be approved by the Council on Medical Education and Hospitals. Students eligible to join the program are those seeking first-year internships in these hospitals. Each student is provided with a Directory of Participating Hospitals, and each hospital receives a Directory of Participating Students. Students apply where they wish, to as many hospitals as they desire. Hospitals are free to interview any participating student and use their own interview and evaluation techniques. Upon completion of interview, each student submits to the Program office a ranking list showing the hospitals to which he has applied in order of preference. Hospitals also submit ranking lists of students who have applied to them. These lists, together with the intern quotas for each hospital, form the basis of the matching operation. Hospitals are matched with those students ranked highest on their list to the limit of their quota, unless those students prefer another hospital which also has given them a high ranking. Thus each student receives the highest choice hospital on his list that has a place for him. It is the individual responsibility of student and hospital to determine what will be acceptable to them prior to submitting ranking lists. The Program covers internships beginning between April 1 and Dec. 31. Lists are received by the National Intern Matching Program in January; the actual matching begins in February; and results are announced the middle of March.

Participation in the fifth program, completed in March 1956, included 98% of all hospitals approved by the Council and 97% of all United States medical school seniors. Of the 6,821 students in the program, 6,588 (97%) were matched. Of the 233 unmatched students, more than 100 applied to only one or two hospitals, thereby reducing their chances of being matched. Of the students matched, 74% received their first choice, 15% their second choice, 6% their third choice, and 5% their fourth choice or lower.

There were 11,459 positions offered by the 821 participating hospitals; 17% of these hospitals completely filled their quotas, 53% partially filled them, and 30% of these hospitals had no interns matched to them.

During the past year, hospital and student participation was at the highest level in the history of the program. Indications are that participation in the Program for 1957-1958 will equal and probably surpass previous years.

Internship Review Committee

The Internship Review Committee was established in 1954 and is composed of representatives of organizations concerned with and interested in intern training programs. In addition to the representatives of the Council on Medical Education and Hospitals, there is a representative from the Association of American Medical Colleges; the American Hospital Association, the Federation of State Medical Boards of the United States; and the American Academy of General Practice.

The purposes of the Committee are (1) to review reports of surveys of intern training programs and make recommendation to the Council for approval or disapproval; (2) to recommend to the Council such revisions of the requirements for intern education as are considered appropriate; and (3) to recommend to the Council such revisions in policy concerning all aspects of intern education as are considered appropriate.

In its period of operation, the Committee has become increasingly aware of the necessity for reasonable flexibility in the interpretation of the requirements for internship approval and of the advisability of giving a hospital an opportunity to bring its deficient program of training up to standard before approval is withdrawn. When a hospital does not measure up to the requirements for approval, it is warned that its approved status is in jeopardy and advised regarding the specific corrections that should be made. Sufficient time for correction of these deficiencies is permitted before approval is actually withdrawn. This policy serves to emphasize the consultant attitude of the Committee and of the Council in respect to training programs.

The Committee is functioning effectively and is filling a real need in its work. It is currently doing a great deal to maintain and improve the standards of intern education and is continually working toward this objective.

Revised Essentials of an Approved Internship

The House of Delegates adopted the revised "Essentials of an Approved Internship" as presented by the Council on Dec. 1, 1955. This revision incorporated the changes and recommendations made by the Ad Hoc Committee on Internships. The principal changes made were 1. The "one-fourth rule" will be applied. 2. Straight internships in pathology will be approved 3 Stress was placed upon the educational function of the internship as being primary.

The "one-fourth rule" states: "A hospital which for two successive years does not obtain one-fourth of its stated complement of interns may be disapproved for intern training." Early in January, 1956, a copy of the revised Essentials was sent to the Administrator and to the Chairman of the Intern Committee in each hospital approved for the training of interns; attention was called to the "one-fourth rule" in the covering letter. In May, 1956, the following interpretation was given by the Council staff to this rule:

1. All interns serving in a hospital are considered in computing the percentage of quota filled; this includes graduates of both American and foreign medical schools.

2. The percentage of the quota filled will be calculated on the basis of (*a*) the quota published in the 1955 Internship and Residency Number of THE JOURNAL, (*b*) the number of interns on duty on Sept. 1, 1956, as reported by the hospital. (Similar statistics will furnish the basis for computing the percentage of quota filled in following years.)

3. If an approved hospital fails to meet the requirements of the "one-fourth rule," a letter of warning will be sent to the hospital the first year; if it does not fill the required percentage for two successive years, approval may be withdrawn.

4. Intern quotas may be changed upon written request to the Council.

5 Application of the "one-fourth rule" will obtain beginning in January, 1958. Any approved hospital that does not fill one-fourth of its intern quota for the two successive years 1956-1957 and 1957-1958 may have its internship approval removed at that time.

In the revised Essentials it is specifically pointed out that if the primary function of the internship is not educational. approval is in jeopardy.

✓

Interns and Residents from Foreign Countries

The Institute of International Education conducted a survey in September, 1955, of foreign medical school graduates serving internships and residencies in hospitals approved for this training by the Council on Medical Education and Hospitals.[1] These foreign physicians came from 84 countries and were nonimmigrants, expecting to return to their own countries on completion of their medical training.

There were 6,033 foreign physicians reported by McCormack and Feraru [1] in this study serving as members of the house staffs of approved hospitals, an increase of 20% over the figures determined in a similar survey in September, 1954. Of this number, 1,859 were interns and 4,174 were residents. The six countries having the largest representation were: the Philippine Islands, 1,065; Canada, 584; Mexico, 489; Germany, 364; Turkey, 320; and Italy, 260. These six countries were listed in the same order in last year's survey.

One-fourth (1,533) of these foreign physicians were located in New York. There were 485 in Ohio; 415 in Pennsylvania; 398 in New Jersey; 371 in Massachusetts; and 359 in Illinois. The two largest groups receiving resident training were in general medicine and general surgery; obstetrics-gynecology and pathology ranked third and fourth, respectively, in numbers.

The present policy of the Council is that graduates of foreign medical schools may be appointed to the intern and resident staff of a hospital without jeopardizing the approved status of the hospital. However, following the adoption of the report of the Cooperating Committee on Evaluation of Graduates of Foreign Medical Schools by the House of Delegates at the Annual Session in June, 1956, in Chicago, plans are now being crystallized for evaluation of foreign physicians coming to the United States to serve internships and residencies. The proposed program of evaluation is outlined in the Report of the Council on Medical Education and Hospitals.[2] The emphasis in this program is placed on the evaluation of the medical qualifications of the individual foreign-trained physician who wishes to come to the United States. The program is designed to establish two principal criteria in regard to each foreign-trained physician: (1) that he is a graduate of a bona fide medical school; and (2) that, as nearly as can be measured, he has reached a level of educational attainment comparable to that of students in American schools at the time of graduation. These criteria are to be established by evaluation of the physician's medical credentials in view of predetermined minimal standards and examination of the physician for factual knowledge of medicine.

It is believed that implementation of this proposed program will afford hospitals needed assurance in regard to the medical qualifications of foreign-trained physicians seeking positions as interns and residents. It is anticipated that this program will be in effect in one year.

THE SEARS ROEBUCK FOUNDATION

Physicians completing their graduate training and who may require financial assistance in initiating the establishment of medical practice units in areas considered medically deficient will be interested in investigating the program financed by the Sears Roebuck Foundation. This Foundation has made two grants of $125,000 to a revolving assistance fund administered by a Medical Advisory Board appointed by the Trustees of the American Medical Association. These grants are dispersed by the Board in the form of 10-year, nonsecured, supplemental loans ranging from $1,000 to $25,000. Interest ranges from zero to 6%, depending on the rapidity of payment. All loans are designed to make up the difference between what can be raised through normal lending agencies and the total amount needed. All funds collected in the form of interest and principal go into the revolving fund, thereby making the program self-perpetuating and providing the "seed" principal of growth and expansion at the same time. It is estimated that, within 10 years, this fund will amount to over $2,000,000 because of this growth factor, which will do much to meet the needs of medical distribution.

The purpose of the plan is to encourage physicians to locate in communities where their services are most urgently needed. Because of the limited funds available at this time, all loans are competitive, thereby insuring that loans reach communities and physicians with the greatest need. Preference is given to physicians—specialists or general practitioners—who desire to go to rural or rapidly growing suburban areas where medical care in inadequate.

All applications are reviewed by the territorial or area Medical Advisory Board members, where they are approved or rejected. If approved, they are then presented to the entire Board, where all applications approved by the various area Advisory Boards are reviewed and final decisions made. The Board reviews applications on the following grounds:

1. Professional qualifications.
2. Availability and quality of medical service in the community. (Loans are intended primarily to create units, but consideration is also given to improving and expanding existing units.)
3. Soundness of the plan for providing medical care.
4. Financial initiative of applicant, thus insuring that loans are supplemental.
5. No loan will be granted for the purpose of refinancing existing debt or to be used for cost of living while establishing practice.

This statement regarding the Sears Roebuck Foundation is presented in this issue of The Journal for the information of medical school and hospital administrators, officials of local and state medical societies, and others whose advice is sought by young physicians in regard to sources of financial assistance. Physicians interested in applying for the Sears Roebuck assistance should contact their school, hospital, or county or state medical society for applications and more detailed information.

RESIDENCIES

Residency training in the United States continues to expand. The Council now approves residencies in 30 specialties and subspecialties, aviation medicine having been added in the past year. These programs are conducted in 1,202 general or special hospitals. Residency Review Committees, composed of representatives of the Council and the appropriate American Board, have been organized in dermatology, neurological surgery, ophthalmology, orthopedic surgery, pediatrics, physical medicine, preventive medicine, proctology, psychiatry, radiology, and urology. Residency Review Committees in surgery, plastic surgery, and otolaryngology include representatives of the American College of Surgeons, and the American College of Physicians is represented on the Committee for internal medicine. In four specialties, anesthesiology, obstetrics-gynecology, pathology, and thoracic surgery, the Council approved programs in concurrence with the board concerned with each organization taking unilateral action.

* Full training including children's orthopedics.
† Full training without children's orthopedics.
‡ Less than full training.
§ Surgery A includes programs leading to certification by the American Board of Surgery.
‖ Surgery B includes programs approved as offering training in general surgery in preparation for a residency in a surgical specialty.

The following section of the report presents statistical data on the number of residencies by type of hospital control and by bed capacities of the hospital in which the training is conducted. The number of residencies filled and vacant represent the situation as of Sept. 1, 1955. The total number of residency appointments available increased from 25,486 reported last year to 26,516 this year, an increase of 4.5%. The number of residents serving rose from 20,494 to 21,425, also about 4.5%. The percentage of residencies filled was 81%, or almost exactly the same as it had been for the two years immediately preceding. These figures seem to indicate that although the number of residency positions increased the rate of increase was smaller than that of the previous year, when 1,858 positions were added, an increase of 8%.

Number of Residencies, by Specialties

Table 7 presents a breakdown by specialties of the number of approved programs, the number of first-year appointments filled and vacant as of Sept. 1, 1955, and the total number of appointments filled and vacant for the same date. There were 5,043 separate residency programs conducted last year, and they offered a total of 26,516 appointments, including 11,328 at the first-year level.

The number of hospitals approved for training varied from one offering training in occupational medicine to 609 offering training in internal medicine. Eight specialties—internal medicine, obstetrics and gynecology, pathology, pediatrics, psychiatry, radiology, and surgery—accounted for more than three-fourths of all residencies offered, with 20,245 positions out of a total of 26,516. There were less than 100 appointments in each of the following specialties: allergy, 35; cardiovascular disease, 81; contagious disease, 10; gastroenterology, 63; malignant diseases, 29; plastic surgery, 91; proctology, 29; occupational medicine, 2.

The percentage range of first-year residencies filled varied from 36.2% of those in physical medicine to 91.1% of those in obstetrics. Similarly, for appointments at all levels, the percentage filled in physical medicine was the lowest, 43.4%, while those in straight gynecology had the highest occupancy rate, 95.6%.

Of those specialties constituting the majority of residencies offered, pathology, as last year, showed the lowest occupancy rate for all years 64.5% (first-year through fourth-year appointments), while surgery showed the highest, 90.7%. Specialties in which more than 25% of residencies were vacant included the following: allergy, general practice, neurology, pathology, physical medicine, proctology, psychiatry, and pulmonary disease. It should be noted that a relatively high number of appointments were offered in both pathology and psychiatry.

The percentage of first-year positions filled, 79.5%, was approximately the same as those filled at all levels, 80.8%.

In summary, the increase of residency appointments, both absolute and percentage-wise, was less in 1955-1956 than in 1954-1955, and the percentages of occupancy at all levels remained approximately the same.

Residencies, by Type of Hospital Control

A breakdown of residency appointment by type of hospital control is presented in table 8. Residency programs were offered in 120 federal hospitals, 315 other governmental (nonfederal) hospitals, 737 nongovernment institutions, and 30 proprietary hospitals. The total number of residency appointments was about equally divided between governmental and nongovernmental hospitals, with those in the former category offering 13,108 residencies and those in the latter, 13,408.

The Veterans Administration accounted for about three-fourths of the total, with 3,067 residency positions offered out of 4,065 for all federal hospitals. The occupancy rate for all federal hospitals, including the Veterans Administration, was 73.2%, slightly below that for the nation as a whole. Comparable figures for last year showed 72% of residencies in federal hospitals filled, and 80% for all hospitals. Considering appointments in all categories, the occupancy rate varied from 53.8% in United States Air Force hospitals to 87.3% in city-controlled hospitals. Since only three hospitals, offering only 20 programs with 89 available positions, are included in the category "other federal," it does not seem statistically sound to compare the percentage of positions filled, 94.4%, with those of the larger groups of government hospitals. Considering appointments in all categories, the occupancy rate varied from 56% in United States Army hospitals to 87.3% in city-controlled institutions. If first-year appointments only are considered, the disparity in occupancy rates between federal and all other hospitals is even more marked. The United States Army reported 56% of their first-year appointments filled, the United States Navy 60%, the United States Air Force 60%, the Veterans Administration 67.7%, the United States Public Health Service 92.1%, and other federal hospitals 90.3%. The rates for other governmental (nonfederal) hospitals did not vary so widely, ranging from 80.3% for state-controlled institutions to 86.1% for those that were county-controlled. The total number of residencies offered by federal institutions did not change appreciably, although there was a slight decrease, with a slight increase in occupancy rate.
